VARIABILITY OF IRIS.—The results of a number of photometric measurements of the apparent brightness of Iris, carried out by Dr. H. Clemens during February and March, 1904, are given in No. 4063 of the *Astronomische Nachrichten*.

The lowest magnitude was recorded at 10h. 15m. (M.E.T.) on March 28, and was 10·34; the highest maximum observed (8·80) took place on February 9 at 8h. 46m. From the consideration of his results, Dr. Clemens concludes that Iris has a real variation of magnitude amounting to 0·25m.–0·30m., and having a period of approximately four hours.

SOME QUESTIONS FOR ARCHÆOLOGISTS.

THE study of a few of our British stone monuments from an astronomical point of view has led me to the conclusion that if such an inquiry be continued information will ultimately be obtained touching the order of succession of the various swarms of immigrants who set out the various systems of alignments. Approximate dates of the changes of temple worship representing different cults, and, therefore, possibly different tribes, have already been obtained, for I have evidence that the risings of stars, as well as of the sun, were observed in some of the circles. I also believe that much folklore and many myths may find their explanation.

I begin with the fact that some circles used in the worship of the May year were in operation 2000 B.C., and there was a change of cult about 1600 B.C., or shortly afterwards, in southern Britain, so definite that the changes in the chief orientation lines in the stone circles can be traced.

To the worship of the sun in May, August, November, and February was added a solstitial worship in June and December.

The easiest explanation is the advent of a new swarm of immigrants about that date.

The associated phenomena are that the May–November Balder and Beltaine people made much of the rowan and maythorn. The June–December people brought the worship of the mistletoe.

The flowering of the rowan and thorntree in May, and their berries in early November, made them the most appropriate and striking floral accompaniments of the May and November worships, and the same ideas would point to a similar use of the mistletoe in June and December.

Another associated phenomenon is that chambered barrows seem sometimes to have been used by the solstitial people instead of, or in addition to, stones to mark sight-lines.

If there were such swarms, and the June–December succeeded and largely replaced the May–November one, this could hardly have been put in a cryptic and poetic statement more happily than it appears in folklore: Balder was killed by mistletoe.

In the May–November circles and alignments we deal with unhewn stones. In the June–December alignments the stones in Brittany are tooled.

In this we have a strong argument in favour of the same order of succession.

The Worship Conditions and a Working Hypothesis.

In a colony of the astronomer-priests who built and used the ancient temples we had of necessity:—

(1) Observatories, *i.e.* circles, alignments, coves or holed stones, for viewing the alignments or sight-lines.

A study of the sight-lines shows us that the stones—collimation marks—were of set purposes, placed some distance away from the circles, so far that they would be required to be illuminated in some way for the dawn observations. When there was no wind, one or more hollows in a stone, whether a menhir or a quoit, might have held oil or grease to feed a wick. But in a wind some shelter would be necessary, and the light might have been used in a cromlech or allée couverte. Stones have been found with such cups, and débris of fires have been found in cromlechs.

(2) Dwellings, which would be cromlechs or many-chambered barrows, according to the number of astronomer-priests at the station, and possibly some arrangement for protecting a sacred fire.

(3) A water supply for drinking and bathing, which might be a spring, river or lake, according to the locality.

Assuming this, I ask whether we may not consider the following working hypothesis, the accuracy of which can be easily tested by those conversant with these subjects, which I am not; nor have I time to look over the vast and scattered literature where the facts are recorded.

Everything relating to these three different classes of things was regarded as very holy, because they were closely associated with the astronomer-priests, on whom the early peoples depended for guidance in all things, not only of economic, but of religious, medical and superstitious value.

Hence the circles, mounds and alignments, as sacred places, were subsequently used for burials, as Westminster Abbey has been; but burials were not the object of their erection by the first swarms.[1] I believe they were afterwards used for burials by later swarms, who imitated them, and built round barrows without living chambers for the dead.

The perforated stones were regarded as sacred, so that marriages took place at them, and passing through them was supposed to cure disease. Whether men and women, or children only, passed through the hole depended upon its size. But a hole large enough for a head to be inserted was good for head complaints. I may state that I have traced holed stones on May-November alignments. In too many cases the temples connected with them have been so ruthlessly destroyed that their use cannot so easily be established.

The cups for the light would also become sacred objects; have not many of them since been used for holy water?

The wells, rivers, and lakes used by the priests were, as holy places, invested with curative properties, and offerings of garments (skins?), and pins to fasten them on, were made at them to the priests, as well as bread and wine and cheese.

The fact that the tree on which the garment was hung was either a rowan or a thorn shows that these offerings commenced as early as the May November worship.

These wells are in many cases alongside cromlechs, circles or unhewn stones. In others they are near churches which have been built upon the sites of the more ancient temples.

At the coming of the June–December people all the old practices and superstitions were retained, only the time of year at which they took place was changed. As the change of cult was slow, in any one locality the celebrations would be continued at *both* times of the year.

The June–December people did what they could to favour their own cult by changing the old holidays, with the result that for long both sets of holidays were retained.

Since I have shown that the solstitial worship came last, as a rule traces of this would be most obvious in places where it eventually prevailed over the cult of the May year. In such places the absence of traces of the May festival would afford no valid argument against its former prevalence. In other places, like Scotland, where the solstitial cult was apparently introduced late and was never prevalent, we should expect strong traces of the May worship, and, as a matter of fact, it is very evident in the folk-lore and customs of Scotland.

The Conditions of Migration.

May we suppose that any of the races reached Britain by sea?

Some facts with regard to ancient travel are the following. Our start-point may be that Gudea, a Babylonian king who reigned about 2500 B.C., brought stones from Melukhkha and Makan, that is, Egypt and Sinai (Budge, "History of Egypt," ii., 130). Now these stones were taken coastwise from Sinai to Eridu, at the head of the Persian Gulf, a distance of 4000 miles, and it is also said that then, or even before then, there was a coastwise traffic to Malabar, where teak was got to be used in house-building. The distance from Eridu coastwise to Malabar, say the present Cannanore, is 2400 miles.

The distance, coastwise, from Alexandria to Sandwich, where we learn that Phœnicians and others shipped the tin extracted from the mines in Cornwall, is only 5300 miles, so that a voyage of this length was quite within the powers of the compassless navigators of 2500 B.C.

The old idea that the ancient merchants could make a course from Ushant to, say, Falmouth or Penzance need no longer be entertained; the crossing from Africa to Gibraltar and from Cape Grisnez to Sandwich were both to visible land, *i.e.* coastwise. The cliffs on the opposite land are easily seen on a clear day.

Hence it would have been easier before the days of astronomical knowledge and compasses to have reached

[1] "Les Celtes et les Gaulois dans les Vallées du Pô et du Danube," p. 82.

England, and therefore Ireland and the Orkneys, than to get to some of the islands in the Mediterranean itself; and the prevalence of solstitial customs in Sardinia and Corsica, with apparently no trace of the May year, tends to support this view, which is also strengthened by the fact that the solstitial customs in Morocco are very similar to those we read of in Britain.[1] The May year is unnoticed, and there is a second feast at Easter (March 16).

The May Year.

I traced the May year in Egypt at Thebes, the temple being that of Min, and the possible date 3200 B.C. Mr. Penrose showed that the Hecatompedon and the Archaic temple of Minerva at Athens were May temples, the dates of the foundations being 1495 B.C. and 2020 B.C. respectively; but the cult must have been there before the foundations; and the cult may well have come from Thebes, and I fancy it must have been all over the known world at the time. The warning stars at Athens were the Pleiades for temples facing the east, and Antares for temples using the western horizon.

But the equinoctial pyramid- and Babylonian-cult in vogue in Egypt in the early dynasties (4000 B.C.), with the warning stars Aldebaran (March) and Vega (September), was also represented in Greece at a much later period.

In Egypt generally, the solstitial worship followed that of the May and equinoctial years. The religion of Thothmes III. and the Rameses was in greatest vogue 2200–1500 B.C.

We find little trace of it in Greece proper, though Mr. Penrose has traced it in Calabria and Pompeii, and in some of the islands.

Because in the first glimpse of the May year we have dates from 3200 B.C. at Thebes, it does not follow that it did not reach Athens before 2000 B.C., because Mr. Penrose found a temple of that date. It is clear, also, that with the possibilities of coastwise traffic as we have found it, it might have easily reached Ireland by then; 2000 B.C., therefore, is a probable date for the May worship to have reached Britain, arguing on general principles; we now know as a matter of fact that it really reached Britain earlier.

May we assume, then, a traffic transferring even astronomer priests from *Egypt* to Britain at that date?

But why not *Greece* to Britain? Because by that time, as we learn from Mr. Penrose, the equinoctial worship from Babylonia had reached Greece as well as the May year from Egypt, and traffic from *Greece* would have brought *both*, but the equinoctial cult did not reach us then; there is no trace of Easter worship in the earliest stone circles.

The solstitial cult was born in Egypt; it is a child of the Nile-rise. I have shown in my "Dawn of Astronomy" that the long series of temples connected with the solstice may have commenced about 3000 B.C.; but for long it was a secondary cult; it was parochial until the twelfth dynasty, say 2300 B.C., Egypt's solstitial "golden age" may be given as 1700 B.C., and her influence abroad was very great, so that much travel, "coastwise" and other, may be anticipated. It is for some centuries after the first date that the introduction of the solstitial worship into Britain may be anticipated. It, for instance, is quite probable that the pioneers of sun worship should have reached Stonehenge in 2000 B.C., but the solstitial worship can only be proved after 1680 B.C.

A paper by Prof. J. Morris Jones on "Pre-Aryan Syntax in Insular Celtic" appears in the "Welsh People," by Rhys and Brynmor-Jones (Fisher Unwin), pp. 617–641. Prof. Jones was led to make the comparisons contained in it by the theory that the long-headed early inhabitants of Britain had migrated into Britain from North Africa. He finds that the syntax of Welsh and Irish differs from that of other Aryan languages in many important respects, *e.g.* the verb is put first in every simple sentence. Prof. Rhys had suggested that these differences represented the persistence in Welsh and Irish of the syntax of a pre-Aryan dialect, and as the anthropologists hold that the pre-Aryan population of these islands came from North Africa, it seemed to Prof. Jones that that was the obvious place to look for the origin of these syntactical peculiarities. He finds the similarities between Old Egyptian and neo-Celtic syntax to be astonishing; he shows that practically all the peculiarities of Welsh and Irish syntax are found in the Hamitic languages.

[1] Westermarck in "Folk-lore." Vol. xxi, p. 27.

This conclusion practically implies that the bulk of the population of these islands, before the arrival of the Celts, spoke dialects allied to those of North Africa. The syntactical peculiarities must have represented the habits of thought of the people, which survived in the Celtic vocabulary imposed upon them.

These conclusions were not known to me when I began to see the necessity of separating the cult of the June from that of the May years, and the identity of the conclusions drawn from astronomical and linguistic data is to me very striking, and also suggests further special inquiries.

The temple conditions in Greece investigated by Mr. Penrose, and on which the above generalisation is based, may be tabulated as follows:—

		Dec.	Day	Year
		° ′		B.C.
May Year.				
Archaic temple of Minerva	Pleiades	+ 7 50	April 20	2020

Britain—Canaan.

Since we have traces of temple worship in Britain 1000 years before the building of Solomon's temple, it may be

useful to see what common practices can be gathered from Semitic and British traditions. We have common to both:—

(1) Worship in high places.
(2) Setting up of stones.
(3) Sacrifices with blood poured on the altar.
(4) Fire worship of Baal or Bel.
(5) Human beings passing through the fire.

The question arises, then, were not the circle builders Semites antedating the Aryans?

The Dolmen Builders.

Another matter of great interest is connected with the erection of dolmens in imitation of the caves first used for Semitic worship. The most philosophical study of this question I have seen[1] certainly suggests that much light may be expected from this source.

NORMAN LOCKYER.

THE SKELETON OF BRONTOSAURUS AND SKULL OF MOROSAURUS.

THE exploration of the American Jurassic by Cope and Marsh for remains of the Sauropoda practically began on an extended scale in 1877. It has been continued by these pioneers and their successors with some interruptions to the present time.

During this period a number of more or less complete skeletons have been found. The first was that of *Camarasaurus supremus*, a sauropod closely related to the Morosaurus of Marsh, found in the Jurassic of Colorado in 1877, and partially described by Cope. It was restored life-size by Ryder on large sheets of linen and exhibited, but never published. The skeleton is now being prepared for mounting in the American Museum of Natural History. The most complete skeleton known of Brontosaurus is the type of *B. excelsus*, Marsh, which was found in the Como Bluffs of Wyoming in 1879, and made the basis of Marsh's restoration of 1883, the first published. This beautiful specimen was unfortunately taken out before the method of removal from the matrix was as effective as it is now. It is, however, capable of being mounted, and will undoubtedly some day be one of the great ornaments of the Yale University Museum, in which it is preserved. In 1897 the American Museum party found the entire hind portion of the skeleton of a Diplodocus also in the rich region of the Como Bluffs. Two years later another skeleton of a Diplodocus, the best yet discovered, was secured by the Carnegie Museum expedition, and forms the chief basis of the great cast recently presented to the British Museum. In 1901 the Field Columbian Museum, of Chicago, secured another fine sauropod skeleton, the basis of the restoration by Dr. E. S. Riggs. It is termed Apatosaurus, a name which Dr. Riggs thinks preoccupies Brontosaurus.

In 1897 the American Museum expedition discovered the skeleton of the Brontosaurus or Apatosaurus represented in the accompanying photograph. It enjoys the distinction of being the first of the Sauropoda to be mounted from the original materials.

The field and museum work on this skeleton occupied the American Museum staff more or less continuously from 1897 to the spring of 1905. In 1898 and 1899 the excavation was carried on, and a little more than two-thirds of the entire skeleton was recovered. In the following year a few more vertebræ were found. The special features are the very large size of the animal, the absence of crushing of the bones, and the completeness of the ribs. The original parts are supplemented by bones and casts or models from other individuals. The chief parts entirely missing are the skull, which was restored partly from an imperfect skull of Brontosaurus, partly from that of the Morosaurus described below, the three anterior cervical vertebræ, the forearms of both sides from the shoulder down, which were restored from the Yale University specimen, the upper portions of the sacrum, the hind-limb of one side, and the terminal portion of the tail. The hind-limb and the tail were completed from other individuals in the American Museum of Natural History.

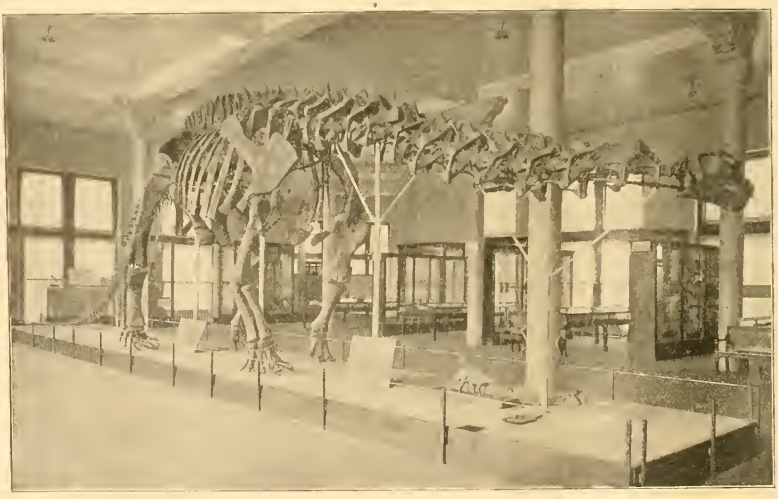

FIG. 1.—Skeleton of the *Brontosaurus excelsus* in the American Museum of Natural History, New York.

The mounting represents the prolonged work of very difficult restoration and the solution of a number of quite new mechanical problems for the support of the immense weight of the fossil skeleton without making the iron and steel work too obtrusive. For this the head preparator, Mr. Adam Hermann, deserves chief credit. A number of new anatomical problems arose, especially as to the position and angulation of the fore-limbs. In this

[1] "The Builders and the Antiquity of our Cornish Dolmens," by Rev. D. Gath Whitley (*Journal R.I. Cornwall*, No. l.).

connection the writer's assistants, Messrs. Matthew and Granger, made a complete restoration of the muscles of the shoulder girdle and of the neck on the basis of dissections of the alligator and lizard. As a result, two important modifications of previous restorations have been made, first, the scapula is considerably more depressed below the level of the back than in previous restorations, thus allowing space for the cartilages between the ribs and coracoid, second, the elbows are considerably everted.

In all previous restorations the manus is represented as provided with a nearly complete series of terminal claws like those of the pes, which lacks the terminal claw only on two digits. Comparison of ten specimens of Sauropoda in various museums has convinced the writer that, *according to present evidence,* in Diplodocus and Brontosaurus there is but one claw in the manus, and that a small one, on the pollex. The arching and elevation of the backbone also come in for considerable modification. Although, as previously supposed by the writer on other grounds, the sacrum was the centre of power and of motion in this great animal, as a result of the depression of the scapula the posterior portion of the neck and middle portion of the back were elevated, and the highest vertebra of the back is not necessarily the spine of the sacrum. Another characteristic of all Sauropoda is the elongation of the neck and the extreme abbreviation of the back, which now in several forms is found to be composed of from ten to eleven vertebræ only. Brontosaurus seems to differ from Diplodocus in the relative abbreviation of length as a whole correlated with the greater massiveness of the skeleton, but especially in the abbreviation of the tail.

	Cervicals	Dorso-lumbars	Sacrals	Caudals
Brontosaurus ...	13 est. ...	10 ...	5-6 ...	49 ± est.
Diplodocus ...	15 ...	11 ...	4-5 ...	35-40

In three specimens of Diplodocus evidence has been found of the consolidation of certain vertebræ of the tail (caudals, 17–18 and 19–21) at the point where they reach the ground. From this it has been inferred that the tail was used partly as a bracing or supporting organ when the anterior half of the body was elevated. There is no evidence of such consolidation in Brontosaurus, and the tail was relatively much shorter. Another difference is that in the tail of Diplodocus the vertebral spines are very lofty, and the transverse processes laterally compressed, indicating that this organ was partly used for propulsion in the water. These characters are much less strongly developed in the massive limbed Brontosaurus.

In this connection we may mention two partly antagonistic theories of the habits of this animal. First, the aquatic theory suggested by Owen in his original study of Cetiosaurus on account of the shape of the caudal vertebræ, and partly supported by Cope on the ground of the extreme lightness of the dorsal vertebræ; this has been more recently supported by Matthew and Gidley on the ground that the limbs were incapable of progression upon land, and were very much more strongly flexed than in any of the restorations of the animal which have been published. The amphibious theory has been partly developed by Cope and the present writer, namely, that the animals spent a considerable part of their life in the water, but were also capable of progression, and even of feeding, upon land; that during the reproductive and hatching period they spent a considerable time on land guarding their nests. A similar theory was advocated by Hatcher in his memoir on Diplodocus.

FIG. 2.—Skull of the *Morosaurus grandis.* 1/7 Natural Size.

The size of the Brontosaurus has been very generally overestimated. The chief measurements of the present skeleton as mounted are :—

	Feet	Inches
Length over all from head to tip of tail ...	66	8
Length of vertebral column	64	4
Length of neck...	16	10
Length of tail	31	4
Length of longest rib...	6	9
Length of hind-limb, including foot ...	10	7
Length of fore-limb, including foot... ...	8	6
Depth of body from lower end of pubis to top of posterior dorsal spine	8	7
Length of head as restored	2	4
Estimated weight of animal when alive ...	38 tons	

As above noted, the long-limbed Diplodocus attained a greater length; the specimen recently presented to the British Museum is 84 feet long. The little known Barosaurus, related to Diplodocus, was of still larger size, and the Brachiosaurus of Riggs had a much greater length of limb, but we have no means of ascertaining its length over all.

It is interesting to compare these measurements with those of a fully grown "sulphur bottom" whale, carefully measured by Mr. F. A. Lucas, and reproduced at the St. Louis Exposition. This animal, a male, measured 74 feet 8 inches from the notch of the flukes to the tip of the nose. The approximate weight of the bones was 17,920 pounds. The entire animal was estimated at not much less than 63 tons.

Our estimate of the weight of Brontosaurus is based on a model by Mr. Charles R. Knight on a one-sixteenth scale, founded upon the actual measurements of the present skeleton. As carefully estimated by Mr. W. K. Gregory

and Prof. William Hallock, of the physical department of Columbia University, the Brontosaurus displaced $34\frac{1}{4}$ tons of water. If the animal was slightly heavier than the water which it displaced, say 10 per cent., it would weigh 38 tons. Prof. Hallock thinks that an estimate of from 35 tons to 40 tons would be very near the truth, even allowing for errors of restoration.

Skull of Morosaurus.

Before the British Association at the Cambridge meeting the remarkable deposit of dinosaur remains known as the "Bone Cabin Quarry" was described. The quarry, which lies about nine miles north of the Como Bluffs, west of the Rockies in south-central Wyoming, is believed to represent a delta or mud and sand bar formation, in which were accumulated more or less complete remains of all the dinosaurs of the period.

FIG. 3.—Model of the Brontosaurus, by Charles R. Knight. Scale of Photo., 1/109. Scale of Model, 308 mm. high, 1/16 Natural Size.

One of the most rare and welcome products of this quarry in the continuous workings which began in 1897 and were recently completed have been the series of skulls, because the skull is the rarest and most fragmentary part of any of the Jurassic dinosaurs. They include one complete and two incomplete skulls of Diplodocus, two complete skulls of the carnivorous Allosaurus, one of Ornitholestes, the supposed bird-catching dinosaur, one of Laosaurus, a primitive iguanodont, one complete skull and portions of two other skulls of Morosaurus. This last is herewith described and illustrated for the first time. It was found at the end of a series of cervical vertebræ by Dr. W. D. Matthew in an extremely crushed condition, and its restoration required great skill and care.

Hitherto our knowledge of the skull of the Sauropoda has been limited to the single complete skull of Diplodocus and to the posterior portion of the cranium of one specimen of Morosaurus, both described by Marsh. These new materials, therefore, greatly expand our knowledge.

The most important point brought out is that all three skulls exhibit a well defined tubular opening on top of the skull at the junction of the parietals and paroccipitals. This foramen is smoothly lined with bone, and leads directly down into the cerebral cavity. It is thus probable that it lodged a large pineal eye, an organ the existence of which was left problematical by Marsh, as shown in the following passage:—

"There is no true pineal foramen, but in the skull here figured (Plate ii.) there is the small unossified tract mentioned above. In one specimen of Morosaurus a similar opening has been observed, but in other Sauropoda the parietal bones, even if thin, are complete." In Marsh's drawing the parietal opening is indicated rather as a fontanelle than as a foramen. While this opening is observed in the form of a bony tube in three skulls, it is of course possible that it was not invariably present in the Sauropoda, and that in some forms the foramen was partially or completely roofed over.

It will be recalled that the skull of Diplodocus has a long snout or antorbital extension supporting a series of slender, pencil-like teeth. The skull of Morosaurus differs widely from this type, first in the highly convex forehead or antorbital region, which is undoubtedly correlated with the presence of the great spoon-shaped cropping teeth, which were comparatively powerful and presented considerable resistance. Above, there are four premaxillary and eight maxillary teeth, decreasing in size as they extend toward the back of the jaw. From twelve to thirteen teeth are preserved in the mandible. The deep, massive proportions of the premaxillaries, maxillaries, and mandibular rami are also mechanically correlated with the insertion and powerful functions of these large teeth. It is evident, however, that as in Diplodocus the animal had no power of masticating its food, and that these anterior teeth served simply for prehensile purposes.

The anterior narial or respiratory openings are very large, facing forward rather than more directly upward, as in Diplodocus, while the openings in front of the orbits are correspondingly reduced. As restored in this specimen, the orbits are of enormous size, but considerable restoration was necessary in the bone surrounding this region, so that the contours of the orbits cannot be certainly ascertained. In the superior aspect of the skull it is evident that the frontal and nasal bones were much longer than in Diplodocus. It is noteworthy that the occiput or back part of the skull has practically the same composition as in the carnivorous Dinosaurs, namely, the parietals hardly enter at all into the top of the cranial roof except to bound the parietal or pineal foramen at the sides; this foramen, which is absent in the carnivorous dinosaurs, is bounded posteriorly by the supraoccipitals. The squamosals form the infralateral portions of the occiput. These resemblances tend, so far as they are of value, to sustain Prof. Seeley's view that the Sauropoda and Theropoda, or carnivorous dinosaurs, are more nearly related to each other (Saurischia, Seeley) than either are to the Predentata (Ornithischia, Seeley); in fact, it is possible to derive the sauropod type from a primitive quadrupedal theropod type, but not to derive either from an iguanodont type.

FIG. 4.—Model of the Diplodocus, by Charles R. Knight. Scale of Photo., 1/105. Scale of Model, 826 mm. long, 1/16 Natural Size.

HENRY FAIRFIELD OSBORN.

American Museum of Natural History, October 5, 1905.

THE PRESENT POSITION OF RADIO-ACTIVITY.[1]

THERE are three fundamental conceptions, the atom, the electron, and the ether. The seventy odd different kinds of atoms known, although fundamentally distinct, form a class to themselves in the complexity of matter, so that any discovery fundamentally affecting one must embrace all. The electron expresses for electricity the same idea as the atom does for any one kind of elementary matter, and may be termed the atom of negative electricity. Only one kind of electricity, and only one kind of electron, is known, and this possesses the same essential properties in all its various manifestations. The ether renders possible "action at a distance," and all actions transmitted through the ether are of essentially the same character and travel at one speed, namely, the speed of light.

The electron, although by origin an electrical conception, is in reality a material conception no less than the atom. At rest an electron is a simple charge—an electrostatic phenomenon. In motion it constitutes a current of electricity—an electromagnetic phenomenon. When an electron moves from rest to speed and back to rest again, the ether through which it moves at first has no magnetic qualities; then it acquires an amount of magnetic energy proportional to the speed of the electron, and then it again loses the same amount. Thus the electron cannot move without the expenditure of energy, and cannot be stopped until it has again given up the same amount. According to Newton's laws of motion, therefore, the electron is essentially a material particle. It possesses inertia, or "apparent mass," but it is not yet known whether it obeys the law of gravity, and possesses gravitational mass.

Since action at a distance travels through the ether at the speed of light, the magnetic field at a point some distance away from the line of motion of an electron cannot instantaneously accommodate itself to a change of motion of the electron, but the disturbance of the magnetic field travels outward from the electron with the speed of light. If the change of motion of the electron is periodic, as in the case of an electron revolving in an orbit within an atom, the disturbance constitutes ordinary light. In the Crookes's tube there is an irregular shower of free-flying independent electrons (kathode rays) upon the anti-kathode. The sudden irregular disturbances in the magnetic field travelling outward from the anti-kathode at the speed of light constitute the X-rays. The Hertz waves, on the other hand, result when electrons are caused to oscillate along paths of metrical rather than molecular dimensions, and their wave-length is measured in metres rather than in molecular diameters.

The apparatus employed largely to generate what are known to medical men as "high-frequency currents" admirably illustrate the inertia of electrons. Such a current will jump an air gap rather than traverse a spiral rod of copper, and will light a high-resistance incandescent lamp "short-circuited" by loop of bar copper. Lightning possesses the same characteristics, as Sir Oliver Lodge was the first to demonstrate.

The question arises whether there are two kinds of inertia, essentially similar, the one "material" and the other electromagnetic. If a sufficient number of electrons could be concentrated within a space of atomic dimensions, the total inertia of the aggregate could be made equal to that of an atom. Unfortunately, we know of no means whereby the mutual repulsions of the electrons could be overcome without introducing the hypothetical positive electron or its equivalent.

The present year is the decennary of M. Henri Becquerel's discovery of the natural radio-activity of matter. Radio-activity has been interpreted as the effect of a process of spontaneous disintegration occurring within the atoms of the radio-element, and already atomic disintegration is recognised as the probable cause of innumerable hitherto isolated phenomena in every branch of knowledge. It is the most fundamental and potent factor of evolution known. The ultimate cause of atomic disintegration, like that of most other common properties of matter, even gravitation, remains quite unknown. The view that radio-activity is the outward and visible sign of deep-seated material change followed from the elucidation of the nature of the emanations, and of the phenomenon of excited or induced activity. It was shown that the emanations and the allied bodies were new forms of matter continuously being *produced* from the radio-elements, and that they were the products of the changing atoms. Rutherford's discovery that the α radiation consisted of radiant particles, and the gradual accumulation of evidence, amounting to-day to practical proof, that the α particles are radiant atoms of the element helium, enabled the whole process to be simply elucidated. A single radiant atom is within the means of detection, for example, by the spinthariscope, whereas a million million atoms is not sufficient to be detected by the most delicate and refined spectroscopic test. The radio-atom suffers successive disintegration, and at each disintegration a single radiant particle is in general expelled. The radium atom successively expels five α particles, so that a residue of atomic weight about 205 should be left if these particles are helium atoms. There is strong indirect evidence for believing that the residue atom is that of lead. In the natural minerals, where the radio-elements occur, are to be found the ultimate products of ages of past accumulation. In the uranium minerals, helium, radium, polonium, and lead have been recognised as the constant companions of the uranium. Direct experiments have established in each case, except lead, the production of these elements during the disintegration. Polonium is the last changing member of the disintegration series, is a higher homologue of tellurium (Marckwald), and is identified with the radium F of Rutherford. The production of lead from polonium has not yet been directly observed, but Boltwood has shown it to be a constant constituent of the uranium minerals.

There is a comprehensiveness and subtlety in the operations of the laws of nature which the most vivid imagination cannot anticipate. The fact that the proportion of radium in any uranium mineral must be constant, being the ratio between the rate of disintegration of radium and that of uranium (or one to a million), cannot fail to have most important bearings. If to-morrow radium could be imported in quantity from outer space, after a few thousand years the quantity in the earth would be no more and no less than at present. By that time the quantity exhibited to-night will have had its day and ceased to be, but if the rest of the mineral from which it was extracted could again be examined a new amount no less than that originally present would be found to have grown in the interval.

How far are we justified in extending these ideas to explain analogous phenomena in the case of the inactive elements? We know that radio-activity is a mere accompaniment by no means essential to the process of atomic disintegration. The evidence available shows clearly that atomic disintegration might be universal and yet beyond the power of direct detection. A discovery fundamentally affecting any one element must embrace the whole class. The internal energy of the atom is merely revealed in radio-activity, in the same way as the internal energy of gun-cotton is revealed only when it explodes. The energy of the disintegration of an element is roughly a million times greater than that of any other change we are acquainted with. The attempt of the alchemist to build up a heavy element like gold from silver was futile, because, even if it could be done, it could not pay. The energy of some hundreds of tons of coal would have to be put into an ounce of silver to convert it into gold; but if gold could be formed from the degradation of a heavier element like lead, the gold would be a mere by-product, and the store of energy liberated simultaneously, however reckoned, would be of far greater value than the gold produced. At present we are totally ignorant of any means of altering or affecting in any way the rate of atomic disintegration proceeding spontaneously, or, in other words, we cannot effect artificial transmutation.

The experimental sciences do not hold out much hope of giving an immediate answer to the question whether atomic disintegration is general, and whether the scarcity or abundance of an element in the earth is a measure of its stability. We are forced back on such indirect evidence as lies ready to our hand. It is possible to obtain such evidence in the field of economics for the element gold,

[1] Abridged from the presidential address delivered to the Röntgen Society on January 4 by Mr. Frederick Soddy.

because gold has been established by long experience to be an excellent if not ideal metal for coinage. Analysing what this means, we find that an extremely complex condition must be satisfied. We are not a stereotyped or stagnant civilisation, and the demand for coinage metal experiences great fluctuations. With the scientific awakening of last century, an enormously increased demand arose in consequence of the rapid extension of commerce. In spite of this it is of the utmost importance that the value of other commodities expressed in terms of that of the coinage-metal must remain fairly constant from year to year, otherwise debtors and creditors might awake to find themselves ruined by some great variation in the value-ratio. Experience shows that this complex condition is, as a matter of fact, nearly fulfilled for the element gold. The first requirement that gold possesses enabling it to fulfil the condition is that it is a technically worthless metal. It possesses usefulness only on account of its value. Platinum, on the other hand, is unsuited for coinage because it possesses value on account of its usefulness. In the latter case the demand increases with fall of price, while in the former it decreases.

The second requirement that has to be satisfied if the value-ratio is to remain constant is that the output of gold should, on the average, bear some fixed ratio to the amount of human endeavour expended in the search. The scarcity must be relative, and some definite number of tons of the auriferous material must on the average be extracted to produce an ounce of the metal. That is to say, the scarcity must be mainly of concentration, as in the case of radium in the uranium minerals. If a technically worthless metal is a member of a disintegration series, so that its concentration in its ores is on the average fixed, it would obey the complex condition required for a coinage metal. So that the argument may be inverted, and indirect evidence obtained that gold is, like radium, a member of a disintegration series. The gold currency cost the world seventy million pounds worth of unproductive labour last year. A sum, which expressed in pounds runs into ten figures, representing the world's accumulated stock of bullion, has been *spent* in the past. To-day it exchanges at its face-value; to-morrow, with the introduction of a less expensive and more scientific system of book-keeping, it will become a mass of technically worthless metal.

This extension of the idea of atomic disintegration shows how powerfully the recent theories are bound in time to affect the life and thought of the community. Those who have grasped their significance know well that nothing appears the same or can again appear quite the same as before. It is not necessary that we should ever approach nearer than at present to the control and application of the new processes and reservoirs of energy. The mere possibility of being able to do so in the future cannot fail to leave its mark. By these discoveries the relation of mankind to nature has undergone a certain change, and man has caught a glimpse of some latent possibilities within his legitimate destiny which cannot be effaced. Energy is the life of the physical universe. You cannot multiply the existing store by a million and leave things as they were. Man, "nature's rebel," as Prof. Ray Lankester has depicted him, left isolated among the forces of nature to work out his own salvation, has had placed before his eyes a new material destiny. So far as physical possibility is concerned, he may one day attain to the power as well as the wish expressed in the quatrain of Omar:—

> "O love! could you and I with fate conspire
> To grasp this sorry scheme of things entire,
> Would not we shatter it to bits—and then
> Re-mould it nearer to the heart's desire!"

MEDICAL INSPECTION AND FEEDING OF CHILDREN IN SCHOOLS.[1]

WE welcome this extension of the inquiry begun in the physical deterioration report, however limited be the terms of reference, viz. (1) to report on what is being done, and with what result, in respect to medical inspection; (2) to inquire into the methods employed, the sums expended, and the relief given by various voluntary agencies for the provision of meals, and to report whether relief of this kind could be better organised without any charge upon the public funds.

(1) Upon the first subject, the results are shown to be most beneficial, the percentage of sufferers being by no means small; thus in defects of vision found in 7 per cent. to 20 per cent. of children examined, headache and apparent dulness often disappear. Twenty per cent. seems a common experience of the incidence of vermin, uncleanliness, and ringworm; here beneficial results have been generally of a marked character, cases being diminished by one-half in nine months in Gloucestershire.

The medical officer of health at Salford demonstrates to the teachers the symptoms to expect in infectious diseases, and the teachers are becoming so skilful in detecting symptoms, and at once excluding all suspected cases, that outbreaks of infectious disease demanding medical inspection are much less frequent. So will necessity for closing the schools diminish.

Diphtheria, it is stated, is now in several areas under such complete control that it can be stopped in a few days. We read in this and similar evidence an urgent call for the extension of medical inspection, and regret that the committee should water their conclusions with a comment that the "results" are to be given as statements of opinion rather than as ascertained facts. The contrary is the case, the facts are ascertained, and if the dozen witnesses coincide, surely we have progressed beyond opinion.

(2) In the second inquiry, in which the committee is to report whether relief can be better organised without any charge upon the public funds, much valuable sociological information has been collected. In many schools 2 per cent. to 5 per cent. of children require this aid, and a meal may cost from a penny to twopence. Seventeen recommendations outline business-like cooperation for charitable relief.

The committee has stated that in the ordinary run of cases which will come up to be dealt with, a woman's opinion upon the need of a household will be more valuable than a man's, and the opinion of two lady witnesses is given that the existing attendance officer is not sufficiently trained, and therefore of no use for the purpose. One would imagine a recommendation would follow that a lady official should be secured for this primary duty of selection of recipients. This omission does not seem explicable on financial grounds, for it might as readily be a charge upon voluntary subscription as upon the public funds. One feels that without such aid the frequent abuse of free meals, as reported in the evidence, is likely to recur.

In this inquiry, all who seek to avoid pauperising parents on the one hand, or the underfeeding of school children on the other, will find much useful information.

[1] Report of Interdepartmental Committee on Medical Inspection and Feeding of Children attending Public Elementary Schools. (Cd. 2779.) Price 1*s.* 3*d.*

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—By the will of the late Sir J. S. Burdon-Sanderson, the laboratory of the pathological department of the University is bequeathed the sum of 2000*l.*, payable within six months of his death, as an endowment to provide for pathological research there, the fund to be vested in the professors for the time being of human anatomy, physiology, and pathology, who are to have absolute discretion as to the application of the fund.

CAMBRIDGE.—Last Sunday completed the fiftieth year during which Dr. Atkinson has presided as Master over the fortunes of Clare College, and the University will on February 1 present him with an address of congratulation similar to that presented to the late Lord Braybrooke two years ago.

Mr. H. O. Jones, of Clare College, has been approved as deputy for the Jacksonian professor of experimental philosophy during the current Lent term.

The following awards to scholarships in mathematics have been made at Queens' College:—N. R. Krishnamma, Merchant Taylors', 45*l.*; C. F. Waterfall, Manchester Grammar School, 45*l.*; A. H. Pinder, Malvern College,

40*l.*; H. C. Bathurst, Dulwich College, 40*l.*; E. T. Lancaster, Exeter School, 30*l.*; G. D. Roechling, Winchester College, 30*l.*

The death is announced, at the age of forty-nine, of Dr. W. R. Harper, president of Chicago University.

The council of the University of Sheffield has appointed Dr. Louis Cobbett professor of pathology, and Mr. L. T. O'Shea professor of applied chemistry in the University.

Sir Michael Foster, K.C.B., F.R.S., will preside at the meeting of the Public Schools Science Masters' Association at Westminster School on Saturday, January 20, in place of the president, Sir Oliver Lodge, F.R.S., who is prevented from being present.

We learn from *Science* that at the recent special session of the State legislature the University of Wisconsin was again authorised to draw its income from the general fund of the State treasury, as according to the new method of appropriating funds for the university by setting aside two-sevenths of a mill on all taxes, the university income fund does not become available until February each year, whereas the university budget has always been estimated on the basis of the fiscal year, which extends from July 1 to June 30 of each year.

On Saturday, January 13, the first annual dinner was held of the past chemical students of the Technical College, Finsbury. Prof. R. Meldola, F.R.S., took the chair, and there were present, in addition to the lecturers and demonstrators of the chemical department, seventy past students of the college. Prof. Meldola referred with pride to the number of past students, who had won distinction in the chemical world, and were gathered around him. Finsbury was one of the earliest technical colleges, and had a record of a quarter of a century's usefulness to the technical industries of the country. Dr. Moody, who proposed "The College," said that this year was a very appropriate one for the first annual dinner, as their head, Prof. Meldola, now held the highest distinction the Chemical Society had to offer, the office of president.

A discussion has been opened in *L'Enseignement mathématique* on the reforms to be accomplished in the teaching of mathematics, and numerous mathematicians have been asked to state their opinions on the conditions that should be satisfied by a complete course of mathematics, theoretical and practical, in institutions of higher grade. The questions are as follows:—What improvements should be effected in the teaching of pure mathematics? What part should be played by higher educational institutions in preparing teachers for secondary schools? And how should mathematical teaching be organised in order that it may respond better than hitherto to the requirements of other branches of pure and applied science? Of those who have already taken part in this referendum, we note the names of Prof. Gino Loria (Genoa), Prof. Emile Borel (Paris), Prof. Jules Andrade (Besançon), Prof. D. E. Smith (Columbia University), Prof. F. Mariotte (Paris).

SOCIETIES AND ACADEMIES.

London.

Royal Microscopical Society, December 20, 1905.—Dr. Dukinfield H. Scott, F.R.S., president, in the chair.—An exhibit consisting of about twenty photographs of diatoms taken by the Zeiss apparatus, designed by Dr. August Köhler, of Jena, for photomicrography with ultra-violet light: Mr. **Rheinberg**. The objective and other lenses used in taking the photographs were made wholly of fused quartz, which rendered possible the utilisation of ultra-violet light having a wave-length of 275 $\mu\mu$ (=275 millionths of a millimetre). The photographs were taken with a 1·7 mm. monochromatic objective of 1·25 N.A., using light from the cadmium spark. The resolving power was therefore as great as would be that of an objective used with ordinary light if it were possible to give it an N.A. of 2·5. There were photographs of *Surirella gemma* and *Amphipleura pellucida*; one of the latter taken with oblique illumination showed the diatom clearly resolved into dots. There were also comparison photographs of the same diatoms, taken with a 2 mm. apochromatic objective of 1·4 N.A. using light from the magnesium spark ($\lambda=383$ $\mu\mu$) giving about the same amplification, viz. about 1800 diameters. The difference in the appearance of the images was very apparent.—A fern fructification from the lower Coal-measures of Shore, Lancashire: D. M. S. **Watson**.

Linnean Society, December 21, 1905.—Mr. C. B. Clarke, F.R.S., vice-president, in the chair.—(1) An aposporous seedling of *Polypodium vulgare*, with a frond bearing a well defined prothallus at the tip. (2) A new case of apospory in *Cystopteris montana*: C. T. **Druery**.—The International Botanical Congress at Vienna in June last: Dr. A. B. **Rendle**. A report was given on the work of the congress, and in particular on the proposals of the conference on botanical nomenclature (see Nature, vol. lxxii., p. 272, 1905).—Cyrtandreæ Malayæ insularis novæ: Dr. F. **Kränzlin**.—On Characeæ from the Cape of Good Hope collected by Major A. H. Wolley-Dod, R.A.: H. and J. **Groves**.

Mathematical Society, January 11.—Prof. Forsyth, president, in the chair.—On the monogeneity of an algebraic function: Dr. H. F. **Baker**.—On the diffraction of sound by large cylinders: J. W. **Nicholson**.—On the expression of the so-called biquaternions and triquaternions by quaternary matrices: J. **Brill**.—Dr. E. W. **Hobson** made an informal communication On the representation of functions of real variables.

Paris.

Academy of Sciences, January 8.—M. Poincaré in the chair.—On a method allowing of the determination of the constant of an absolute electrodynamometer with the aid of an induction phenomenon: G. **Lippmann**. In the determination of the constant of an absolute electrodynamometer, the conditions imposed by the calculation if accuracy of measurement is aimed at are the opposite of the conditions for sensitiveness. In the method proposed in the present paper, the experimental measurement is reduced to finding the equilibrium position of a galvanometer, and measuring either an angle or a length.—On comets, and the curvature of their solar trajectory: Émile **Belot**.—On plane transformations: M. **Hadamard**.—On the non-stationary motion of a fluid ellipsoid of revolution which does not change its figure during the motion: W. **Stekloff**.—On the stability of aëroplanes and the rational construction of supporting planes: Edmond **Seux**.—On the variation of the emission spectra of some electric lamps with temperature: P. **Vaillant**. The lamps studied were the Cooper-Hewitt mercury lamp, the tantalum filament, the Nernst, and the ordinary carbon filament lamps. Figures are given showing the variations in the composition and intensity of the light with the number of watts consumed by each lamp.—On a new type of compound in the group of rare metals: C. **Matignon** and E. **Cazes**. At a high temperature samarium chloride, $SmCl_3$, is slowly reduced in a current of hydrogen to a lower chloride, the analyses agreeing with the formula $SmCl_2$. This lower chloride was obtained by other methods, the complete absence of moisture being the one condition essential. The chlorides of praseodymium and neodymium do not undergo a similar reduction by hydrogen.—The electrolytic preparation of spongy tin: D. **Tommasi**. The electrolytic solution is made up of stannous chloride (10), hydrochloric acid (1), and water (50), and the tin is deposited on a rotating kathode.—On cuprous-silicide: Em. **Vigouroux**. The author has repeated and confirmed his earlier experiments on this subject, and shows that in pure silicides of copper the amount of combined silicon is about 10 per cent.; the crystallised cuprous silicide, Cu_4Si, has been isolated and its principal properties determined.—The reduction of the chlorides of silver and copper by calcium: L. **Hackspill**. The reduction of silver chloride by calcium gives rise to a series of alloys of calcium and silver varying according to the proportion of calcium used. The reduction of cuprous chloride gave similarly a copper-calcium alloy.—Asymmetrical derivatives of 1:6-hexanediol; the diethyl ether and di-iodide of 1:7-heptanediol: R. **Dionneau**.—On the conditions of hydrogenation of some halogen derivatives of fatty hydrocarbons by the metal ammoniums. The preparation of ethylenic and acetylenic hydrocarbons: E. **Chablay**. Sodium, dissolved in liquid ammonia, acts

upon ethylene chloride quantitatively according to the equation $C_2H_4Cl_2+2NH_3.Na=2NaCl+C_2H_4+2NH_3$. The homologues of ethylene bromide give unsaturated hydrocarbons similarly, but there are secondary reactions. With compounds of the type $R.CHCl_2$, the alkali-ammonium reacts differently, giving the paraffin $R.CH_3$.—On the retrogradation and composition of natural starch other than potato starch: Eug. **Roux.**—The action of invertin in a heterogeneous medium: Victor **Henri.**—On solid solutions: Fréd. **Wallerant.**—On the secretory canals in the wood of Dipterocarpus: P. **Guérin.**—On the respiration of the flower: M. **Maige.**—The composition of the fluids which circulate in the plant; variations of nitrogen in the leaves: G. **André.**—On hordenine, a new alkaloid extracted from the germs of barley: E. **Léger.** The alkaloid forms anhydrous crystals of the composition $C_{10}H_{15}NO$. It is a strong tertiary base, forming easily crystallisable salts.—Hordenine, its degree of toxicity and symptoms of poisoning: L. **Camus.** This alkaloid is not highly toxic; death, when it is produced by a large dose, is determined by an arrest of respiration.—On the echinoderms collected by the French Antarctic Expedition under Dr. Charcot: R. **Kœhler.**—On the value of the magnetic elements at the observatory at the Val-Joyeux on January 1: Th. **Moureaux.**—Deep marine currents in the North Atlantic: A. **Chevallier.**

DIARY OF SOCIETIES.

THURSDAY, JANUARY 18.

ROYAL SOCIETY, at 4.30.—The Factors which Determine the Production of Intraocular Fluid: E. E. Henderson and Prof. E. H. Starling, F.R.S.—A Critical Account of some Anomalous Conditions of the Cerebrum in the Human Fœtus: Dr. W. L. H. Duckworth.—A Case of Regeneration in Polychæte Worms: A. T. Watson.—On the Infection, Histology, and Development of the Uredo Stage in certain Uredineæ: I. B. P. Evans.—On the Synapsis in Amphibia: J. E. S. Moore and Miss A. L. Embleton.—On the Constancy of Form among the Synaptic Gemini (Heterotype Chromosomes) in certain Animals: J. E. S. Moore and G. Arnold.—The Growth of the Oocyte in Antedon: a Morphological Study in the Cell Metabolism: G. C. Chubb.—Observations on the Life History of Leucocytes: C. E. Walker.—A Study of the Mechanism of Carbon Assimilation in Green Plants: F. L. Usher and J. H. Priestley.—Note on the Progeny of Chestnut Thoroughbred Horses: W. F. R. Weldon, F.R.S.

CONTENTS.

THURSDAY, JANUARY 25, 1906.

HELIUM IN RELATION TO RADIO-ACTIVE PROCESSES.

Radio-activity. By Prof. E. Rutherford, F.R.S. Second edition. Pp. xiv+580. (Cambridge: The University Press, 1905.) Price 12s. 6d. net.

PROF. RUTHERFORD'S book has no rival as an authoritative exposition of what is known of the properties of radio-active bodies. A very large share of that knowledge is due to the author himself. His amazing activity in this field has excited universal admiration. Scarcely a month has passed for several years without some important contribution from him, or from the pupils whom he has inspired, on this branch of science; and, what is more wonderful still, there has been in all this vast mass of work scarcely a single conclusion which has since been shown to be ill-founded. The general scope of the present work has been noticed in these columns in a review of the first edition. Before passing to the discussion of special points, it is only necessary to say that the second edition fully maintains the reputation of its predecessor for completeness and suggestiveness of treatment.

It is natural to turn eagerly to the paragraph in which Prof. Rutherford discusses what may be called the burning question in radio-activity—Does the α particle consist of an atom of helium? Prof. Rutherford is evidently still inclined to the view that this is the case. He is influenced chiefly by the undoubted fact that helium is a product of the changes occurring in radium, by the approximate agreement in the electrochemical equivalent of the α particles with the value which is considered appropriate to helium atoms, and by the slowness with which the final products of radium are formed. This slowness seems to exclude the possibility that helium, which appears so soon, can be anything but a bye-product.

It is difficult to regard the argument from the electrochemical equivalent as having great weight, for the assumptions which must be made before available measurements can be brought to bear are many and bold.

In the first place, how do we know the electrochemical equivalent of a helium atom? In a case like hydrogen or oxygen we are on safe ground, for experiments on the electrolysis of its compounds enable us to compare the quantity of electricity conveyed with the amount of the element liberated. But no such experiment can be made with helium, for it forms no compounds. It is evident, therefore, that the desired information can only be got by some indirect argument. Unfortunately, the most obvious kind of induction does not lead us to a very satisfactory conclusion. It is found that if we call the charge which a monovalent atom can carry e, then a divalent atom will carry a charge $2e$, a trivalent atom a charge $3e$, and so on. What, then, are we to expect of an atom like helium, which, so far as can be judged from its chemical behaviour and from its position in the periodic classification, has zero valency? Obviously that it should not be able to carry a charge at all in the same sense that the other atoms can do so.

Helium, like other gases, can be ionised by the Röntgen rays, so there is reason to think, from this point of view, that its atom can in some sense be charged.

It has been customary to assume that the appropriate charge to assign to it is that of a monovalent atom. This may be the best view to take provisionally. But further light is much needed.

Again, we have no very direct measurement of the charge carried by an α particle. Prof. Rutherford assumes for that case also the charge characteristic of a monovalent atom, and he has been able to calculate on this assumption the volume of radium emanation and the heating effect of radium. The results in both cases are in satisfactory agreement with experimental data, and Prof. Rutherford is to be congratulated on his remarkable success in showing that such agreement can be obtained. But he would not, in all probability, press the exactness of this agreement as sufficient evidence that the charge of an α particle is exactly that assumed, and not either half or double, for he has had to use many data which cannot but be considered subject to very serious uncertainty. Indeed, the agreement obtained is so good that even if all the premises are correct it must be considered as to some extent fortuitous.

Perhaps the most original chapters in Prof. Rutherford's book are those in which he has so admirably disentangled the complicated series of changes which are involved in the disintegration of radium and its emanation. The idea at one time entertained that radio-activity was determined by high atomic weight must now be abandoned. For it has been made quite clear by these investigations that changes characterised by low radio-activity and slow atomic disintegration are followed by others of far greater rapidity. Radium, in losing atomic weight, turns into the emanation, which, weight for weight, is far more active than its parent.

In the appendix some interesting properties of the α rays are described. This branch of the subject is, however, at present in a very chaotic state, and we shall not discuss it here. One remark may be criticised—nearly the last in the book. Prof. Rutherford thinks that ordinary matter may be emitting as many or more α particles than uranium, if only the velocity of these is less than that minimum velocity which has been found necessary to produce the characteristic phenomena. This is scarcely consistent with the facts if the α particle is a helium atom. For why, in such a case, is helium only found in appreciable quantity in radio-active minerals?

In conclusion, we must once more congratulate Prof. Rutherford on the admirable manner in which he has brought his book up to date, and express a hope that the present edition may have many successors.

R. J. STRUTT.

AN ESSAY TOWARD THE "PRIMA PHILOSOPHIA."

The Metaphysics of Nature. By Carveth Read. Pp. viii+354. (London: A. and C. Black, 1905.) Price 7*s.* 6*d.* net.

CRITICAL philosophy or metaphysics Mr. Read divides into two branches, the metaphysics of nature and science and the metaphysics of ideals. In this work he deals only with the former branch, and only with the most general principles of science. He makes it a rule "not to attempt to solve *a priori* any problem that can only be effectually treated by inductive methods." He discusses in the introduction the meaning of terms like belief and knowledge, reality and truth. Then in Book i., entitled "Canonic," he considers various tests of truth, different forms of scepticism, and the great problem of the relativity of knowledge. Book ii.—"Cosmology"—deals with the doctrine of substance. Book iii.—"Psychology"—deals on the same lines with the subject of experience; while the last book—"The Categories"—discusses relation, the physical categories, and the categories of subjective activity.

The author's beliefs on two of the most general of metaphysical problems may be most concisely stated in his own words. Thus on p. 240 he writes:—

"I am recommending as the most coherent and natural way of thinking, on the whole, this hypothesis that the world is essentially a conscious thing; that in consciousness we have immediate knowledge of Reality, but not of the whole of Being; that the rest of Being is made known to us by phenomena; that it is everywhere conscious, but in various degrees, and that the higher degrees are known to us by the phenomena of organisation."

Again, in dealing with the teleological problem on p. 348:—

"Frankly, I wish it were possible to prove or make credible the teleology of Nature, because we might then follow Aristotle in identifying the End of Nature with the End of Humanity; but I cannot help feeling that the weight of argument is against the doctrine of Final Causation. Like transcendent Being, it remains a merely indicative, orectic category."

The influences to which Mr. Read most readily responds are Hume, Spinoza, to some extent Spencer, and, of course, modern science. The defences of Hume often bring out points too apt to pass unnoticed. Thus Hume's "custom" is described as "intuitive reason in the making." Mr. Read, who has a lurking affection for the sceptical—*e.g.* he thinks that the scepticism of the new academy was superior, even as philosophy, "to the fanatical dogmatism of the Stoics and to the gaseous hypotheses of the Epicureans"—points out the elements of Hume's philosophy which were clearly sceptical, but lays over against them the facts that scepticism was partly a disguise with Hume, and that even Hume puts forward pragmatism as the natural remedy for scepticism.

Hume's great follower or controverter, Kant, receives interesting treatment. Mr. Read refuses to join in the "hysterical outcry" against the thing-in-itself; but he finds abundant cause for complaint in Kant's mythological method of arguing from the unity of consciousness to a substance, a "thing" that "forms an idea." Kant's famous statement is quoted:—"If there is no *Urwesen* distinct from the world, if the world is without a beginning and therefore without a Creator, if the will is not free, then moral ideals and principles lose all their validity"; and Mr. Read adds, "It is impossible to find in literature a more desperate sentence than this, or a more false."

One welcomes the clear distinctions drawn in the introduction, chapter ii., between empirical, physical, transcendent, and noumenal reality; the defence, too, of much-abused eclecticism on the ground that after all the great systems in philosophy are themselves patchworks. And unless one is wedded to the theory that philosophy must be dull if it is to be sound, one rejoices in the good sayings—often as sensible as they are pungent—with which the book abounds, such as—"Future generations may have reason to thank those who left them something to do, more than those who anticipated everything," or the description of Hegel's rationalism as only an unintelligent empiricism. But no short notice like this can do justice to the closeness of the argument, the soundness and comprehensiveness of a book which must be ranked among the most important of recent years.

There are one or two animalcules in the ointment. Locke's great work is referred to as "Essays of Human Understanding"; and in talking of Hume's "Treatise" the author gives references to the parts only, forgetting that there are in it books divided into parts. Words like *verbile, questionnaire, glissaded,* do not find favour with all readers. An index might well have been provided, but its absence finds much compensation in an excellent table of contents.

MATHEMATICS FOR THE LABORATORY.

Higher Mathematics for Students of Chemistry and Physics, with Special Reference to Practical Work. By Dr. J. W. Mellor. Second edition, enlarged. Pp. xxi+631. (London: Longmans, Green and Co., 1905.) Price 15*s.* net.

THIS is the second edition of a book which from the first was recognised as filling a place of its own in our mathematical literature. It is essentially a book for the student of chemistry, for whom a smattering of mathematics used to be supposed to be sufficient. The result was that our college curricula made no provision for training chemists in the mysteries of the calculus, at least no compulsory provision. When at length the eager student came in touch with modern work, say, on the velocities of reactions, or on thermodynamic developments in general, he encountered mathematical methods and even notations quite unfamiliar to him. What was he to do? Go and quaff the heavenly nectar provided by Williamson or Lamb? But this, we learn from Dr. Mellor's preface, brought perplexity rather than clearness of vision. What the student of chemistry wanted was a working knowledge of the methods of the differential and integral calculus, with a minimum

of theory and demonstration. The student of physics is somewhat differently circumstanced. From time immemorial physical research and mathematical methods have been more or less closely associated, and every student of physics knew that a certain knowledge of higher mathematics was demanded of him. Yet complaints have been heard even from him that the mathematical courses in our colleges lacked a certain flavour of the real, and were not particularly suited to his needs. It has often been said that there is no royal road to mathematical knowledge. To quote Dr. Mellor himself, a certain amount of drudgery is necessary in some stages. But some roads are easier than others; and in this book chemical and physical problems are introduced, like rest houses along a weary way, to cheer the flagging traveller. Here he finds familiar food for his mind. To change the metaphor, the student is given a new weapon, and at the same time is taught how to use it on material already his.

To what extent the reader, otherwise ignorant of the principles of the differential calculus, will be able to appreciate the first chapter, experience alone can tell. The introduction of sections on proportionality and logarithms in the middle of the discussion of differentiation does not strike one favourably. The author's reference to this in the preface may, however, be accepted as sufficient excuse.

The new edition is fundamentally the same work as the old, but about a fifth more bulky. The increase in size is due partly to a more sparing use of small type, but chiefly to the introduction of new matter. There is also a good deal of re-arrangement of individual sections, such, for example, as the carrying forward of the paragraphs on the Gamma and elliptic functions from chapter iv. (the integral calculus) to chapter vii. (how to solve differential equations). From a physical point of view this is undoubtedly the better arrangement; and there is a further improvement which deserves notice, namely, the leading up to each of these functions by the discussion of a comparatively simple dynamical problem. The most obvious addition is the new chapter on the calculus of variations, in which brachistochrones and isoperimetrical problems are touched upon. Probably the main service rendered by this chapter will be to enlarge the outlook of the student. The class of readers for whom the book is ostensibly written will hardly ever be called upon to apply the calculus of variations, and if they should be they would find the discussion too meagre for them to make effectual use of it; but it is a real service to open a man's mind to the things which lie beyond the immediate purpose of his life. The still too common utilitarian idea that the practical man should be taught just as much mathematics as we know to be necessary for his immediate needs is an idea which cannot be too strenuously contested. The truth is, we never know what will be needed before the year is out. The chemist of the last generation would as soon have thought of studying the properties of Theta functions as of familiarising himself with the modes of solution of the simpler differential equations, or even with the meaning of a differential coefficient; but that attitude of mind is impossible now. The theoretical chemist of the rising generation must know his mathematics, and we are convinced that many will bless Dr. Mellor for providing them with an eminently readable and thoroughly practical treatise.

Throughout the book there are many historic notes which are always interesting in their way. It will not, then, be thought amiss to direct attention to the section on pp. 59 and 60, and to ask why writers are so slow to do Newton justice in regard to his so-called law of cooling. It is now six years since Prof. Crichton Mitchell, in a paper on the convection of heat by air currents (*Trans. R.S.E.*, vol. xl. p. 39), pointed out, what seems to have escaped the notice of every commentator except Fourier, that Newton deliberately placed his cooling body "non in aere tranquillo, sed in vento uniformiter spirante." Dulong and Petit, therefore, and all their copiers, including Dr. Mellor himself, are not giving "a typical example of the way in which the logical deductions of an hypothesis are tested" when they try to apply Newton's law to a body cooling in tranquil air. Crichton Mitchell showed that when Newton's conditions were realised Newton's law held with wonderful accuracy over a considerable range of temperature differences.

C. G. K.

PLANT DISEASES.

Minnesota Plant Diseases. By Dr. E. M. Freeman. Pp. xiii+432. (St. Paul, Minnesota: The Pioneer Press.)

THIS publication is issued for "the people of Minnesota" by authority of the university of that State. It may have special reference to a particular State, but it is quite evident, from a perusal of its pages, that the book will be of service wherever plants are cultivated. The author takes a broad view of his subject, and rightly considers the prevention of disease as a more important matter, from the point of view of the cultivator, than the application of remedies. "Agriculture," says he, "really resolves itself into one great problem, the prevention of plant-disease." Keep the "patient" in good health by careful attention to his physiological requirements, by cleanliness and by strict compliance with the teachings of hygiene. Much more good will ensue from these measures than from the use of insecticides or anti-fungus sprays. A knowledge of the life-history of the plant, as well as a corresponding familiarity with the mode of life of the hostile insect or fungus, is, indeed, essential, but unless combined with the faculty of turning that knowledge to account, the information is, practically speaking, of no value.

The first question that is asked when a diseased specimen is submitted is, "What is the matter with this plant?" The next, and in the view of the questioner the most important, is, "What am I to do to get rid of the disease?" Not one in a hundred cucumber-growers, cultivators of the vine or other crops, asks a question as to the methods of preven-

tion; the ninety and nine ask for a "cure." Yet whilst prevention is often within reach, cure, in the proper sense of the word, is frequently impossible. The diagnosis of the disease must be left to the skilled expert, the means of prevention should be known to all intelligent cultivators, the remedy may be prescribed by the plant-doctor, whilst the "cure," which often means the bonfire, may be entrusted to the labourer.

Another point which cannot be overlooked in considering the prevention of epidemic diseases is the necessity for concerted action. If one cultivator is alive to the exigencies of the case his labour is often vain if his neighbour be slovenly and apathetic.

The book before us is divided into two parts, the first dealing with the fungi which are injurious to plants generally, the second with the specific diseases of Minnesota vegetation. The account of the nature, mode of growth, and habits of fungi is written clearly and in a style readily comprehensible by the reader of average intelligence. It forms, indeed, an excellent introduction to the study of fungi.

A separate chapter is given to the history of the bacteria which presents in a concise form many details of the utmost importance to cultivators. After these generalities attention is directed to the fungous diseases most prevalent in Minnesota. To these we need not here specially refer, nor to the sections on fungicides and spraying apparatus. We can only add that the book is well illustrated and provided with a copious index. We commend it to the notice of all who are interested in plant-diseases, and especially to foresters and cultivators of field or garden plants.

OUR BOOK SHELF.

Mesure et Développement de l'Audition. By Dr. Marage. Pp. 119. (Paris, 1905.)

THIS small volume by Dr. Marage is of scientific value inasmuch as it contains an account of a method by which acuteness of hearing can be measured, and by which any degree of deafness can also be stated with accuracy. Aurists for many years have made use of the ticking of a watch, the sound of a tuning-fork, or a percussion sound as a source of sound, and they state the degree of deafness by a measurement of the distance at which the patient can hear the sound as compared with the efficiency of a normal ear. The best of all acoumeters, no doubt, is the human voice, as it gives sounds to which the ear is adapted; but no two human voices are alike, in consequence of the variations in quality caused by the vocal resonating cavities.

Dr. Marage, however, has invented a siren which is furnished with resonating masks (casts of the vocal cavities as adapted for the vowels OU, O, A, E, and I). This apparatus utters these vocal tones with singular purity. The form of the mask, and especially that of the oral opening in each case, suppresses most, if not all, of the overtones for each vowel, and the laryngeal vowel tone (produced by the siren) is alone sounded. Further, he has shown that the intensity of the sound of this instrument, as measured by a special water-manometer, is proportional to the pressure of the air which traverses the apparatus. The siren can be adjusted for any vowel, and the apparatus is always at the same distance from the ear. The measurement of the auditive acuity is given in the number of millimetres of water shown in the manometer when the sound of the particular vowel is heard. Thus any vowel sound is heard with a pressure of 1 mm. by a normal ear; if the pressure must be raised to 40 mm. before the sound is heard the auditive acuity is 1/40, if at 60 mm. 1/60, if at 200 mm. 1/200, and so on.

Dr. Marage also shows an ingenious method of recording on a chart the degree of acuity for each vowel, always in mm. of water, and if the points for the various vowels are joined a curve is produced. The form of this curve varies with different pathological conditions of the middle and internal ear, so that after the patient's ear has been tested for the vowel tones by the siren, and the curves have been plotted out, the form of the curve is of value in diagnosis. Lastly, Marage uses the siren to massage the drum-head and chain of bones by giving to the ear for a certain time, say a daily massage of ten minutes, using the vowel tones of the instrument, and he asserts, and shows by charts, that in a large percentage of cases of many forms of ear trouble, and in some cases even of deaf mutism, there is benefit derived from the massage treatment. These results cannot be criticised in a scientific journal, as they pertain more to the region of the practical aurist, but there can be no doubt of the value of the method of Marage as a method of accurately determining acuteness of hearing. JOHN G. MCKENDRICK.

American Insects. By Vernon L. Kellogg. Pp. vi+674; 812 illustrations and 13 plates. (New York: Holt and Co.; Westminster: A. Constable and Co., Ltd., 1905.) Price 21s. net.

THIS work is intended as an introduction to North American entomology. It consists of a systematic review of the various orders of insects met with in America north of Mexico, and of introductory and supplementary chapters dealing with special subjects. The three introductory chapters on structure, physiology, development and classification are well done, a great deal of information being condensed in these 50 or 60 pages.

The supplementary chapters are, however, the best part of the book. They are (1) insects and flowers; (2) colour and pattern and their uses; (3) insects and disease. These subjects are treated in an intelligent manner, with an absence of dogmatism that is very commendable.

In some parts of the work the author is a little more rash. Thus he concludes his account of the slave-making ant, Polyergus, with the dictum "specialization is leading Polyergus to its end!" Whether this is the case must be left to the future to decide. It would have been simpler to say that Polyergus has mandibles unsuited for industrial purposes, and correlatively possesses slave-making habits that do not appear to be very successful.

Of the systematic part of the work we cannot speak so highly; this is chiefly due, it is only fair to say, to inadequate space. There are, as the author says, 10,000 kinds of beetles in North America, as against 1000 kinds of birds. It is small wonder that the attempt to condense an account of 10,000 species and their habits and life-histories into 54 pages does not leave a satisfactory impression. The extensive orders Coleoptera and Diptera have suffered most from their abbreviation. The Coleopterous portion, moreover, has not been adequately revised, the larva of a Longicorn beetle being figured as a type of the larvæ of the Buprestidæ.

Notwithstanding these drawbacks, the work is probably the best that exists for anyone desiring an introductory work on North American insects compressed into a single volume. D. S.

First Steps in Quantitative Analysis. By J. C. Gregory. Pp. vi+136. (London: Edward Arnold, 1905.) Price 2s. 6d.

IN this little book the author has aimed at "providing a grounding in the fundamental principles of quantitative analysis. It includes the use of the fundamental volumetric solutions and several gravimetric estimations." Of the existence of a considerable class of students whose requirements would be satisfied by the scope of the work there can be little doubt, and a small laboratory manual dealing with a few typical gravimetric and volumetric processes cannot be regarded as superfluous. The author's choice of material leaves little to be desired, but exception may be taken to matters of detail. The percentage strength of a solution is defined as the number of grams of substance in one hundred cubic centimetres, a definition which is scarcely acceptable to the majority of chemists. The first alternative method described on p. 64 for the preparation of a normal sodium hydroxide solution may perhaps give results accurate to 1 per cent., but is scarcely consistent with the employment of a multiplying factor containing five significant figures. Such inconsistency in the use of significant figures is not infrequent, and detracts considerably from the value of the book. On p. 67 it is stated that "the specific gravity of strong hydrochloric acid is 1·16 and the liquid contains 31·79 per cent. by weight of hydrogen chloride"—the temperature is apparently of no consequence whatever. A brief consideration of the theoretical side of the methods and operations involved would have made the book considerably more useful as an introduction to quantitative analysis.

H. M. D.

Man: an Introduction to Anthropology. By Dr. W. E. Rotzell. Second edition. Pp. 186. (Philadelphia: J. J. McVey, 1905.)

THE author of this book is a lecturer on botany and zoology in Philadelphia, but the systematic details he adopts are those of "Prof. Alexander Macalister, of the University of Dublin, and of the late Prof. H. Alleyne Nicholson, of the University of Toronto," so no one can accuse him of being up to date in his own subject. "Anthropology," he informs us, "seems to be, unfortunately, one of those subjects about which the vast majority of persons know very little," and with a zeal which far exceeds his knowledge he attempts to remedy this defect; but it is evident his information is second-hand, imperfectly comprehended, and ill-digested.

The following quotations will serve to substantiate this criticism:—"The North Mediterranean branch (of the White or European Race) comprises the Basques, the Aryans, and the Caucasic peoples." "The Indic group (of the Aryans) inhabit an extensive region of Southern Asia. At present there are many different tribes and castes inhabiting the great Indian peninsula, the forms of speech spoken by them presenting numerous diversities"; except for a word or two about Sanskrit and Buddhism, this is all that is given on the ethnology of India. In his final chapter, on the development of culture, Dr. Rotzell puts forward the view that the blazing of trees was the beginning of writing.

Elementary Algebra. By W. G. Borchardt. Pp. vii+492+lxiii. (London: Rivingtons, 1905.) Price 4s. 6d.

THE arrangement of the subject adopted in this work differs from that adopted in many other works, simplicity and ease for the beginner being the chief object. The fundamental operations (addition, subtraction, multiplication) are illustrated graphically on squared paper, and the solution of simple equations is given immediately afterwards, such subjects as fractions, highest common factor, and lowest common multiple being postponed; in fact, fractions are left until the beginner has acquired a considerable skill in the solution of equations. Great use is made of graphic illustration, and by means of it many difficulties are removed from the path of the beginner.

The plan of the book leaves nothing to be desired on the score of simplicity; it is about the most simple work that we have seen. The advanced part of the book may be said to begin with chapter xxxii., which treats of the theory of indeterminate equations. The general theory of quadratics follows, as well as the discussion of progressions, binomial and multinomial theorems, &c. Every branch is illustrated by a large collection of examples, with answers.

Illustriertes Handbuch der Laubholzkunde. Part iv. By C. K. Schneider. Pp. 449–592. (Jena: G. Fischer, 1905.) Price 4 marks.

A PORTION of the Rosaceæ is treated in this part, beginning with Spiræa, passing from the Spiræaceæ to the Rosaceæ and then to Prunus. Why the author distinguishes Spiræaceæ and Drupaceæ as orders is not obvious, but this causes no inconvenience to anyone using the book for practical purposes; and in this connection it should be stated that the analytical tables for running down the genera are made as concise as possible, and that cross references are inserted in the margin to facilitate the comparison of subdivisions.

The part includes three large genera, Spiræa, Rubus, and Rosa; while examining the Spiræas in the Boissier herbarium, Mr. Schneider came across several specimens, chiefly Asiatic, that he regards and has named as new species. In the case of Rubus, a selection has been made of European types and a number of foreign species that may be found suitable for introduction into Europe. Undoubtedly the most interesting portion is that devoted to the roses; the treatment follows very closely the arrangement given by Keller in Ascherson and Graebner's synopsis, but Keller's subsections are classed as sections, a system that is of practical convenience, although it tends to magnify the importance of the subsections. Amongst the changes noted, Schneider follows Keller in superseding *Rosa indica*, L., by *Rosa chinensis*, Jacq., and *Rosa damascena*, Mill, perhaps on account of its antiquity, is numbered as a species.

Esquisse d'une Théorie biologique du Sommeil. By Dr. Ed. Claparède. Extrait des *Archives de Psychologie,* T. iv. Pp. 114. (Genève: H. Kundig, 1905.) Price 3.50 francs.

IN this essay, the contents of which have appeared in certain journals, the author first examines the various theories which have been propounded to explain the occurrence of sleep, and having found these wanting proceeds to formulate a theory of his own.

The various theories of sleep are first classified and discussed, and the difficulties in accepting them stated. All the common theories regard sleep as a cessation of function in the organism, a negative or passive state or phase. The author, however, regards sleep as an active state, a defensive mechanism of the nature of a reflex action, an instinct which has for its object the precipitation of the organism into a condition of inertia whereby exhaustion is prevented. We therefore sleep, not because we are exhausted or asphyxiated or auto-intoxicated, but in order to ward off such effects, and many interesting facts are quoted in support of this hypothesis. The essay deals in a concise and interesting manner with the whole subject of sleep, and is well worthy of perusal.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Percy Sladen Expedition in H.M.S. "Sealark" to the Indian Ocean. The Seychelles Archipelago.[1]

AFTER leaving the *Sealark* and dispatching our collections home, Mr. Forster Cooper and I spent seven weeks in exploring the Seychelles Archipelago as thoroughly as possible, dividing our time between Praslin and Mahé as centres. We camped for eighteen days on the former island, and then separated, Mr. Cooper being responsible for Silhouette Island, the fauna of which appeared to be almost unknown, while I visited various parts of Mahé and examined its reefs and neighbouring islets. Unfortunately the weather had been exceedingly dry, and continued to be so during the first half of our stay, while it was correspondingly wet during the second half. As a result, land collecting was at all times extremely laborious, and insects were throughout found to be scarce, both in species and number. Other groups of land animals we believe to have been fairly thoroughly collected.

The Seychelles Archipelago comprises a number of islands arising on a submarine bank, which extends in a more or less east and west direction, about 190 miles long by 100 miles broad (Fig. 1). It was fairly regular in contour save to the south-east, where a horn stretches out for some distance along the line towards Mauritius. Separated from this same projection by deeper water are three similar but smaller banks, of which that of Coetivy alone has land, and in correspondence there is to the south-west the Amirante Bank with its little group of islands.

The Seychelles Bank itself has an average depth of 30 fathoms, and our soundings off it to the north-west, east, and south show that it has a contour similar to those of typical coral reefs and banks. An outer rim is indicated along the whole of its north-western half by a series of shallower soundings, but to the south-east the depth does not markedly shoal (Fig. 1). It has two typical surface-reefs with coral islets to the north, Bird and Dennis, but elsewhere the rim is generally covered by at least 7 fathoms of water. Between these two islands, and to the west of Bird, the character of the bottom is somewhat similar to what we found at the edges of the submerged Saya de Malha and Nazareth Banks, and indicates the upgrowth of a rim. The fauna was more varied, but the bottom was less covered by nullipores and corals, and a few green algæ were abundant. All sedentary organisms were covered with dirt and unhealthy between Bird and Dennis Islands, where there would appear to be a natural outfall for the tidal and other currents. In this position there is certainly no upgrowth of the rim, while elsewhere it must be exceedingly slow. The bottom within the rim is sand, muddy sand, or mud, the latter held together by the roots of algæ. Strong currents sweep across it, and even during our visit, between the two trades in dead calm weather, the sea-water was always cloudy, so that, except in favoured spots, corals could scarcely grow up into reefs.

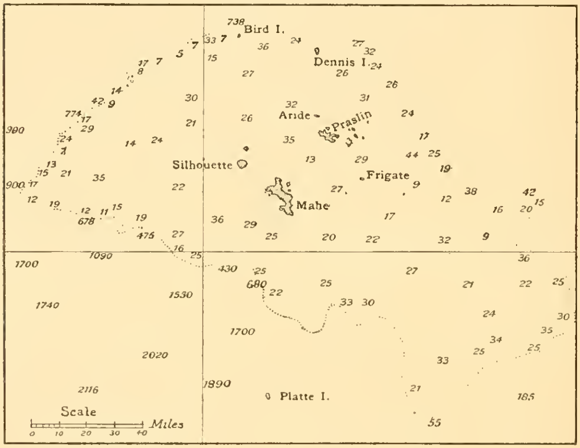

FIG. 1.—Seychelles Bank showing the 100-fathom line.

The islands of the Seychelles naturally divide themselves into two groups to the west and east, with Mahé and Praslin as centres (Fig. 2). The former comprises Mahé, Silhouette, and North, with a series of small islets around the first, outlying buttresses and peaks of the same, with only a few fathoms of water between. Praslin also is similarly surrounded by a series of tiny islets and rocks, but in addition there are eleven other islands in its group (of which we visited five), separated by considerable channels. Mahé and Silhouette attain heights respectively of 2993 feet and 2467 feet, but Praslin and the eastern islands do not exceed 1270 feet. All islands were found to be formed of similar, coarse granites (or granulitic quartzes), with narrow, vertically extending dykes of finer grained black rock, apparently a variety of granite, along which the mountain streams have invariably cut their courses. In addition, many of the islands have against their coasts, in bays and suitable situations, flats of sand, largely coraliferous. Some of these have doubtless been formed by a washing up of sand from the sea, and some are partially at least of delta formation, but in places there is evidence of a recent elevation of more than 30 feet. On the island of Silhouette, Mr. Cooper in five situations found masses of coral rock, cemented on to the granite, at various heights between 15 feet and 30 feet above the low-tide level, and around the coasts of Mahé and its smaller islets there is evidence of a similar upheaval. Besides this, there are indications (particularly in Mahé) of an ancient elevation of upwards of 200 feet. Definite rocks belonging to it do not, so far as I could find, still exist. Marine action prior to its occurrence perhaps accounts for the almost continuous line of precipices, which at various distances from the present coast extends along the eastern or windward side of Mahé. The question, however, requires further investigation. In any case, the deep cañons of many of the mountain brooks, and the very extensive weathering of the granites, indicate the not inconsiderable antiquity of the land as such.

Barrier reefs nowhere exist around the islands of the Seychelles Group, and fringing reefs only in certain somewhat protected situations (Fig. 3). Mahé Island extends more or less north and south, with two conspicuous points to the west. A fairly continuous reef lies along its east side, but there is no reef off its north and south points, and reefs only occur in the bays of its western side. Silhouette is a round island with practically no reef, while Praslin has reefs in its bays alone. La Digne, Curieuse, and the smaller islands have merely patches of reef. On examining into the causes of this we found a luxuriance of coral growth even off the points of the islands, but practically a complete absence of nullipores. Indeed, these calcareous algæ are essential in the Indian Ocean for the consolidation of corals into true reefs. Where fringing flats actually do occur, they would appear generally to consist of a basis

[1] For earlier reports see NATURE, April 13, August 10, October 5, November 9, and December 21, 1905.

of granitic rock with quite a sparse covering of calcareous matter, or to be a filling in with the remains of some of the reef organisms between masses or islets of granite and the land. The reef in the large bay to the north of

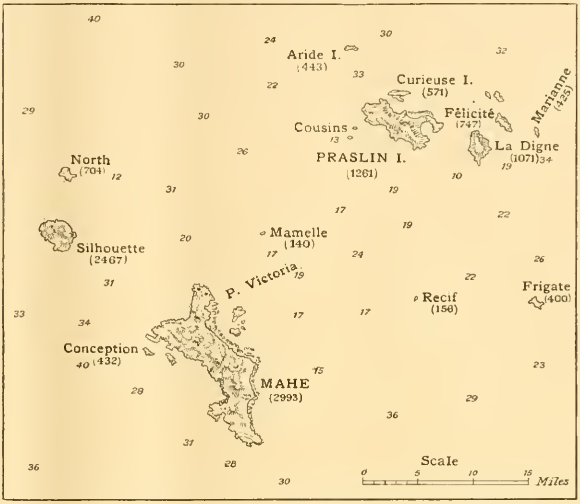

Fig. 2.—Islands of the Seychelles Group with heights in feet and soundings in fathoms.

Praslin, extending along the coast for $1\frac{1}{2}$ miles between two points, is a good instance of this, one islet and three series of granite masses lying at almost equal intervals imbedded in its seaward edge. The boat passages through the reefs are in most situations mere outfalls for the tide, and show no connection with the fresh-water streams off the land. Finally, it is interesting to note that the actual surfaces of the flats are covered with a far greater variety of large seaweeds than we found in any of the purely coral groups we visited in the *Sealark*.

The land animals necessarily to a large extent depend on the plants, and I considered it inadvisable to attempt their complete collection in the limited time at our disposal save in the indigenous jungle. Small mangrove swamps occur on the sea-shore, but behind these the land has been almost completely cleared for the cultivation of cotton, coffee, cassava, cocoa, and vanilla to a height of 1500 feet. Below this there are only a few isolated endemic trees, and above there are in patches in the jungles large numbers of oranges, limes, citrons, and cinnamons, with an undergrowth of the Mauritius raspberry, all introduced plants. Indeed, there are, except in Silhouette, only a few summits and precipitous slopes which have not been at one time or another completely planted, and it seems possible that even these may be destroyed within a few years for the cultivation of various rubbers. Such jungles as now remain consist mainly of palms (Roscheria, Stevensonia, Nephrosperma, Verschaffeltia), various screw pines (Pandanus), Dracæna, and the bois rouge (Wormia), with bare ground beneath covered by their strong leaves, clumps only of Curculigo. Open spots, however, have a dense undergrowth of ferns, Lycopodia, Selaginellæ, Psilota, and mosses, which also cover the lower parts of the trees. In effect, it is a typical, tropical, moist forest undergrowth, noticeable mainly for the comparative absence of climbing plants and herbaceous dicotyledons, and for the fact that nearly all the larger trees are peculiar Seychelles species, and often genera. Most of the giant trees (Maba, Stadtmannia, Afzelia, Campnosperma, &c.), have been singled out and cut, but bare stems of capucin (*Northea seychellarum*) stand up everywhere above the foliage. The destruction of the latter, which probably will shortly be complete, we discovered to be due to a green beetle, which deposits its eggs singly in the new leaf-buds, the resulting maggot consuming all their softer parts.

The most interesting feature in the botany was the sharp distinction of the cotyledonous plants into three classes, the calciphilous, the siliciphilous, and the indifferents, the latter forming a smaller percentage of the whole than either of the other two. The calciphilous species are practically the same as we found on all the coral islands we visited, and are scarcely more numerous. This group of plants was, I consider, ocean-carried, the Seychelles being in respect to it as oceanic as any island of the Chagos Archipelago. Moreover, of the other trees many seemed to possess seeds, which could have been brought by currents, &c., to the islands. The finest individual species of tree was the coco-de-mer, or double coconut (*Lodoicea seychellarum*), which is peculiar to

FIG. 3.—Fringing Reef with boat passage to the south-east of Mahé Island, looking south

Praslin. Its palms are either male or female, and our examination of more than 300 of its nuts showed that they are of two distinct, structurally different forms in approximately equal proportions, both kinds growing on the same female tree. The case is, so far as I know, unique.

Of the land animals we did not attempt to collect the birds, as they were already sufficiently known. Moreover, most of the peculiar Seychelles species would seem to have been nearly, if not entirely, destroyed by paid collectors. The Government of the Seychelles has, however, promised an ordinance to hinder further destruction. The introduced birds do not belong to the jungle, where, indeed, land birds are seldom seen. Mammals are represented by rats, mice, and bats, and the tenrec runs wild everywhere. Of reptiles we obtained about eleven species of lizards and three snakes. The crocodile would once seem to have been a regular inhabitant, but the last was killed about seventy years ago. Three of the apparently four species of frogs occur at any elevation, but the fourth is peculiar to the high jungles. Cœcilians are numerous, the one genus being an earth burrower, and the other lying under damp leaves in the jungles. Mollusca were represented among the indigenous vegetation by twenty-five to thirty species, including two slugs, and we obtained a fair variety of insects and arachnids. Isopods were numerous everywhere, but centipedes and millipedes were scarce on the high lands, and seemed to consist of species peculiar to them. We carefully searched for Peripatus, but do not think it exists in the archipelago. Land worms were scarce; one species was peculiar in living within the bases of the screw pine leaves, even 40 feet to 50 feet above the ground. We obtained no land leeches or Turbellarians, but found two species of Nemerteans at about 2000 feet.

The fresh-waters consist of certain pools near the sea and a large number of tiny mountain streams, which become roaring torrents in the wet season, but never dry up. In a pool at La Digne we obtained one tortoise with hinged plastron, and in the streams there were four species of fish. The Crustacea comprise at least two species of prawn and a crab, all living up to more than 2000 feet. The Mollusca number only three, and for the rest there were the usual genera of fresh-water insects, &c.

The number of species of land and fresh-water animals would on the whole appear to be singularly few, and individuals were, with a few exceptions, by no means abundant. Their small variety may be due to the comparatively few plants which grow in the islands, but one is inclined to question the former connection of the group with any larger land mass. In any case, our work has made certain that the archipelago has been sufficiently collected for a thorough examination into this question from a biological point of view. It is our opinion, however, that such a research should include both animals and plants considered together. In any case, the Seychelles is the continuation of a broken line extending north from Madagascar, and its rock would seem to be similar to that which forms the great central plateau of that island.

Since I returned to England I have received a letter from Commander Boyle Somerville giving the soundings obtained by H.M.S. *Sealark* on her return to Ceylon from the Seychelles. He has confirmed by additional soundings the complete separation of the 2000-fathom lines of the Chagos, Maldive, and Seychelles groups. I have also heard from Mr. D. Matthews that he has obtained about 1000 samples of sea-water from the Indian Ocean during the last nine months, and analysed about 700. Mr. Bainbrigge Fletcher, H.M.S. *Sealark*, reports that a considerable number of the Chagos Lepidoptera appear to be new species or varieties.

What Causes the Destructive Effects of Lightning?

I ENCLOSE a cutting from the *Hampstead and Highgate Express* (January 20) containing an epitome of a lecture which I lately gave at the local scientific society on a case of death by lightning which occurred on the Heath in the month of July last.

I discussed, amongst other matters, the question as to how the more destructive effects of lightning were produced, and now my object in writing to NATURE is to ask you, Sir, or any of your readers, if you can inform me whether this question has been solved in any probable manner. In the case of the death of an animal from lightning I think we may safely rest on the word electricity as sufficient, for it is not difficult to understand how this form of energy when let loose in the organism of an animal should not only disturb the equilibrium of the machinery, but actually stop it. But the word electricity does not seem sufficient to account for the more destructive effects produced by lightning, which closely resemble those which arise from other well known allied forces. Heat certainly is produced, as we see by the burning of the flesh and by its effects on metals, but as regards the destruction of trees, buildings, and other imperfect conducting substances, the forces seem to be of an explosive character, as are mentioned in the accompanying extract from my lecture.

"The subject which was of most interest to the lecturer was the nature of the destructive agency of the lightning flash, and the present fatal case he thought threw a considerable light upon it. Of course, there was no difficulty in understanding how an electric shock can kill an animal suddenly by bringing the machinery to a stop, when it is considered how fearfully and wonderfully we are made, and that vital processes are at work in every part, when a violent electric shock comes and arrests all these at once. But it is not so easy to perceive how all the more marked and mechanically destructive processes occur, such as the splitting of the timbers in the hut or tearing off the clothes. The destructive effect seemed to be exactly of the kind which follows explosions of gunpowder and kindred substances. This could only occur through a gas being suddenly formed; but whether this would be the production of the vaporisation of a liquid or the formation of some new conditions of the atmosphere by the electricity itself cannot at present be determined. The first object struck by the lightning was the finial, and this was split into numbers of pieces in the direction of the grain of the wood, and the same effect was seen on all the upright posts down which the lightning ran; but, midway across the middle of the hut was a transverse beam, through which the flash passed. At this spot about a foot of the wood was torn off, but in a transverse or horizontal direction in the course of the grain. If a chisel had been driven into the cross beam it would have broken the wood exactly in the same manner; or, indeed, any other force acting on the middle of the splintered wood as an explosive. The coat, and more especially the shirt, showed the explosive force which had produced the rents still better. Although the rents ran down the arm, they had no appearance as if done by an instrument, but rather by a violent pull exerted from side to side, for not only was there one large rent, but similar partial ones running parallel to it. These could only have been done by forcibly stretching from within; in fact, the only way suggested would be an explosion of gas taking place in the shirt sleeve, and so forcibly thrusting it out, causing the fibres of the fabric to give way. The split boot, which was nearly off the foot of the child, could not be imitated except by placing a charge of dynamite within it."

Not professing to have much knowledge of what has been written on the modes and causes of the great destruction caused by lightning, I am writing to obtain more information on the subject. SAMUEL WILKS.

January 20.

The Probable Volcanic Origin of Nebulous Matter.

IN papers published some fifteen years ago (see, among others, Nos. 2 and 4 of *Contributions from the Lick Observatory*) I considered certain phenomena produced by streams of finely divided matter ejected from the sun, each stream necessarily taking on the form of a helix, and stated that the nebulosities surrounding certain stars were probably caused by the presence of streams similar to those which produce the solar corona.

In an effort to explain the fact that in certain spiral nebulas two diametrically opposite streams are, as a rule, most conspicuous, Prof. Chamberlin advanced the theory (see *Astrophysical Journal* for 1901, p. 17) that the disruption of one body through tidal action and centrifugal

force caused by the near passage of another body moving with great velocity would account for the observed phenomena. I am of the opinion that no forces except those originally resident in the central body itself are essential for the creation of such structures.

As a supplement to my note in NATURE for January 14, 1904, I now wish to offer a very simple theoretical explanation of the manner in which the ejective force becomes so very powerful.

As a result of the decrease in temperature from the centre to the surface of an incandescent mass exposed to the cold of space, the surface-crust finally formed will be punctured at various points by the imprisoned gases, thus also allowing the more refractory matter from the interior to overflow the region immediately surrounding each vent; the increased weight of the locally thickened crust causes the lower opening (of the channel formed) to be depressed below the general level; as the height of the surface-cone increases the simultaneously formed inverted cone is forced deeper and deeper into the regions of greater temperature and pressure, where matter exists in the form of compressed gases. The more easily volatilised materials of the depressed mass will be dissipated, leaving only the more refractory elements to form the inverted cone.

So long as there is a free flow of gaseous matter, the higher the volcanic cone the greater will be the ejective force, and, owing to internal reactions, diametrically opposite vents will be most powerful. We therefore reach, as it seems to me, the theoretical conclusion that *in the act of cooling, an originally incandescent body has the power to create conditions which will enable it to remove a part of its mass, in a finely divided state, to distances which may be far beyond the sphere of its own sensible attraction.*

On an Alleged New Monkey from the Cameroons.

IN NATURE for October 26, 1905, Dr. H. O. Forbes described, as representing a new species, a monkey (Guenon) from the Cameroons, which he named *Cercopithecus crossi* in compliment to Mr. Cross, of Liverpool, to whom it belonged. The description tallied so closely with that of *C. preussi*, based by Matschie in 1898 upon specimens also from the Cameroons, that I strongly suspected the two species would prove to be identical. That this is the case I have now no hesitation in affirming after examining the type of *C. crossi*, which Mr. Cross has sent to the Zoological Gardens in London.

Sounding Stones.

IT may be of interest to add to the list of musical stones provided by your correspondents another limestone, viz. the very hard, crystallised, coral rock of the coasts of British East Africa. Among the bizarre forms assumed by these rocks under the erosion of the sea, isolated pillars with projecting arm at the top, like a gallows or an inverted capital "L," are common in places. This horizontal arm in many cases gives a clear musical note when struck with a stone or hammer, being thus a ready suspended natural gong.

CYRIL CROSSLAND.

Broughton in Furness, January 18.

Chinese Names of Colours.

IN NATURE of January 11 (p. 246) Mr. A. H. Crook refers to some colour terms used by Chinese. *Ts'eng* (Cantonese) or *ch'ing* (Pekingese) is a vague Chinese term applied to black, grey, "neutral tint," ocean green, sky colour, blue, &c., but nearly always with a gloss or sheen upon it. The fresh turnip-like pears of China are called in Canton *süt*$_{\circ}$ *li*, or "snow-pears" (the small circle following the *t* indicating the "tone" of the word). Williams's Dictionary of 1878 gives *hsüeh-ch'ing* (Pekingese) or *süt*$_{\circ}$*-ts'eng* (Cantonese) as "a purple colour," and the allusion is evidently to that bluish glassy tinge that frozen snow takes, as seen in glaciers, icebergs, and so on; in short, all "vitreous" or glassy hues, from beer-bottles to mother-of-pearl, are *ts'eng*.

E. H. PARKER.

THE WORK OF THE NATIONAL ANTARCTIC EXPEDITION.[1]

CAPTAIN SCOTT is warmly to be congratulated on the two interesting volumes in which he describes the work of the National Antarctic Expedition and gives his conclusions as to its results. The book, naturally dedicated to Sir Clements Markham, is a most valuable contribution to the knowledge of what will probably always be one of the most interesting parts of the Antarctic continent. It is written in a charmingly easy and fluent style; the narrative is modest and frank; and the story is always pleasant reading, from its evidence of the uniform good temper which prevailed throughout the expedition, of Captain Scott's capacity for handling his men, of his sympathetic appreciation of their high endeavour, and of his keen interest in all branches of the work. The book is illustrated by a series of fine photographs, many of which were taken by Lieut. Skelton, and its value is greatly increased by the beautiful sketches of Dr. Wilson.

The story of the expedition is full of incident and adventure in most of which Captain Scott had a large share, as he exposed himself to its greatest risks. The two main achievements of the expedition are Captain Scott's fine sledge journeys with Dr. Wilson and Lieut. Shackleton to the farthest south, and with Evans and Lashly to the farthest west that was reached in Victoria Land. Both these undertakings were daring and arduous in the extreme. The sledge journey to the south reached the latitude of 82° 16′ 33″ from 77° 51′, and this spirited performance would probably have been even more successful but for the death of the dogs. The journey westward on to the plateau of Victoria Land Captain Scott describes as even more severe than that to the south, and regarding it he says:—"I cannot but believe we came near the limit of possible performance."

The scientific results of the expedition cannot yet be fully stated, as the collections and observations have not been worked out; and we shall have to wait in most cases for the reports of the experts to whom the material has been entrusted. Captain Scott's book contains accounts of the chief work in geography, in vertebrate zoology, and in geology. The Antarctic mammals and birds are described in an interesting chapter by Dr. Wilson, in which the most important contribution is the account of the life-history of the emperor penguin, which was studied on its breeding-grounds by himself and Lieut. Skelton. The volumes contain no technical information about the invertebrates, &c., and it is disappointing to learn that we cannot expect any additions to the deep-sea fauna of the Southern Ocean. The wealth of new material collected by the *Challenger* in its one deep haul in the Antarctic, led to hopes that valuable results would be achieved by the powerful deep-sea equipment of the *Discovery*; but apparently it was very little used, owing to the short time spent at sea, and possibly on account of the limited coal supply. One dredging is referred to at the depth of 610 fathoms, another at 100 fathoms, and a third, also in shallow water, off the great ice-barrier. The invertebrate fauna, of which Mr. Hodgson has already described elsewhere some of the more interesting discoveries, seems to have been chiefly collected under the ice in McMurdo Sound by means of his very ingenious devices.

The principal geological results are stated in a

[1] "The Voyage of the *Discovery*." By Captain R. F. Scott, C.V.O. Vol. i. Pp. xx+556. Vol. ii. Pp. xii+508; with two maps and 272 illustrations. (London: Smith, Elder and Co., 1905.) Price 42*s*. net.

valuable appendix by Mr. Ferrar, which is to be followed, in the volumes on the scientific work of the expedition, by a more detailed account of the rocks, and we may hope also by more precise information about the ice. Captain Scott describes the admirable pains devoted to the observations in physics and meteorology, the results of which are being worked out.

The geographical work—"surveyed under the direction of the R.G.S.," the chart informs us—is stated and discussed at length. The chief geographical results were achieved by the sledging parties. The results thoroughly justify those who advocated the selection of McMurdo Sound, or Bay as it was then called, as the winter quarters, owing to its high latitude, its exceptionally interesting geographical position, and its easy accessibility "great icy barrier," owing to the mystery suggested by its name, and perhaps, in part, to what, according to Captain Scott, was Ross's exaggeration of its height and uniformity. Ross's conclusion that this ice-sheet is afloat along its seaward face has been fully confirmed; and the important discovery has been added, by observations on a food depôt, that the ice is moving in one place at a rate estimated at 608 yards in $13\frac{1}{2}$ months. Captain Scott regards this ice-sheet, a smaller sheet in Lady Newnes Bay, and a mass ashore at Cape Crozier, as relics of a vast sheet of glacier ice, which once filled the whole of the Ross Sea, and floated when the reduction in its thickness rendered it buoyant.

The geographical problem of most importance is the form and area of the Antarctic continent. It is gratifying to those who believe in the value of geo-

FIG. 1.—Highest Ice-wall (280 feet) on the Ice-Barrier, showing the regular stratification. From "The Voyage of the *Discovery*."

in the summer. There is one quaint mistake in the book in reference to the main hut erected there, which is described (p. 215) as of a design used by "outlying settlers in that country" (Australia); whereas the design was based on Peary's Greenland hut, and the modifications, suggested by Australian experience, were devices used there to render the walls of the frozen meat warehouses impermeable to heat and cold.

The headquarters were established near Mount Erebus, which is still in quiet activity, and (disregarding the feelings of those who like scientific precision in geographical terms) the volcano is described throughout the book as giving forth smoke, fire, and flame.

The widest popular interest is perhaps felt in the graphical homologies, to find how fully the suggestions based on them have been justified by the work of the Antarctic expeditions. The important discovery of Coats Land by the Scotch expedition has revealed the southern shore of the Weddell Sea even further north than the position assigned to it in Sir John Murray's sketch-map. The German expedition has re-established faith in the continuity of the land, in an area where the soundings of the *Challenger* had thrown doubt on it, and where it was possible that there might be a deep southern indentation opposite the basin of the Indian Ocean.

The only serious alteration suggested in the outline of Murray's Antarctica is that the Pacific coast between Graham's Land and Victoria Land may possibly be further south than was expected. The

projection eastward of Ross Island and the peaks called by Ross the Parry Mountains, which were all regarded as part of the mainland, suggested that behind Ross's ice-sheet the mountains of Victoria Land trend to the east. Captain Scott tells us that the Parry Mountains do not exist; but a group of islands, White Island, Black Island, and Minna Bluff, occur in almost the same relation to Mounts Erebus and Terror as Ross marked his Parry Mountains. Behind this archipelago there is a great bight, the land first trending somewhat westward, and bending to the east after about 81° S. Thence, so far as Captain Scott could see, the land has an average trend to S.S.E. from Mount Wharton to the most distant southern peak observed beyond Mount Longstaff. Captain Scott concludes that the mountains continue in the same direction to Graham's Land. There is nothing *a priori* improbable in the connection of Victoria Land and Graham's Land along this line; for coasts of the Pacific type are characteristically straight for long distances, and have broad open curves rather than sudden bends.

This does not affect the essential part of my suggestion made in Nature, April 25, 1901, "that we may expect the greatest elevations on the Antarctic Lands will lie along the Graham's Land-Victoria Land line, and will be near the sea. To the south of the main mountain range there may be an undulating ice-covered region descending slowly across the Pole to the shore of the Weddell Sea. The main ice drainage would then be not from the Pole radially in all directions; the ice-shed would run along the Pacific Shore with a short steep northern face and a long gradual slope southward to the Pole and across it northward to the Atlantic." This view is fully supported by Captain Scott's opinion that, according to his view of the course of the main mountain chain, "the geographical pole would be situated 200 miles more from it, and on the high ice-plateau which must continue behind" (vol. ii. p. 427).

The lands, problematical and proved, to the south of the Pacific probably belong to one of those island festoons, which are still so characteristic, and apparently once occurred along all the Pacific coasts. The only objection to placing the main coastline of the South Pacific south-west of Ross's ice-sheet, instead of along a line north-eastward through King Edward Land, is the ice-barrier, on Captain Scott's theory of its formation. If it be land ice, and be flowing rapidly northward, a mile in three years, it must be fed from snow-fields among mountains to the south, and is probably confined between high lands to east and west.

Fig. 2.—A camp on the "Ross's Ice-Sheet," showing the snowy texture of the surface. From "The Voyage of the *Discovery*."

It is here that we feel most the need of more precise information regarding the ice of Ross's ice-sheet, as Ferrar proposes it should be re-named. That this ice is land ice flowing out to sea has been the generally accepted explanation of the facts described by Ross. The difficulty presented by Ross's ice-sheet, if it be advancing northward along its whole face at anything like the rate of the ice movement round Minna Bluff, is that its surface appears to be practically level, so far as it was followed by Royds to the south-east and by Scott to the south. Hence its rapid movement cannot be due to flow down a slope as in the case of ordinary glacier ice. The best

photograph of the ice (vol. i., p. 192) shows that it is very regularly stratified, and there is no visible interglacial material; the ice appears very different from that typical of glaciers. A photograph of a block of the barrier ice, of which the structure had been brought out by throwing over it a bucket or two of hot water, would have been very useful. The characters of glacier ice are so distinctive that any precise information as to the structure of the barrier ice would have left no doubt as to its nature. The photograph (Fig. 1) which gives most information about the ice suggests that, at least the part above sea-level (see also Fig. 2) has been formed by the accumulation of layers of snow upon the surface, more quickly than the ice was dissolved by the sea beneath. If this view of the origin of the ice sheet be correct, both its horizontal position and the gentle undulations of its surface are intelligible; and it forms no obstacle to belief in the connection of Graham's Land and Victoria Land along the shortest and most direct line. In this case Ross's ice-sheet will agree in character with the floebergs of Sir George Nares's Palæocrystic Sea, except that they were supposed to have grown by the additions of layers of ice from the sea below, instead of by the fall of snow from above. In this connection, some information as to the rate of solution and growth of the ice in sea-water at various temperatures would have been useful. Captain Scott tells us that such observations were suggested in the "Antarctic Manual." I have been unable to find there the passage referred to. The suggestion is, however, dismissed (vol. i., p. 305) as ridiculous. More than once during the course of the expedition the observations desired were accidentally noticed, but the conditions are not stated with sufficient precision to be of service.

The structure of Victoria Land, both geographically and geologically, is much as was expected from the considerations which led to the conclusion, first suggested by Ritter, that the eastern coast of Victoria Land represents the continuation of the volcanic line of New Zealand, and that a plateau occurs behind it. The discovery of the plateau structure seems to have occasioned surprise, though the hope was expressed in NATURE, April 25, 1901, p. 612, that one party would "cross the volcanic mountain chain to the plateau that probably lies beyond it." The geological structure, as described in Mr. Ferrar's interesting chapter, consists of low-lying archæan coast hills, beyond which occur sheets of horizontal sediments and broad sheets of plateau basalts. Huge volcanic cones occur off the main coast line, like the worn down volcanic hills of Dunedin and Bank's Peninsula in New Zealand, and apparently there are great volcanic cones on the plateau near its edge. It would be difficult to find land with a structure more typical of the Pacific coast type.

In contrast to the extensive discoveries achieved by the sledging parties from the winter quarters are the limited results obtained at sea, which make the title of the book, "The Voyage of the *Discovery*," somewhat of a misnomer. In the book 176 pages are devoted to describing the whole voyage of the *Discovery* from London to London, and 698 pages to describing the sledging and other work on shore. It was hoped that the *Discovery* would have thrown some light on the two chief problems offered by the outline of Antarctica, in the area reserved for the British sphere of operations. After the discovery of Coats Land by the Scottish expedition, the longest unknown stretch of the Antarctic coast is that south of the Pacific. It was believed from the work of Ross and Cook that land exists connecting Graham's Land to that on the eastern edge of the barrier. The *Discovery* has confirmed the existence of land close by the point where Ross described his "strong appearance of land"; but the necessity for the whole expedition returning to winter on McMurdo Sound prevented the discovery of its nature. Captain Scott seems disposed to regard this land as probably volcanic, and Mr. Ferrar as probably continental.

It was also hoped that the expedition would determine the character of the land to the west of Cape Adare; for a section along that coast, which cuts across the grain of the continent, would no doubt give more information as to its structure, than could be obtained along the coast of Victoria Land or by a traverse of the ice-clad interior. But here again the expedition had to return from the threshold of the unknown regions. This was Captain Scott's misfortune, and was in no way his fault. It was the result of the plan of the expedition being to keep the *Discovery* at the winter quarters. The limited work done by the *Discovery* at sea, and its inability to accomplish the much desired deep-sea trawling, is possibly due to the heavy demands on the available coal supply made by her engines; for the 500 horse-power which they gave required a large consumption of fuel, and this rendered impossible any prolonged period of full steaming away from a coaling station. Whether the *Discovery* was a complete success as a ship appears doubtful. Captain Scott praises many features in its design, and of its magnificent strength there can be no question. But in spite (vol. ii. p. 327) of what Captain Scott calls the "depth of sentiment" he naturally feels for the ship, "which for long proved such a comfortable home," he says that when they tested her sailing qualities they "found to our chagrin that they were exceedingly poor"; she had a fine capacity for rolling, sometimes going over 90°, and he describes (vol. ii. p. 375) her "lurching from side to side in the most uncomfortable fashion while our consort [the *Terra Nova*] followed in our wake with scarcely a movement." Her leakiness is described as a continual source of trouble, and the only expression of irritation in the book is at "another very stupid arrangement" in the ship (vol. i. p. 339). But for the somewhat meagre results achieved by the *Discovery* Captain Scott is not responsible; if the ship could have been kept at work at sea, while Captain Scott was doing his sledge journeys on land, a wider and richer harvest of results would doubtless have been obtained.

J. W. GREGORY.

RECENT ETHNOLOGICAL PUBLICATIONS FROM THE FIELD COLUMBIAN MUSEUM.[1]

OF peculiar interest is Dr. Dorsey's account of the ceremonial organisation of the Cheyenne, which dates back, according to tradition, to two or three thousand years ago, being founded by Motzeyeuff, a prophet who came as a messenger from the Great Medicine with four great medicine arrows, which were sent to the Cheyenne as an emblem for their future, as they possessed magic, and the Great Medicine decreed they should produce effects beyond natural powers. These arrows are still preserved, but two of them are in the hands of the Pawnee. The prophet organised five societies—the Red Shield, Hoof-rattle, Coyote, Dog-men, and Inverted Bow-string. The first two of these are concerned with

[1] Voth, H. R.: "Oraibi Natal Customs and Ceremonies." Field Columbian Museum, Chicago 1905. *Anthropological Series*, vol. vi., No. 2. "Hopi Proper Names," *ibid.* vol. vi., No. 2. "The Traditions of the Hopi," *ibid.* vol. viii.

Dorsey, G. A.: "The Cheyenne: I. Ceremonial Organisation," *ibid.*, vol. ix., No. 1. "The Cheyenne: II. The Sun-Dance," *ibid.*, vol. ix. No.

the capture respectively of the bison (buffalo), elk, and deer. The Coyote society derives its name from the fact that its members imitate the coyote in their power of endurance, cunning, and activity; they outstrip their fellow-tribesmen in running long distances, playing games, &c. The Dog-men were raiders. It would therefore seem evident that, judging from the analogies in Australia and Torres Straits, these are

FIG 1.—Self-inflicted torture by a Cheyenne, for performance of the sun-dance. The thongs are attached to the centre-pole. From a painting by a native artist.

in reality ancient totemic clans which were re-organised by the prophet and still retain their magical functions. The Inverted or Bow-string Warrior society is but little known throughout the tribe; it was founded by the prophet subsequently to the others; there was no chief, each warrior being independent of the rest, though all dressed alike and were always prepared for war. The close observance of the regulations of this society by its members gives them a character distinct from that of the other societies, and they are regarded as pure. They rejoice in the beauty of nature as the work of the Great Medicine, who created the rivers, hills, mountains, heavenly bodies, and the clouds. They are the philosophers among the people. Since the advent of the white man a sixth warrior society, the Owl-man's Bow-string or Wolf Warriors, has been founded; it alone, of all the warrior societies, dances with guns, and they shoot blank cartridges. This paper is illustrated by a number of plates, most of which are facsimiles of coloured drawings by Cheyenne artists; they illustrate the ceremonial costumes and paraphernalia of the members of the societies, as well as sun-dance myths; the drawings are so much in advance of those usually drawn by backward peoples as to suggest that the artists learnt from Europeans. It would have been an advantage if Dr. Dorsey had said a little more about the conditions under which they were executed; the idea of illustrating a memoir by native talent is a good one.

The Cheyenne sun-dance is described in considerable detail in a separate memoir, and is copiously illustrated with 105 figures, nearly all of which are from photographs, and some fifty plates, many of which are in colours. In 1903 Dr. Dorsey published an elaborate monograph on the Arapaho sun-dance (*cf.* NATURE, June 28, 1904), and now we have from his pen a companion account of the same dance as performed by another tribe of Plains Indians. The name given by the Cheyenne to the sun-dance is the New-Life-Lodge; according to the interpretation of the priest, the name means not only the lodge of new life, or lodge of new birth, but it is the new life itself. The performance of the ceremony is supposed to re-create, to re-form, to re-animate the earth, vegetation, and animal life; thus it is the ceremony of the re-birth. As one of the priests put it, "Formerly this dance represented only the creation of the earth. The Cheyenne grew careless and combined other things with the ceremony. At the time of the Love-tipi (or Sacred Lodge), though everything is barren (referring to the bare space made within the tipi), the earth is beginning to grow. Now it has grown. Thus they make the earth, buffalo wallow, grease, wool, and sinew to make growth. By the time of the end of the lodge things have grown, people have become happy; the world has reached its full growth, and people rejoice. When they use the bone whistle they are happy like the eagle, which is typical of all birds and of happiness."

It would take too long to describe the ceremonies, which are evidently very ancient and sacred. Thanks to the labours of Dr. Dorsey and other American colleagues, the religious symbolism of the Plains Indians is beginning to be understood, and researches such as these will afford valuable data to the students of comparative religion. The rite of sacrifice by means of self-inflicted torture was common to many of the Plains tribes, but, so far as is known, it was

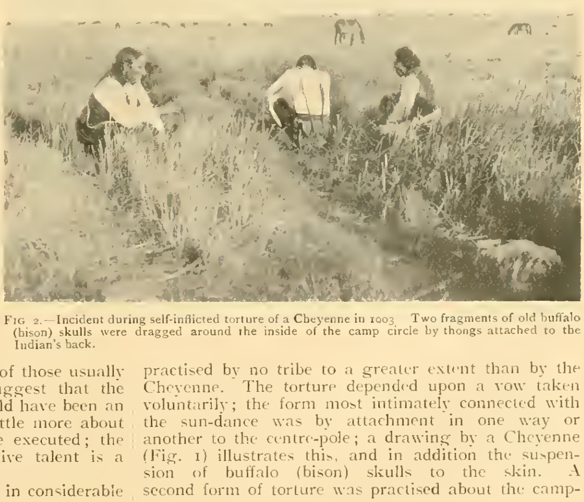

FIG 2.—Incident during self-inflicted torture of a Cheyenne in 1903 Two fragments of old buffalo (bison) skulls were dragged around the inside of the camp circle by thongs attached to the Indian's back.

practised by no tribe to a greater extent than by the Cheyenne. The torture depended upon a vow taken voluntarily; the form most intimately connected with the sun-dance was by attachment in one way or another to the centre-pole; a drawing by a Cheyenne (Fig. 1) illustrates this, and in addition the suspension of buffalo (bison) skulls to the skin. A second form of torture was practised about the camp-

circle rather than within the sun-dance lodge. Of this form the commonest method was for the dancer to drag one or more dried buffalo skulls attached to skewers inserted in his back, just as the skewers were inserted in the breast in the previous form of torture (Fig. 2).

Mr. H. R. Voth continues his valuable investigations on the Hopi Indians with a particularly interesting account of the customs and ceremonies connected with birth in Oraibi, the largest of the seven Hopi villages, and a suggestive paper on Hopi proper names. When a child is twenty days old it receives its first names from the grandmother, or other close relative on its mother's side, and from other women, all of whom must belong to the clan of the mother and child. The "child-name" is retained until the child is initiated into some order or society, when a new name is given, and at every subsequent initiation a fresh name is given. All Hopi proper names have some reference to the clan totem of the name giver, never, unless coincidentally, to the clan totem of the bearer of the name. The same investigator publishes 110 traditions of the Hopi, which were collected in the vernacular and without an interpreter.

A. C. H.

NOTES.

SIR WILLIAM THISELTON-DYER, K.C.M.G., F.R.S., has been elected a member of the American Philosophical Society.

BARON DE GUERNE has been elected president for 1906 of the Paris Geographical Society, M. E. H. Martel chief vice-president, and Baron Hulot general secretary.

THE editors of the *Geological Magazine* have issued invitations to a reception to be held on the evening of February 8, to commemorate the publication of the five hundredth number of that periodical.

PROF. KARL VON FRITSCH, president of the Leopold-Caroline Academy, and professor of geology and palæontology in the University of Halle, died on January 9 in his sixty-seventh year. Of his written works, the most widely known is his "Allgemeine Geologie."

FROM Basel we learn that Swiss engineers have sketched out a plan for connecting Switzerland with the North Sea and the Mediterranean by means of an immense canal system at an estimated cost of 324,000,000 francs. On the one side Rotterdam is to be reached from Lake Constance by means of the Rhine, and on the other side Lake Como is to be brought into connection with the Mediterranean by means of the River Po.

THE sum of nearly 2000*l.* has been given by Judge Holek (Denmark) for the purpose of effecting Porsild's plan of a biological station in Greenland, and the Danish Government has agreed to be responsible for a large part of the annual upkeep of the station, which is estimated to run to 11,000 kroner (111*l.*). The most eminent travellers in polar regions in general, and in Greenland in particular, have testified to the value of such a station.

ON Thursday next, February 1, Mr. Benjamin Kidd will begin a course of two lectures at the Royal Institution on "The Significance of the Future in the Theory of Evolution," and on Saturday, February 3, Mr. J. W. Gordon will deliver the first of two lectures on "Advances in Microscopy." The Friday evening discourse on February 2 will be delivered by Prof. S. P. Thompson on "The Electric Production of Nitrates from the Atmosphere," and on February 9 by Mr. H. F. Newall on "Eclipse Problems and Observations."

A NOTE special to Monday's *Pall Mall Gazette* announces that "a new system of wireless electrical communication that seems admirably suited for connection over distances of a few miles, and that possesses the advantage of cheapness, reliability, and secrecy in a degree that probably exceeds all the other systems, has just emerged from some very successful trials in Germany." The experiments described were made near Berlin by Mr. E. Ruhmer, but the "special" news referring to them adds nothing to the account of his system given in NATURE two years ago (February 18, 1904, vol. lxix., p. 373) in an article on "Photo-telephony."

MR. ELNAR MIKKELSEN, the young Danish explorer who, in conjunction with Mr. Leffingwell, an American, is organising an expedition to the Beaufort Sea, has just left this country for the United States. It is proposed that Mr. Leffingwell and other members of the expedition shall travel down the Mackenzie River in the early summer of this year, while Mr. Mikkelsen, should he be able to obtain a suitable vessel, will leave San Francisco in April, and after spending some time on the Siberian coast purchasing necessary equipment, meet the rest of the party at the mouth of the Mackenzie some time in the latter part of August. Thence the expedition will make its way to Cape Kellet, in Banks Land, and begin the exploration of its special region. The work to be undertaken depends to some considerable extent on the arrangements which it may be possible to make with regard to the fitting out of a ship.

AT a meeting at the Royal United Service Institution on January 18, Major Goodwin, D.S.O., delivered a lecture on "Military Hygiene on Active Service." After briefly describing the origin and causation of those diseases which affect armies in the field, and discussing and comparing the statistics of the Boer and Russo-Japanese wars, the lecturer suggested that there are two principal measures, which, if organised and perfected, will entirely remedy, in his opinion, the great evil which has existed in the past. The first measure is sanitary organisation—a corps should be formed of officers and men specially trained in all the methods of sanitation—the second is the necessity for the further education of regimental officers and men in sanitary principles.

THE annual general meeting of the Entomological Society of London was held on January 17. Mr. F. Merrifield, the president, read an address on the general operation of temperature on the growing organism of lepidopterous insects, based on a series of experiments, especially with reference to the remarkable limitations imposed by climatic and artificial conditions. The report of the society showed that for the first time in its history the number of ordinary fellows had reached five hundred. The officers and council were elected for the session 1906–7 as follows:—President, Mr. F. Merrifield; hon. treasurer, Mr. A. H. Jones; hon. secretaries, Mr. H. Rowland-Brown and Commander J. J. Walker, R.N.; librarian, Mr. G. C. Champion; other members of the council, Mr. G. J. Arrow, Mr. A. J. Chitty, Mr. J. E. Collin, Dr. F. A. Dixey, Mr. H. Goss, Mr. W. J. Kaye, Mr. H. J. Lucas, Prof. E. B. Poulton, F.R.S., Mr. L. B. Prout, Mr. E. Saunders, F.R.S., Mr. R. S. Standen, and Mr. C. O. Waterhouse.

DR. H. J. P. SPRENGEL, F.R.S., the inventor of the mercury air-pump, whose death we announced last week, was for three years an assistant in the chemical laboratory

of Oxford University; afterwards he worked in the laboratories of Guy's and St. Bartholomew's Hospitals, London. He was elected a Fellow of the Royal Society in 1878. His air-pump, which he described to the Chemical Society in 1865, led to results which had an important influence on the development of both science and industry in the latter part of last century. It provided a convenient method of obtaining vacua of very high tenuity, and contributed greatly to the perfection of the incandescent electric lamp. Dr. Sprengel devoted much time to the study of detonation and explosives, and in 1871 took out patents for a class of explosive substances which were non-explosive during their manufacture, storage, and transport. He was the first to direct attention to the value of picric acid as an explosive when fired by a detonator. In addition to papers on his vacuum pump and kindred subjects, Dr. Sprengel published the following contributions to science among others:—Atomised water as a substitute for steam in a chemical process, 1873; improvements in explosive compounds, 1871; on a new class of explosives, 1873; the Hell-Gate explosion near New York and so-called "Rackarock," 1886; the discovery of picric acid as a powerful explosive and of cumulative detonation with its bearing on wet gun-cotton, 1902.

THE fifty-fifth meeting of the American Association for the Advancement of Science was held at New Orleans, and began on December 29 last. The membership of the association has now reached 4500. It has been decided to hold two meetings during 1906, one in the summer at Ithaca, N.Y., the other in the winter at New York City. At the recent meeting, the address of the retiring president, Prof. W. G. Farlow, dealt with the popular conception of a scientific man at the present day. The presidents of the different sections delivered their addresses on various days throughout the meeting. Prof. Ziwet, at the first meeting of the section of mathematics and physics, took for his subject the relation of mechanics to physics. Prof. Kinnicutt, in the section of chemistry, considered the sanitary value of a water analysis. Prof. Merriam, in the section of zoology, discussed the question, Is mutation a factor in the evolution of the higher vertebrates? The subject of the partition of energy was taken up by the president of the physics section, Prof. Magie; and the generic concept in the classification of the flowering plants was dealt with by Prof. Robinson in the section of botany. Prof. Knapp, in the section of social and economic science, considered the subject of transportation and combination. In the section of mechanical science and engineering, Prof. Jacobus addressed the meeting on commercial investigations and tests in connection with college work. The experience at New Orleans makes it doubtful whether the experiment of scattering the addresses of the presidents of sections through a week is a wise departure.

WE have received copies of the reports of the Bristol Museum and Reference Library for 1904, and of the Bristol Museum and Art Gallery for 1905. The change in the title of the institution is due to the opening of the Art Gallery, which took place in February of last year, when the inaugural address was delivered by the late Prof. Herkomer. About the same time Mr. F. G. Pearcey entered the museum as assistant curator, and since his appointment a thorough re-arrangement of the zoological exhibits has been undertaken, while large additions have been made by gifts and purchase.

BOTANICAL surveys undertaken with the object of studying the distribution of plants over a limited area have been prepared by several workers in Scotland and England. Mr. G. H. Pethyridge and Mr. R. L. Praeger publish in the *Proceedings of the Royal Irish Academy* (vol. xxv.) a survey of the vegetation of the district lying south of Dublin. The authors distinguish four zones, littoral, agrarian, hill pasture, and moorland. It was observed that the three associations of *Ulex Europaeus*, *Ulex Gallii*, and Calluna maintain a definite succession in altitude, *Ulex Europaeus* occurring at the upper limit of the agrarian zone, and Calluna forming the most important feature of the moorland. The association in which Pteris is the dominant member occupies positions in each of the three former associations, holding its own where it is favoured by well-drained soil and a sheltered situation. The paper is accompanied by six illustrations, of which the one reproduced shows the characteristic rounded hummocks of *Ulex Gallii* in the foreground; in the background the farmland is seen below with *Ulex Europaeus* just visible in the middle distance and Calluna clothing the summit of the hill.

Photo. *R. Welch.*

FIG. 1.—Piperstown Hill, showing, in ascending order, farm land, *Ulex Gallii* association, and Calluna association.

THE educational advantages of the Central Museum at Brooklyn, New York, form the subject of the first article in the January issue of *Museum News*, in which attention is specially directed to the exhibits of typical groups of mammals, birds, and reptiles. It would seem, however, that the museum authorities themselves stand in need of education, otherwise they would scarcely have stated "that the present revolution in Russia bids fair to complete the extermination of the European bison by killing off the Lithuanian herd." They appear to be quite unaware of the existence of this animal in a truly wild state in the Caucasus.

In addition to several papers relating to the human subject, the January issue (vol. xl., part ii.) of the *Journal of Anatomy and Physiology* contains contributions on the anatomy and development of the lower mammals. Among these is one by Dr. T. H. Bryce on the development of the thymus gland in the lung-fish, *Lepidosiren paradoxa*, in the course of which the author arrives at the important conclusion that, at least up to an advanced larval condition, this organ has absolutely nothing to do with the development of leucocytes. Apparently the leucocytes take origin in a tract along the hind kidney, and, at any rate, there is evidence of their existence before the thymus cells have lost their epithelial characters. In another paper Prof. Symington discusses the bearing of the structure of fœtal whale-flippers on the development of additional digits and joints in the hand and foot of vertebrates generally. In cetaceans the suppression of nails or claws has led to the development of a cartilaginous rod at the end of each digit which is apparently a reversion to the primitive mammalian condition. "Such a condition would obviously facilitate the development of additional cartilaginous elements to adapt the limb to its newly acquired function as a balancing and steering organ." Hence the occurrence of "hyperphalangism" is easily accounted for, while indications of incipient "hyperdactylism" are afforded by rudiments in some cases of the development of a sixth digit.

In the annual report of the Botanical Department, Trinidad, for the year 1904–5, the superintendent, Mr. J. H. Hart, directs attention to the advantages of budded over seedling oranges in maintaining the qualities of any selected strain. Trinidad oranges have been successfully transported to England from time to time, and last year a consignment of mangos was sent over that carried well, and was said to compare favourably with the best Indian fruit. Among shade trees for cacao, *Gliricidia maculata*, the "Madura" of Central America, has been in considerable demand, and Honduras mahogany has also been planted. The cotton experiment plots suffered severely from the "boll rot."

Mr. D. McAlpine records in *Annales Mycologici* (vol. iii., No. 4, 1905) the discovery of a peculiar set of rusts on species of Acacia in Australia that he places in a new genus, Uromycladium. The characteristic of the genus is a branched carpophore producing at the ends of each branchlet one to three separate teleutospores, or in place of one of the teleutospores a colourless vesicle or cyst. Mr. McAlpine regards the genus as a link between Uromyces, which has a single teleutospore, and Ravenelia, a peculiar genus in which the stalk is compound and a number of spores are joined together at the top, with vesicles below. Of the seven species enumerated, uredospores and spermogonia are known for some, but no æcidia have as yet been found.

The *Times* of January 12 contains a comprehensive summary of the rainfall of 1905, by Dr. H. R. Mill. The work is valuable from a double point of view—from the vast amount of material relating to the rainfall of the British Islands that Dr. Mill has at his disposal, and from the almost incredible shortness of time in which he has been able to compile his statement, in advance of the usual annual rainfall volume, which takes at least six months to produce. The author points out that during an average year no spot with a fall of less than 20 inches appears on the rainfall map of Great Britain; last year there were about 7500 square miles, while the area with rainfall exceeding 40 inches measured some 29,000 square miles, or less than a quarter of the country. In an average year more than a third of the area of the country has a greater fall than 40 inches. A table based on a thirty years' average which accompanies the paper shows that none of the fifty-one stations quoted for England and Wales reached the normal amount, that only one did so in Ireland, and about half the stations in Scotland. From these figures Dr. Mill estimates that the general rainfall for England and Wales was only 83 per cent. of the average; for Ireland, 89 per cent.; for Scotland, 96 per cent. In other words, for every inhabitant of the British Isles there was last year 224,000 gallons less rain than in an average year. Further, that the year 1905 has justified the three years' cycle of one wet year followed by two dry years; the probability of 1906 proving a wet year has not been contradicted by the weather of the first half of January.

Mr. van der Grinten, whose projection of the whole globe in a circular map, published last year, attracted considerable attention, deals with another case—that of the "apple-slice" shape—in *Petermann's Mitteilungen* (p. 237, 1905).

Dr. Gerhard Schott contributes a paper on the relief of the bed of the Southern Ocean, and the distribution of bottom temperatures, to *Petermann's Mitteilungen* (No. 11, 1905). The soundings and temperature observations of recent expeditions are made use of, and the author has compiled an admirable bathymetrical chart showing the state of our knowledge of the region in 1905.

The *Zeitschrift der Gesellschaft fur Erdkunde* (No. 9, 1905) contains a paper on the geographical conditions determining the distribution of moorlands, by Dr. F. Solger. The chief factors taken into consideration are rainfall, surface topography, and elevation, and the relations of these three factors in different types of moorlands are discussed.

The publishers of *l'Elletricista* have issued a useful little book, by Dr. G. Agamennone, under the title of "La Registrazione dei Terremoti." The words "in Italia" should have been added to the title, as the book is confessedly devoted to Italian work, and hardly refers to that which has been done elsewhere, especially in Japan, where the ideas embodied in the Italian instruments were, with few exceptions, anticipated in the publications of the Seismological Society of Japan. The omission is justified by the plea of the author that any attempt at adequate recognition of the work done in other countries would have swollen the book to an undesirable size; as it is, we have a well got up and clearly written account of the seismoscopes and seismographs used in Italy, which are singularly efficient if somewhat more cumbrous than the English or Japanese patterns.

The *Rendiconto* of the Bologna Academy (vols. v.–vi.), covering the period 1900–2, has just been sent out. It contains a series of illustrated papers by Dr. Francesco Crevatin on the terminations of nervous systems; also papers by Prof. Augusto Righi on the magnetic field of a moving charge and on the acoustic properties of condensers, by the late Prof. Emilio Villari on the heating effects of electric discharges and on Röntgenised air, by Prof. Ferdinando Paolo Ruffini on the three cusped hypocycloid, and others.

We have received the annual report of the Circolo Matematico di Palermo, which shows an increase in its membership roll from 27 in March, 1884, and 195 in

March, 1904, to 255 in March, 1905. Of these 36 are resident, 138 non-resident, and 81 foreign members. The society owes its present position as a mathematical society of international rank largely to the personal exertions of Prof. Guccia, and further evidence of this activity is shown by the offer of a "Guccia medal" and prize of 3000 francs, to be awarded at the mathematical congress at Rome in 1908, for the best essay marking an advance in the theory of algebraic twisted curves.

MR. HENRY FROWDE has published an edition of Wordsworth's "Guide to the Lakes," with an introduction, appendices, and notes by Mr. Ernest de Sélincourt. Though Wordsworth is, throughout the book, rather the lover than the student of nature, yet the volume contains much that will appeal in a special manner to men of science—for example, the remarks on stone circles—and everything the volume contains will serve to increase the enthusiasm with which scientific students approach natural phenomena.

THE 1906 issue of their "Nature Calendar" has been published by Messrs. George Philip and Son, Ltd. It is a little difficult to understand the plan on which the notes for the months have been arranged, and on what principle the entries for successive days have been selected. Under the date January 25, for instance, are to be found the following statements:—"Jackdaws begin to come to churches"; "First appearance of Yellow Wagtail"; and "Honeysuckle leafing." A young, uninitiated nature student, who observed a jackdaw going to church, or came across a yellow wagtail, or found honeysuckle in leaf before January 25, might have his faith in naturalists' calendars seriously shaken.

A SECOND edition of Prof. Douglas H. Camphell's work on "The Structure and Development of Mosses and Ferns" has been published by Messrs. Macmillan and Co., Ltd. The first edition was published in 1895, and was reviewed at length in our issue for January 2, 1896 (vol. liii. p 194). Portions of the work have been re-cast entirely, this being especially the case with the eusporangiate ferns. The whole book has been carefully revised and new matter has been introduced, including two special chapters on the geological history of the Archegoniates and the significance of the alternation of generations. Some of the new material is published now for the first time, but much of it is based upon papers written by Prof. Campbell during the last ten years.

OUR ASTRONOMICAL COLUMN.

PERIODICAL COMETS DUE TO RETURN THIS YEAR.—Writing to the *Observatory* (No. 366), Mr. W. T. Lynn directs attention to the fact that two known periodical comets are due to return during the present year—Holmes's comet in the spring, Finlay's in the summer. The former has already been noted in these columns. Finlay's comet was discovered at the Cape on September 26, 1886, and performed its perihelion passage on November 22 of the same year; its period is about 6·6 years, and on its return in 1893 it was first seen by the discoverer himself, and passed perihelion on June 16. On its return in 1899 the comet was unfavourably situated for observation, and so escaped detection.

A note published in No. 1, vol. xiv., of *Popular Astronomy* mentions six other periodical comets as being due this year, viz. Barnard's (1884 II.), E. Swift's (1894 IV.), Denning's (1881 V.), Swift's (1889 VI.), and the two lost comets, Biela's and Brorsen's. Of these, the first and second will be unfavourably placed for observation; the third has not been seen since 1881, but will be more favourably placed this year; the fourth was very faint in 1889, and any small change in the period may have rendered it wholly invisible.

THE ANNULAR NEBULA IN CYGNUS (N.G.C. 6894).—An interesting photographic study of the very faint annular nebula N.G.C. 6894 has recently been made at the Meudon Observatory by M. G. Tikhoff. Using the 39-inch reflector, the observer obtained four photographs, of which he has measured the two best, taken on September 27 and October 27 with exposures 2h. 20m. and 3h. respectively.

These photographs showed the nebula to have the form of an elliptical ring with a condensation in the centre, the space between the nucleus and the outer ring being fairly bright. The extremities of the major axis of the ellipse are sharp, but several faint appendices are clustered around the ends of the minor axis. Measurements of the plate obtained on September 27 showed the length of the major axis to be $44''.8$, that of the minor axis $37''.3$, but if the appendices be included the length of the latter becomes $50''.8$. The nebula really consists of two rings, a broad outer one and a narrow inner ring, but the duplication is interrupted on the north-west by the star discovered by Lord Rosse in 1855. The outer ring has several condensations in it, of which the two brightest are nearly opposite to Lord Rosse's star.

M. Tikhoff recalls the fact that all observers of this nebula have commented on its similarity to the ring nebula in Lyra, and advances the opinion that it is probably in a later stage of development, for whereas the Ring Nebula has only one condensation, this Cygnian nebula has many.

RIGHT ASCENSIONS OF THE EROS COMPARISON STARS.—In Nos. 4059–4060 of the *Astronomische Nachrichten*, Dr. Fritz Cohn, of Königsberg, gives a catalogue containing the definitive positions of the Eros comparison stars contained in the two lists iussed by the international committee. The positions are given for 1900·0, and two supplementary tables give the proper motions necessary for reducing the places of the few stars known to be in motion to the equator of 1901·0.

OBSERVATIONS OF NOVA PERSEI (NO. 2) AND NOVA GEMINORUM.—The results of a series of magnitude observations of Novæ Persei and Geminorum are given in No. 4066 of the *Astronomische Nachrichten* by Dr. K. Graff, of the Hamburg Observatory. The Nova Persei observations extend from March 11, 1902, to August 24, 1905, and show one or two apparent oscillations of the brightness. On the latter date the magnitude of this star was recorded as 10·73.

The record for Nova Geminorum contains the results of six observations made between September 16, 1903, and November 10, 1904, and shows an apparent increase in the brightness between January 20, 1904, and the final observation; the latter was, however, somewhat uncertain, and gave a magnitude of $<12·0$.

On November 28, 1905, Prof. Max Wolf found that the magnitude of Nova Persei on the Pickering scale was 11·65, but compared photographically with the stars given by Father Hagen the magnitude came out as 10·6.

DOUBLE STAR ORBITS.—Prof. Doberck publishes four possible orbits for τ Ophiuchi and two for γ Centauri in No. 4063 of the *Astronomische Nachrichten*. Of these, he finds, on comparison, that the following agree most closely with observational results:—

τ Ophiuchi	γ Centauri
$\Omega = 76^\circ\ 12'$	$\Omega = 3^\circ\ 21'$
$\lambda = 17\ 45$	$\lambda = 285\ 2$
$\gamma = 66\ 4$	$\gamma = 81\ 47$
$e = 0·5338$	$e = 0·2958$
$P = 223·82y.$	$P = 211·93y.$
$T = 1814·79$	$T = 1851·63$
$a = 1''·307$	$a = 1''·924$

The value of the hypothetical parallax for τ Ophiuchi is $0''·035$, and for γ Centauri $0''·054$. In the elements of the latter, the epoch and the longitude of periastron are somewhat uncertain, and for this star the motion is retrograde.

ECONOMIC GEOLOGY IN THE UNITED STATES.

THE energy shown by all branches of the United States Geological Survey increases year by year, and it is impossible to overestimate the importance of the results achieved during the twenty-five years of its existence. The prompt return made for the pecuniary support accorded to the survey is best shown by the numerous publications, appearing each year, which are devoted to the development of the mineral resources and to the advancement of important engineering projects. The miner is thus taught the practical value of geological work, and mining development is placed upon a scientific basis. A large number of bulletins have recently been published which, though describing researches of an essentially scientific nature, deal with the economic resources of specified districts. Half a dozen of these bulletins, well illustrating the educational value of the survey's work to those engaged in the mining industry, have been selected for brief notice. Of these the most important is No. 260, "Contributions to Economic Geology, 1904," in which Mr. S. F. Emmons and Mr. C. W. Hayes, the geologists in charge of the sections dealing with ores and non-metallic minerals respectively, bring before the public with all possible speed the economic results arrived at by the survey. The bulletin covers 620 pages, and contains sixty-three contributions from thirty-seven members of the survey who have been engaged throughout the year in economic work. The production of gold and silver in the United States in 1904 is discussed by Mr. W. Lindgren, who has made a novel classification of the ores into (1) placer or detrital deposits, and (2) ores from rock *in situ*, further subdivided into quartzose ores, copper ores, and lead ores. The percentage of the total production derived from the four classes thus established is as follows:—

FIG. 1.—Weathered Surface of Galena Limestone near Rockdale, Iowa.

	Placers	Quartzose	Copper	Lead
Gold	15·2 ...	74·3 ...	5·0 ...	5·4
Silver	0·1 ...	22·2 ...	34·7 ...	42·9

A similar calculation of the copper production of the United States, made by Mr. W. H. Weed, shows that of the copper produced 27 per cent. occurs in native ores, 6 per cent. in oxide ores, and 67 per cent. in sulphide ores. Mr. L. C. Gratton reports that the tin deposits (dykes of pegmatite carrying cassiterite) of North and South Carolina are probably of considerable economic importance; and Mr. F. L. Hess gives a concise statement of what is known with regard to tin deposits throughout the rest of the world. In the Birmingham district, Alabama, an important result of the work of the survey has been the extension of the red hæmatite ore beyond its supposed southern limit.

The fuel resources of the United States received more attention last year than at any previous time during the existence of the survey. About 3000 square miles of coal-bearing territory have been mapped, and work in the oil and gas fields has been continued. The American cement industry formed the subject of an extensive investigation by Mr. E. C. Eckel, and much valuable information is given regarding the slate, granite, and clay industries. Descriptions are also given of a molybdenite deposit in eastern Maine, and of the vanadium and uranium ore deposits in south-eastern Utah.

Bulletin No. 255, on the fluorspar deposits of southern Illinois, by Mr. H. Foster Bain, embodies the results obtained in a detailed study of the fluorspar deposits in Pope and Hardin counties, the area covered being at present one of the most important producers of fluorspar in the United States. The deposits were discovered in 1830, but were not mined until 1870. The mineral occurs in veins along faulting fissures, and is associated with calcite, galena, and zinc-blende. In 1903 the district produced 11,413 tons of fluorspar, valued at 11,544*l*. The best grade of fluorspar, with less than 1 per cent. of silica, is used in the enamelling, chemical, and glass trades. The second grade is used in open-hearth steel making to give fluidity to the slag. About 20,000 tons are used annually in this work. The lowest grade is used in foundry work.

The zinc and lead deposits of north-western Illinois are dealt with in Bulletin No. 246 by Mr. H. Foster Bain. The region contains large reserves of zinc ore of good quality. The main ore-bearing rock is a thick massive dolomite, known as the galena limestone. Owing to the predominance of solution over disintegration, it presents on weathered surfaces a very characteristic carious surface (Fig. 1).

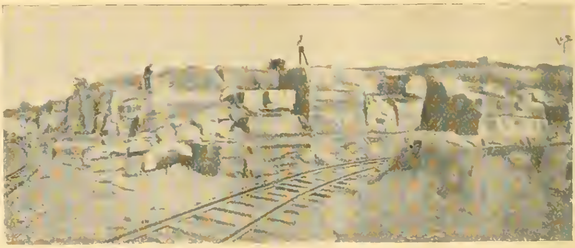

FIG. 2.—Vanport Limestone Quarries at Newcastle, Pennsylvania.

Bulletin No. 249, on limestones of south-western Pennsylvania, by Mr. F. G. Clapp, is of great economic interest in view of the recent extension of the portland cement industry. It points out promising localities for the erection of cement plants in the coal areas of Pennsylvania. As a rule, these Carboniferous limestones are not suited for building stone, but many of them, when burned, form lime of excellent quality for agricultural, building, and fluxing purposes. The Vanport limestone, the most per-

sistent, thickest, purest, and most massive limestone in the series, is extensively quarried for furnace flux at Newcastle (Fig. 2).

In Bulletin No. 238 Messrs. G. I. Adams, E. Haworth, and W. R. Crane give detailed information concerning the geology of the Iola Quadrangle, Kansas, a rapidly developing petroleum and natural gas field. At the end of 1903 there were 1596 producing wells in Kansas, and of these 549 were at Chanute (Fig. 3) and 339 at Humboldt in the area under consideration. Natural gas is abundant in the vicinity, and is largely used in zinc smelting. Indeed, more than half the zinc made in the United States is smelted by Kansas gas, and more than half of this is produced at works within the Iola quadrangle.

FIG. 3.—Golden Oil Company's Well No. 2, near Chanute, Kansas.

Bulletin No. 264, by Messrs. M. L. Fuller, E. F. Lines, and A. C. Veatch, gives a record of deep-well drilling for 1904, and is the first of a proposed series of annual publications. The report embodies the records of a large number of wells, for many of which sets of samples are preserved.

THE APPLICATION OF SCIENTIFIC METHODS TO THE STUDY OF HISTORY.[1]

THE remarkable change which during the last fifty years has passed over most subjects of study owing to the growing dominance of the scientific spirit has not left history unaffected. The leading historians of the present day are essentially men of science. They are diligent in their pursuit of truth and skilled in the special methods of research which their subject demands. They are strikingly impartial in their judgments, constantly on their guard against the prepossessions so liable in matters of past politics to bias opinion. They are ever on the alert to discover unifying principles, general laws, large uniformities, without which no body of historic facts, however accurately ascertained and however impassionately selected, can justify the claim of history to be regarded as a science, or can make history worthy of the serious attention of intelligent men.

All the writers enumerated at the foot of this column deal in some shape or form with this transference of history from the domain of literature to the domain of science. None states the fact of the transference more clearly than does Prof. Bury, who says (p. 16):—"I may remind you that history is not a branch of literature. The facts of history, like the facts of geology or astronomy, can supply material for literary art . . . but to clothe the story of a human society in a literary dress is no more the part of a historian as a historian, than it is the part of an astronomer as an astronomer to present in an artistic shape the story of the stars"; and again (pp. 7 and 42) he emphatically asserts that "History is a science, no less and no more." But though this statement is perhaps more explicit than any other in the works before us, yet the idea which it expresses is common to all.

It is not enough, however, to assert that a subject, long regarded as a branch of literature, is really a science. It is necessary to define its scope, to expound its method, and to show its relation to other sciences. This our authors do in varying degrees of fulness, and it would be a profitable, and I think not uninteresting, task to take them one by one and to analyse their views. But in an article like the present it is not possible to undertake this detailed examination, and I must content myself with giving a summary statement of the way in which scientific method has been applied to history, and of some of the results which have been attained.

It is a curious and remarkable fact that the earliest of the above-named exponents of the science of history, Droysen and Froude, were called upon to cast their first clear utterances upon the subject into the form of a severe castigation of a too zealous champion of their own view, H. T. Buckle. Buckle had become possessed of the great idea commonly associated with the name of Comte, viz. that "all phenomena without exception are governed by invariable laws with which no volitions natural or supernatural interfere," and in his "History of Civilisation" (1858–61) he had endeavoured with wonderful ingenuity and vast learning, not so much to elevate history to the rank of a science as to reduce it to the level of a *physical* science, with laws of the same rigidity and of the same universal applicability as the laws of motion or the laws of chemical affinity. This was going further than either the most advanced historians or the least exclusive philosophers would allow, and a keen controversy ensued, out of which at length emerged into general recognition the important fact that history differs from the natural sciences in at least two respects, first, that, with regard to its method, it is a science, not of observation or of experiment, but of criticism; secondly, that with respect to its generalisations, since they deal with a realm, not of matter, but of mind, in which motive and not force is supreme—a realm of consciousness and freedom—they can never have that fixity and universality which are connoted by the term "law."

On the other hand, historical phenomena are not permanent, but evanescent. Events happen once, and then fade beyond recall into the past. Observations made at the moment of their happening can never be repeated, and historians are dependent for all their knowledge of bygone events upon such records as may chance to have been made and to have been preserved. These records are the only present and concrete facts with which historians come into contact. These are the basal material of their science. But they are valuable and important, not at all for their own sake, but only for what they reveal. They reveal past facts, yet even these not directly, but past facts as seen through the refracting medium of the human mind. And when the historian has eliminated, so far as he can, the personal factors for his records and has extracted such pure and unadulterated fact as remains, even then he has not come to the end of his research. Far beyond and beneath all events there lie the thoughts, the acts of will, the emotions of which they were the realisations and manifestations—ultimate facts of the human spirit wholly beyond the observation even of those in whose midst the events transpired. It is these for which in the last resort he seeks. Thus, as has been remarked, history is a science, not of observation, still less of experiment: it is a science of criticism.

On the other hand, with regard to generalisation and law, the fundamental truth to be recognised is that history never repeats itself. The phenomena of history are not

(7) "A Plea for the Historical Teaching of History." By Prof. C. H Firth. (1904)
(8) "The Methodical Study of Man" By Dr. Percy Gardner. (1904.)

stationary like those of the experimental sciences which can be called up at will at any moment; they are in constant movement. Moreover, their movements are not cyclical, like the movements of the planets; they are progressive in an infinite series. Every event which occurs adds something to the environment of every subsequent event and is a factor in its causation; so that the mere fact that a thing has happened once presents an insuperable barrier to its ever happening again. We of the present day, for instance, are divided by an impenetrable wall of new ideas, new discoveries, new conditions from our predecessors of but the last generation. Not even the most deliberate and carefully planned attempts to revert to earlier orders of things—social, religious, political—can possibly result in anything but hopeless failure. History can never be *made* to repeat itself.

That being the case, it is obvious that whatever may be the general principles which historians may deduce from their study of historic phenomena, they will be very different from the rigid and invariable laws of natural science which enable the expert not only to explain the past, but also to predict the future. History, in fact, has closer analogies with the mental and moral sciences than with the natural sciences. It is to the human race almost exactly what memory is to the individual man. No individual man ever finds himself twice in precisely the same situation, nor can anyone discover unvarying sequences of cause and effect in the relations between himself and his fellows; yet, notwithstanding this, every man in his mature life is very largely guided and governed by his experiences as recorded by his memory and by the principles of conduct which his judgment has deduced from them. As with the individual so with the race; but subject to this important difference, that the race lacks that personality, that continuity of self-consciousness, which marks the individual. It has no natural memory, and in order that it may not lose the vast accumulated wealth of the experiences of the past a memory has to be created for it. That race-memory is history. Through history mankind attains to self-consciousness. As Droysen puts it:—"Die Geschichte ist das γνῶθι σαυτὸν der Menschheit, ihr Gewissen." By means of this self-knowledge humanity is able to become to a degree otherwise wholly impossible the master of its fate; it is able to control its destiny, and to move deliberately forward on the pathway of progress.

Now if history is to perform adequately its high function, and to serve the purpose of a universal memory to man, it is plain that it must no longer be left in the hands of the literary artist to be built up of anecdotes, be they told never so brilliantly, or in the hands of the party-politician to be constructed of half truths, be they never so honestly held to be the whole truth. History must be elaborated by the strictest methods of science, even though it is concerned with facts which are beyond the reach of observation and with principles which are not reducible to the satisfying simplicity of law. To state the matter in the briefest outline, which is all that is possible here, scientific method must be applied to history, first, in the discovery of facts; secondly, in the selective classification of facts; and thirdly, in the drawing of inferences from facts.

(1) *The Discovery of Facts.*

In history, the discovery of fact resolves itself mainly into the criticism of documents. So important are documents in historical research that MM. Langlois and Seignobos go so far as to say, in the opening paragraph of their book, "L'histoire se fait avec des documents," and "Pas de documents, pas d'histoire." There *are*, however, other sources of information, for example, oral tradition in the case of contemporary or recent events; archæological, architectural, and monumental remains in the case of more remote eras. Nevertheless, it is correct to say that documents are the primary source of historical knowledge. Concerning documents, the first thing which has to be determined by criticism is their origin—that is to say, their authorship, the date and place of their composition, and their genuineness. Many things have to be taken into account in the determination of these important matters, *e.g.* handwriting and writing materials, vocabulary, internal evidence of knowledge displayed and opinions expressed. When, so far as is possible, the origin of a document has been fixed and its genuineness proved, the problem of the accuracy of its statements has to be entered into. Such questions have to be asked as:—Had the writer opportunities of knowing what he wrote about? Had he sufficient ability to avail himself of his opportunities? Had he any prejudices to distort his judgment? Had he any reason to conceal or pervert the truth? Does his testimony agree with that of other witnesses? Is what he says inherently credible?

(2) *Selection and Classification of Facts.*

The fact that a fact is a fact does not make it important. The historian has to select the facts which are significant from vast masses of the insignificant. What shall be his principle of choice? Shall he select anecdotes which may amuse his readers, or incidents which support the views of some party or sect to which he belongs? The day when he could adopt either of these principles of selection is gone. But even now historians do not by any means agree as to the exact kind of facts that it is the function of history to record. Nor is it necessary that they should agree; no two people store their memory with precisely the same kind of recollections. Seeley and Freeman limited themselves to facts of past politics; Green and Macaulay recorded facts of past social conditions; Droysen and Döllinger, following Schopenhauer and Hegel respectively, looked below the surface of events, the one for the acts of will, the other for the movements of ideas of which events were the manifestation. Any one of these principles, or any similar principle, is sufficient to give a scientific unity to historical research.

(3) *The Drawing of Inferences from Facts.*

Although, as already seen, historical inferences can never have the characteristics of physical laws, and although the completest philosophy of history could never enable the historian to predict revolutions with that unerring certainty with which the astronomer predicts eclipses, yet historical inferences may be thoroughly scientific, and the philosophy of history of the greatest practical value. Given the permanent and unchanging facts of human nature, and known the peculiar circumstances of any particular event, that event can be explained; and though it is true that these circumstances can never by any possibility recur again, yet others will certainly occur sufficiently similar to make the explanations discovered in the one case valuable guides to conduct in the others. Social and political progress and the development of civilisation depend very largely on the adequate learning by the human race of the lessons of experience remembered by means of history.

If in our days kings are benevolent, churches are tolerant, armies are obedient, and policemen are civil; if colonies are well governed; if taxation is equitable; if Ministers of State are honest—all this is due no little to the recorded and thus remembered fates of tyrants, persecutors, rebels, and the rest. Similarly if the admitted imperfections of the present are to be removed, and if progress is to continue, history, rich with its lessons of the past, must remain the light and guide of the future. But it must be not the history of superstition and prejudice and romance, not the boon companion of astrology and alchemy, but the history of exact knowledge and calm judgment, the recognised members of the hierarchy of the sciences.

F. J. C. HEARNSHAW.

PUBLIC SCHOOLS SCIENCE MASTERS' CONFERENCE.

THE annual meeting and conference of the Public Schools Science Masters' Association was held on Saturday, January 20, at Westminster School. Owing to ill-health, which had forced him to go abroad, the president, Sir Oliver Lodge, was unable to be present, and the Rev. E. C. Sherwood (Westminster), chairman of committee, presided at the business meeting, his place being afterwards taken by the retiring president, Sir Michael Foster, K.C.B. The honorary secretary, Mr. W. A. Shenstone (Clifton), relinquished his post, and the Rev. E. C. Sherwood (Westminster) and Mr. Hugh de Havilland

(Eton) were elected to serve in a joint capacity. Mr. J. Talbot (Harrow) was re-appointed treasurer, and the Rev. the Hon. Canon Lyttelton, headmaster of Eton, was unanimously elected president for the year 1907.

Sir Michael Foster, in opening the conference, excused himself from giving an address on the ground that for some time his mind had been filled with very inferior things (Sir Michael referred to the contest for the representation of London University in Parliament). The first paper was read by the Rev. W. Madeley (Woodbridge); its aim was to invite discussions upon the possibility of introducing a comprehensive syllabus of scientific teaching within the time limits of a classical curriculum. Mr. Madeley characterised the fact that there was no compulsory science on the classical sides of public schools as a deplorable anachronism. He pointed out, too, that philosophy was introduced into the classical honours papers at Oxford, and that classical scholars were expected now to know what was meant by the "struggle for existence," "survival of the fittest," "the Glacial epoch," and "the laws of motion," as shown by questions set in examination papers. He suggested that two hours alone per week could be spared in which classical boys could do science, and outlined a general course of what he termed natural philosophy, which he thought would broaden the outlook of the boys and do more for their general education than a training in some special branch of science. Among the items in his syllabus were gravitation, the solar system, the conservation of energy, the indestructibility of matter, the laws of chemical change and combination, Darwinism and evolution.

Sir Michael Foster, in the discussion which followed, said that he sympathised with the wish of Mr. Madeley, who had given them a problem to solve and mentioned the time in which it had to be done. He went on to say that the whole use of science was dependent upon the habit of mind that was acquired, and this, which meant openness, alertness, and power of observing many things, could not be gained by surveying the whole world of science, but by attendance to details. When these had been mastered broader views and generalisations could more easily be grasped.

Mr. W. D. Eggar (Eton) advocated that the two hours should be devoted to laboratory study, and that a very small bit of science should be thoroughly taken up. No lectures should be given, as the boys could read up notions for themselves. Mr. D. Berridge (Malvern) thought that if classical masters prepared a number of foreign phrases for the science boys to learn, so that those met with in the newspapers could be understood, they would be as well equipped from the literary point of view as Mr. Madeley's boys would be in science by the course which he had outlined. Mr. Berridge agreed that the division of the lower school into classical and modern sides militated against the taking of science on the former of these. He suggested that headmasters should try the experiment of making, say, the five subjects of the old London matriculation compulsory for all boys until they were sixteen years of age and ready to specialise. Mr. W. A. Shenstone (Clifton) asked why boys might not have the special and the general training as well, and advocated, in addition to the two hours' work at a particular branch in the laboratory, the attendance of the boys once a fortnight at general lectures, such as those lay addresses given at Clifton on Sunday evenings. Many speakers emphasised the ignorance of the classical boy and man. Mr. Cumming (Rugby) said that the only instrument that they understood when they left school was the pen.

Mr. J. Talbot (Harrow) read the second paper, on the present state of the Army examinations, and began by alluding to the changes which have recently taken place, not only in the standard and arrangement of subjects, but also in their very nature. As he considered that the changes were permanent, he went on to trace the reason for them. For this we must go to South Africa, for the recent war has altered the whole principles underlying the tactics and training of the Army. As Colonel Henderson has pointed out, the discipline used to be entirely mechanical, killing all individuality, and forbidding either officer or man to move without direct order; now, as he says, soldiers must be like a pack of well trained hounds, not running in regular order, but without stragglers, each using his instincts and intelligence, and following up the general aim with relentless perseverance.

Under the old conditions, Mr. Talbot said, brains were not essential in an officer, and any type of entrance examination would do, and did. Now, however, if each officer is to employ the trained initiative which is essential in the new order of things and produce it in his men, it is obvious that his own training as a boy becomes all important. While Woolwich and Sandhurst supply the purely technical training, the science masters have to supply the mind they train, and this must be well developed, inured to hard work, and, above all things, supple.

We are now in a position, continued Mr. Talbot, to understand the division of the examination into two parts. The qualifying examination, or its equivalent, the leaving certificate, is intended to ensure that the boy has a sound general education, the competitive, that he has brains, and unless the standard of the examination is fairly high it is difficult to discriminate between brains and cram.

One of the chief qualifications of the officer is the power of initiative; he is always meeting fresh problems, the solution of which, right or wrong, must be found quickly, and on its correctness the lives of his men and possibly of a whole army may depend. No method of teaching which Mr. Talbot had found makes more demand on a boy's power of drawing conclusions and acting on them than the practical work in the laboratories. For this reason science should be compulsory in the qualifying examination, though not in the competitive one as it at present stands. Certain things militate against the adoption by candidates of science—the want of laboratory accommodation, the fact that the alternative subject, Latin, can be taught to all the boys at once, and that there are two examinations. In larger schools Mr. Talbot fancied that science is doing well in the struggle for existence. In conclusion, science masters were told that they could no longer grumble at a reactionary War Office; they must see to it that it is not able to talk of antiquated teachers. It would be a bad thing for the schools if there ever arose a military Osborne to supersede the science masters.

Sir Michael Foster bore out what Mr. Talbot had to say about the two halves of the examination. The committee on military education had had to face the fact that many an officer could not spell, and had no knowledge of accounts. The qualifying examination was to ensure that the candidate should at least be able to write a letter, and the competitive to prove that he had brains, and, being able to use them in some directions, might be likely to do the same in others. Subsequent speakers made it clear that many boys at the public schools took science in the qualifying examination if not in the other. The discussion turned afterwards on the difficulties of, and objections to, the practical examinations in science, especially when no examiner came to conduct them. As an alternative, it was suggested that the production of note-books kept in the laboratory to show that the candidate had been through a proper course of training should be accepted in lieu of practical tests, and should determine whether the owner should be allowed to sit at the theoretical examination.

An exhibition of scientific apparatus by various makers and members of the association was arranged in the laboratories of Westminster School in connection with the meeting. Two novelties were shown by Messrs. Brown and Son; the first was a combination of the conical condenser from their "Desideratum" still with a hot water oven, the hot water from the top of the condenser being used to feed the jacket of the oven. The other was a new suction and blast apparatus dependent upon water pressure, which worked almost instantaneously. Among the exhibits of the science masters themselves was a very neat method of rocking a flask or other vessel by placing under one edge of the circular base of the stand supporting it an india-rubber tube through which a current of water is passed. The Rev. E. C. Sherwood exhibited this, and also some exceedingly useful clamps designed by Mr. Barnes. Though adapted for almost any work, those shown were used by Mr. Sherwood on retort stands, and are wonderfully ingenious and effective. A spring prevents the clamp from sliding rapidly down the rod when the screw is released; the tightening of the latter not only fixes it on the

rod, but holds the arm perfectly immovable in any position, three contacts being made. The arm will support any weight that will not actually break it. On some clamps a micrometer screw allows the arm to be moved while supporting the full weight that it can carry. Those who have struggled with the old type of retort stand clamp which wobbles in all possible directions will welcome the new invention should it be put upon the market.

WILFRED MARK WEBB.

THE THIRD TANGANYIKA EXPEDITION.[1]

I LEFT London for Cape Town on March 24, 1904, proceeding thence to Chinde, and up the Zambesi and Shiré Rivers, to Blantyre and Zomba, in British Central Africa. In Zomba I reported myself to Sir Alfred Sharpe, and from him received much advice and assistance before leaving shortly for the Upper Shiré and Lake Nyasa. In the region of this lake I stayed, roughly, three weeks—one week on the gunboat anchored at the south end, one week ascending the lake, and a week in Karonga before starting to cross the plateau to Tanganyika.

I collected, as far as possible in the short time, specimens to illustrate the flora of the lake—dried specimens, algæ scraped from rocks, &c., and tow-nettings containing diatoms and other of the more minute organisms. I made no systematic attempt to collect fish, but brought a few specimens, in addition to some leeches, crabs, a species of prawn (of interest as none had been recorded hitherto from the lake), and a sponge.

Karonga was left on July 5, and after an unavoidable delay on account of illness among my men, I arrived at Niamkolo, at the south end of Tanganyika, on July 27. I made this spot my headquarters for more than two months, though during the period I stayed a week at Kituta. I purchased at once a large dug-out canoe and hired a crew, so that I was able from the first to fish, dredge, and take tow-nettings. Meanwhile, I made arrangements with the owner of a large dau in Ujiji to hire his vessel, and this was dispatched to the south end of the lake to pick me up. I sailed on board the dau on September 23, and for the rest of my time on the lake cruised about, visiting as far as possible the most interesting and likely places on the lake shore. I camped on land whenever circumstances permitted, but my stays varied, according as I found much or little of value to me. Although I made some attempts, I found it almost impossible to dredge satisfactorily in deep water by means of the dau, so I was reduced to dredging from the canoe, in which case, of course, we had not sufficient power to dredge at any depth. On one occasion, by the kindness of the captain, I was permitted to make an attempt from the German gunboat, but unfortunately I lost the dredge and a large part of the rope, by the snapping of the rope under the strain.

I collected fish on every possible occasion, but though we tried various methods of catching them, the majority were obtained direct from the native fishermen. The largest fish I saw was a Siluroid (probably Clarias), 155 cm. in length, and weighing 30·6 kilograms. Tow-nettings were taken systematically at various times before and after dark, in various places and at various seasons. These consisted, as a rule, principally of phyto-plankton, but there were also prawns, copepods, ostracods, and insect larvæ taken in this fashion. The quantity of material obtained by tow-netting became markedly less during the rainy season. The larger representatives of the flora were also collected, but show, on the whole, little difference from the corresponding water-weeds of Nyasa. Scrapings from the rocks and submerged stems of plants produced various of the smaller algæ, while a few fungi were brought from the rotting wood of the canoe.

Five or six species of prawns were collected, in addition to those already known from the lake, some among the rocks at the water's edge, others by dredging in a few fathoms. Some two or three species of crabs were obtained, and at least two species of Argulus. These latter were perhaps most common from the mouth-cavity, gill-bars, and surface of the body of various large Siluroids, but they were also frequently present upon large specimens of Lates, and occasionally on other scaly fishes. Two forms of true parasitic copepods were found—one on the gills of a Siluroid, and the other attached at the junction of the pelvic fins of a Polypterus. Of worms, a few Oligochætes were collected and a considerable number of leeches.

In addition to these were some Turbellaria, and various endo-parasites—Cestoda, Trematoda, and Nematoda—principally from the gut of fishes. Among the Polyzoa is, at any rate, one form with horseshoe-shaped lophophore, which has not yet been described from Tanganyika. There is probably little of interest in the molluscs collected, as my work was confined to the comparatively shallow water. I was struck by the irregularity in the appearance of the Tanganyika medusa, or rather the uncertainty of finding it at any particular time or place. It is doubtless, like all such forms, driven to and fro by wind and currents, but it is curious that one may be a month or more on the lake without seeing a single specimen. I have brought back a few in formalin, for museum purposes, and others preserved with a view to the histology. Some quantity of sponge was collected, encrusting in every case submerged rocks or shells.

Apart from actual collecting, some observations of physical interest were made. Attempts were made, both on Nyasa and Tanganyika, to observe the seiche alterations in water-level, and at the south end of Tanganyika the actual level of the water was marked, with the view of affording some basis of comparison for the use of future investigators. A good many readings of the water temperature have been taken, which should prove interesting, as I believe nothing has ever been recorded from these lakes before. The temperature in general seems very high, the lowest obtained on the lake being only 73°·3, and the highest recorded 81°·0. At a depth of 76 fathoms (length of the sounding-line) the temperature appears fairly constant, for readings taken on various occasions, and at different spots, only vary between 74°·1 and 74°·8.

The total length of time spent on and around Tanganyika was about eight months. Dismissing the dau at Usumbura, at the north end of the lake, I began on March 18, 1905, the journey overland to the western shore of the Victoria Nyanza. This took rather longer than was expected, owing to the bad weather and the famine-stricken nature of the country, but Bukoba, a German station on Nyanza, was reached on April 16. During a stay of ten days waiting for the steamer, and during a short stay in Entebbe, the British capital, I was able to do some collecting in this lake also. As far as possible, representatives of the water flora were obtained, for the sake of comparison with the plants collected on Nyasa and Tanganyika. A few tow-nettings were taken, and, in addition to the smaller plants and animals thus obtained, there were also collected a few molluscs, some Argulus, and certain endo-parasites. More interesting was the finding of a species of prawn and a sponge, as no sponge had been recorded from the lake before.

[1] From a report by Mr. W. A. Cunnington, Christ's College, Cambridge.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE council of King's College, London, has received a donation of 500*l*. from the Drapers' Company for the further equipment of the physics laboratory, especially for the promotion of research.

PROF. W. W. WATTS, F.R.S., assistant professor of geology and professor of geography at the Birmingham University, has been appointed professor of geology at the Royal College of Science, South Kensington, vacant by the retirement of Prof. J. W. Judd, C.B., F.R.S. In view of the changes in organisation that may be found desirable in the Royal College of Science and the Royal School of Mines after the consideration of the report of the departmental committee on the college, the appointment has been made a temporary one.

THE council of the Armstrong College of Durham University in Newcastle has resolved to found a chair of

electrical engineering, and has voted a sum of 260*l.* toward the equipment of electrical engineering laboratories. At the end of the current session two fellowships of 125*l.* a year will be offered for competition, on condition that the holders should spend their time in the prosecution of definite research or in the pursuance of a definite line of advanced study. Mr. H. Morris-Airey, lecturer and demonstrator in physics in the University of Manchester, has been appointed lecturer in physics at the college in succession to Mr. R. J. Patterson.

THE movement for extending higher education in the Potteries has received (says the *Lancet*) a great impetus from the offer by the Duke of Sutherland of Trentham Hall to the Staffordshire County Council for higher educational purposes. For some time a scheme to establish a university college for North Staffordshire has been energetically brought forward, and promises of help have been received from the North Staffordshire Institute of Mining and Mechanical Engineers, from a joint committee of china and earthenware manufacturers, and from various other sources. The scheme commended itself so much to the county council that it offered to contribute 12,500*l.* to the building fund, and to undertake the maintenance of the college. The hall is considered to be in every way admirably adapted for the purposes of a university college.

THE following gifts in aid of higher education have been announced in *Science*. The Pennsylvania College for Women in Pittsburg has succeeded in raising 38,000*l.* to pay off a mortgage resting upon its property, and to make a beginning in securing an endowment. After the mortgage has been paid, the college will possess as the nucleus of an endowment fund the sum of 25,000*l.* Mr. Andrew Carnegie has promised to contribute 10,000*l.* toward the endowment fund of Bates College when 20,000*l.* shall have been raised for the same purpose by friends of the college. The University of Pennsylvania received last month an anonymous gift of 10,000*l.* Lake Forest University has received 12,000l., and the University of Wisconsin a bequest of 2000*l.* by the will of the late Mrs. Fannie Parker Lewis, for the establishment of scholarships for needy young women students.

SIR PHILIP MAGNUS, the new Member of Parliament for the University of London, after the formal announcement of the result, proposed a vote of thanks to the Vice-Chancellor for the manner in which, as returning officer, he had conducted the election. During the course of his remarks, Sir Philip Magnus said that during the last two years he has served on a departmental committee presided over by Mr. Haldane to inquire into the working of the Royal College of Science and Royal School of Mines, in relation to other educational institutions. The report of the committee is settled, and Sir Philip Magnus said he was disclosing no secrets when he announced that, if effect is given to the recommendations, London will before long possess an institution, closely connected with the University, for the higher scientific training, and for the application of science to engineering in all its branches, which will compare favourably with any similar school in Europe or America.

AT the meeting of the Sociological Society on January 22, Prof. R. M. Wenley, of the University of Michigan, read a paper on sociology as an academic subject. Sociology, although taught in all the great universities of the United States, is academically in an experimental stage. Like other new subjects, it has received much criticism as being unsuitable for inclusion in the university curriculum. It is said to lack disciplinary value, and it is urged, moreover, that students come to it without the necessary basis in previous knowledge. Prof. Wenley attaches little importance to the first objection, but admits that the second is of real weight. Answering the question, What ought sociology to be as an academic subject? Dr. Wenley suggested that at Cambridge it might well form a part of the moral science tripos; at the Scottish universities, it might be attached to the *practical* training of the theological faculty; in London the opportunities for ethnological, linguistic, and economic research are in need of its complementary aid. Wherever ethics, psychology, economics, anthropology, or the various forms of ethnology have a place, sociology is needed as a coordinate discipline. The paper concluded by urging that sociology must be a science conducted by scientifically trained, competent experts, and not merely a pottering-round so-called problems of local or even national origin by well meaning enthusiasts.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 14, 1905.—"On the Distribution of Chlorides in Nerve Cells and Fibres." By Prof. A. B. **Macallum** and Miss M. L. **Menten**. Communicated by Prof. W. D. Halliburton, F.R.S.

At the present day, when numerous observers are seeking the explanation of certain nerve-phenomena on an electrolytic basis, it is imperative that accurate knowledge of the electrolytes present should be first obtained. Prof. Macallum has carried out previous work in this direction, and has discovered methods for detecting the inorganic salts microchemically. He has, among other things, found that nerve cells are destitute of potassium. This element, at any rate, is not revealed by tests which show its presence in other tissues, though it is possible, as Prof. J. S. Macdonald has pointed out, that it may be present in a "masked" form, from which it is liberated by injury. Another reaction at which Macallum has worked is the well known reduction stain with silver nitrate. The staining has been attributed by some histologists to the formation and subsequent reduction in sunlight of a silver-proteid compound. But this cannot be the case, because proteids freed from inorganic salts do not give the reaction. The test is shown to be entirely due to inorganic chlorides, and thus forms a method of great delicacy for the detection and localisation of chlorine in the tissues.

The present paper deals with the distribution of chlorine in the nerve-units. The chlorides present are probably numerous, but sodium chloride is the most abundant. By the ordinary method, nerve fibres exhibit the well known crosses of Ranvier. One limb of the cross is due to the presence of chlorides in the cementing substance which forms a ring at the junction of the neurilemmal elements. The other is due to staining of the axis cylinder itself; this usually exhibits itself, not as a continuous dark stain, but as a series of transverse striæ known as Frommann's lines. It is, however, shown that the same appearance can be produced by suitable modifications of manipulation at any portion of an axis cylinder, and that its greater intensity at the nodes is simply due to the fact that at these spots the reagent can penetrate more readily; the sheath of the fibre presents considerable impediment to the passage of the reagent inwards and of chlorides outwards.

The next question that arises is whether Frommann's lines indicate a definite preexisting arrangement of the chlorides in layers, or whether the appearance is an accident explicable on a physical basis. It is quite conclusively shown that the latter explanation is the correct one. The appearance can be most successfully imitated in capillary tubes filled with chromate-holding gelatin or white of egg, and is merely the result of physical processes, as Boehm and Liesegang were the first to point out.

Nerve cells also contain chlorides, but the intensity of the reaction is less, and is usually limited to the peripheral portions of the cell, principally because of the difficulty the reagent has of penetration. The nucleus, however, like other nuclei, is apparently free from chlorides.

The distribution of electrolytes such as sodium chloride in the colloid material of an axis cylinder would not permit ions carrying an electrical charge to travel unimpeded, and in consequence the change of potential transmitted would progress with diminished velocity. This diminution would bring into line as parallel phenomena the nerve impulse and the electrical current of action. It must, however, be freely admitted that caution should be shown in drawing conclusions of this kind where so much is still unknown.

Geological Society, January 4.—Dr. J. E. Marr, F.R.S., president, in the chair.—The highest Silurian rocks of the Ludlow district: Miss G. L. **Elles** and Miss I. L. **Slater.** The authors give a classification of the beds, and a brief outline description of the main subdivisions is first given, as they appear when followed from Ludlow southward to Overton, eastward to Caynham Camp, westward to Downton-on-the-Rock, and northward to Bromfield, and also near Onibury and Norton. The main tectonic features of the district appear to be due to the superposition of Armorican movements in rocks with a Caledonian trend, held by some rigid mass to the north, presumably the Longmynd massif.—The Carboniferous rocks at Rush (County Dublin): Dr. C. A. **Matley,** with an account of the faunal succession and correlation: Dr. A. **Vaughan.** Rocks of the Carboniferous Limestone series are exposed along five miles of coast near Rush, Loughshinny, and Skerries, in County Dublin. The present paper deals only with the beds near Rush, in the southern portion of this tract, where about 2500 feet of the series are exposed, without allowing for gaps in the succession. The upward sequence is (on the whole) from south to north, and the range is from the Upper Zaphrentis- to the Upper Dibunophyllum-zone.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 25.

ROYAL SOCIETY, at 4.30.—Experiments on the Chemical Behaviour of Argon and Helium: Dr. W. T. Cooke.—The Vapour Pressure in Equilibrium with Substances holding Varying Amounts of Moisture. Parts I. and II.: Prof. F. T. Trouton, F.R.S., and Miss B. Poole.—Note on Heusler's Magnetic Alloy of Manganese, Aluminium and Copper: Prof. A. Gray, F.R.S.—On the Overstraining of Iron by Tension and Compression: Dr. J. Muir.—On the Effect of High Temperature on Radium Emanation: W. Makower.—Observations and Photographs of Black and Grey Soap Films: H. Stansfield.—Galvanic Cells Produced by the Action of Light. The Chemical Statics and Dynamics of Reversible and Irreversible Systems under the Influence of Light. Second Communication: Dr. M. Wilderman.—Artificial Double Refraction due to Æolotropic Distribution, with Application to Colloidal Solution and Magnetic Fields: T. H. Havelock.—An Electrical Measuring Machine for Engineering Gauges and other Bodies: Dr. P. E. Shaw.—The Relation between the Osmotic Pressure and the Vapour Pressure of a Solution: W. Spens.—The Elliptic Integral in Electromagnetic Theory: Prof. A. G. Greenhill, F.R.S.—On the Simple Group of Order 25920: Prof. W. Burnside, F.R.S.—On Metallic Reflection and the Influence of the Layer of Transition: Prof. R. C. Maclaurin.

SOCIETY OF ARTS, at 8.—High Speed Electric Machinery, with Special Reference to Steam Turbine Machines: Prof. S. P. Thompson, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Technical Considerations in Electric Railway Engineering: F. W. Carter.

FRIDAY, JANUARY 26.

PHYSICAL SOCIETY, at 5.—The Isothermal Distillation of Nitrogen and Oxygen and of Argon and Oxygen: I. K. Inglis.—On the use of Chilled Cast Iron for Permanent Magnets: A. Campbell.—Experiments on the Propagation of Longitudinal Waves of Magnetic Flux along Iron Wires and Rods: Prof. T. R. Lyle and J. M. Baldwin.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Prince of Wales Pier, Falmouth: T. R. Grigson.—Ferro-Concrete Pier at Purfleet: H. O. H. Etheridge.

SATURDAY, JANUARY 27.

THE ESSEX FIELD CLUB (at Essex Museum of Natural History, Stratford), at 6.30.—Methods of Fire-making, Ancient and Modern—A Lecture and Demonstration: Miller Christy.

MONDAY, JANUARY 29.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—The Geographical Functions of Certain Water Plants in Chile: Prof. G. F. Scott Elliot.

SOCIETY OF ARTS, at 8.—Modern Warships: Sir William White, K.C.B., F.R.S.

INSTITUTE OF ACTUARIES, at 5.—The Variations in Masculinity under Different Conditions: J. N. Lewis and Dr. C. J. Lewis.

TUESDAY, JANUARY 30.

ROYAL INSTITUTION, at 5.—Impressions of Travel in China and the Far East: Prof. E. H. Parker.

SOCIETY OF ARTS, at 8.—The Chemistry of Artists' Colours in Relation to their Composition and Permanency: Prof. J. M. Thomson, F.R.S.

FARADAY SOCIETY, at 8.—The Electric Furnace: its Origin, Transformations and Applications. Part III.: Adolphe Minet.—Demonstration of a New Electrolytic Tube Furnace: Dr. J. A. Harker.—Note on the Production of Ozone by Electrolysis of Alkali Fluorides: E. B. R. Prideaux.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Railway-Gauges of India: F. R. Upcott.

WEDNESDAY, JANUARY 31.

ROYAL GEOGRAPHICAL SOCIETY (Research Department), at 5.—Suggestions as to an Inquiry into the Resources of the British Empire: Prof. G. F. Scott Elliot.

THURSDAY, FEBRUARY 1.

ROYAL SOCIETY, at 4.30.—*Probable Papers:* On the Filtration of Crystalloids and Colloids through Gelatin, with Special Reference to the Behaviour of Hæmolysins: J. A. Craw.—Chemical Action of *Bacillus lactis aerogenes* (Escherich) on Glucose and Mannitol. Production of 2:3-Butyleneglycol and Acetylmethylcarbinol: Dr. A. Harden and G. S. Walpole.—On Voges and Proskauer's Reaction for Certain Bacteria: Dr. A. Harden.—The Quantitative Estimation of Small Quantities of Nickel in Organic Substances: H. W. Armit and Dr. A. Harden.—The Alcoholic Ferment of Yeast Juice: Dr. A. Harden and W. J. Young.—On the Function of Silica in the Nutrition of Cereals. Part I.: A. D. Hall and C. G. T. Morison.

CHEMICAL SOCIETY, at 8.30.—Hydroxylamine-$\alpha\beta$-disulphonates (Structural Isomerides of Hydroxyamino-sulphates or Hydroxylamine-$\beta\beta$-disulphonates): T. Haga.—Studies in the Camphane Series. Part XXI. Benzenediazo-ψ-Semicarbazino-camphor and its Derivatives: M. O. Forster.—The Relation between Absorption Spectra and Chemical Constitution. Part I. The Chemical Reactivity of the Carbonyl Group: A. W. Stewart and E. C. C. Baly.—(1) The Relation between Absorption Spectra and Chemical Constitution. Part II. The Quinones and α-Diketones; (2) The Relation between Absorption Spectra and Chemical Constitution. Part III. The Nitranilines and the Nitrophenols: E. C. C. Baly and A. W. Stewart.—The Action of Light on Benzylidenephenylhydrazine: F. D. Chattaway.—The Union of Chlorine and Hydrogen: D. L. Chapman and C. H. Burgess.—Note on the Molecular Weight of Adrenaline: G. Barger and A. J. Ewins.—The Critical Temperature and Value of ML/O of Some Carbon Compounds: J. Campbell Brown.

ROYAL INSTITUTION, at 5.—The Significance of the Future in the Theory of Evolution: Benjamin Kidd.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Destructor Bye-products: F. L. Watson.

LINNEAN SOCIETY, at 8.—The Percy Sladen Trust Expedition to the Indian Ocean in H.M.S. *Sealark*: J. Stanley Gardiner.

THE PHILOSOPHIC FOUNDATIONS OF SCIENCE.

Science and Hypothesis. By Prof. H. Poincaré. Pp. xxvii + 244. (London: The Walter Scott Publishing Co., 1905.) Price 3*s.* 6*d.*

Wissenschaft und Hypothese. By Prof. H. Poincaré. Autorisierte deutsche Ausgabe. Translated by F. and L. Lindemann. Pp. xvi + 342. (Leipzig: Teubner, 1904.) Price 4.80 marks.

A SCIENTIFIC man, while actively engaged in work of research, must have faith in the solidity of the foundations on which he builds his reasoning in order to preserve the persistent patience which is necessary if his work is to be successful. Were he to doubt that there are laws which cannot be broken, were he to examine critically every brick in his foundation in order to discover some secret flaw which might endanger the safety of his edifice, he would become a philosopher, but as a man of science he would go to swell the ranks of the unemployed. Nevertheless, we must assign a proper place in the history of scientific thought to the spirit of scepticism which throws doubt on the premises, has no faith in the reasoning, and only grudgingly concedes the conclusions. If I have qualified the statement contained in the opening sentence and confined its application to the time a man is actively engaged in scientific work, it is because there are periods in every man's life when it is good for him to dig down to the bottom of his beliefs. Nor will the critical examination of axioms and definitions be without profit; for it will tend to loosen the ties of preconceived notions which keep men of science, like other mortals, in bondage.

The special difficulty of inquiring into the laws which form the basis of our scientific beliefs consists in the fact that it is apt to lead us round in a circle. When we have tried to formulate a law of nature, we often discover that we have only defined a scientific term. A superficial mind, satisfied with this discovery, would proclaim that all science resolves itself into definitions and conventions, but a closer examination exposes the shallowness of such a conclusion. If among a number of possible definitions we choose a particular one, there must be a deeper meaning in the propriety of the choice. Even though a law may be of our own making, to use Prof. Poincaré's descriptive language, "our decrees are those of an absolute but wise ruler who consults his Council of State." The inquiry into a law of nature resolves itself, therefore, into an inquiry why that particular law is more convenient than others that can be imagined, but this conclusion only brings us back to our starting point, the question as to the truth of a law and its convenience being identical.

Prof. Poincaré's volume will come as a revelation to many who have thought but little about these matters, and as a relief to others who have attempted without success to arrive unaided at a conclusion satisfactory to themselves. But the book requires close and careful study, and a superficial gleaning of its contents would probably lead to mental disaster. For, even following Prof. Poincaré's guidance, we feel ourselves all the time walking along a precipice, at the bottom of which is written, "You shall never know anything of the real construction of the material universe." The author seems to enjoy taking us very near the edge of that pit, and when he whispers into our ears, "what you cannot know is not worth knowing," we feel as if he intended to throw us over. But he has a sense of humour which saves him and us, and there is always a solution which we should perhaps have rejected at first sight, but which we are glad to accept after a contemplation of the less cheerful alternatives which have been brought into our view. There is certainly no one with the same intimate knowledge of mathematical and physical science who could have written with the same authority and produced a volume in which so much charm and originality are condensed. The wealth of his store of illustration is boundless, and the stringency of his logic leaves us without answer. Even in cases when our instincts rebel, we are carried away by the fascination of the language, which in each subdivision of the subject takes us with dramatic power to its artistic *dénouement*.

Could and should such a book be translated? The fascination of the original can certainly never be reached, but translation is allowable where the main argument can be reproduced without loss of clearness, though the delicacies of meaning to which the French language peculiarly adapts itself will undoubtedly be lost.

The English translation errs, perhaps, on the side of following too literally every sentence, and sometimes even every word in the sentences, of the French original. The meaning of the text is carefully though often awkwardly preserved. While the reader is not carried away by the incisive character of expression which belongs to the original, he will in most cases be able to re-construct the dominant idea. The German translation is more successful. We must ascribe this in the first place to the fact that one of the translators has himself made important contributions to certain parts of the subject, and, feeling himself secure in apprehending the meaning, has been able to reproduce the sense without putting any strain on the language. The result is that, while no one could read a few pages of the English edition without recognising the fact that it is a translation, the German carries with it much more of the freshness of an original book. The German translator is also to be commended for the addition of a good index. A series of notes is added, which take up a considerable fraction of the whole volume. Many of these notes will be useful, as they supply references to writings where the readers can study in greater detail important points on which Prof. Poincaré only touches with a passing allusion. But I cannot refrain from criticising the introduction of controversial matter. Differences of opinion between Sophus Lie and Prof. Lindeman are surely out of place in the translation of a book of this nature.

It is time to refer more particularly to the contents of the book. The volume opens with a chapter on the nature of mathematical reasoning, which is shown to be contained in a power of generalisation dependent on recurrent reasoning. When we have proved a theorem for one number, and show that if true for any number a, it is also true for a number $a+1$, we may assert it to be true for *all* numbers. This is the generalisation which, according to Poincaré, lies at the bottom of all mathematical argument, and allows us to pass from the finite to the infinite. The second chapter brings mathematical quantities into relationship with experiment, and treats, among other things, of incommensurable quantities and the creation of the physical and mathematical continuum. We are made to understand how, adopting a certain definition of a line which would satisfy most of us, the diagonal and inscribed circle of a square have no point in common, and we are then asked to admit the possibility of a curve which has no tangent. But a greater surprise is in store for us in the second portion of the book, where, in the course of an admirable discussion of the geometries of Lowatchewski and Riemann, we are introduced to the possibility of a fourth geometry, in which a right line may be at right angles to itself. This part of the book will probably be the one most valued by the student of experimental science, because it deals with an aspect of the subject which, though foreign to his customary plane of thought, must be of the highest interest if he desires to dip a little below the surface.

The conception of space and the relation of geometry to experiment are discussed briefly, but with great precision and clearness. The foundations of geometry are shown to be experimental. "If there were no solid bodies in nature, there would be no geometry." Yet, though founded on experiment, the laws of Euclidean geometry can never be upset by experiment:

"If, then, to contemplate the impossible, one were to discover negative parallaxes, or to find that all parallaxes lie above a certain limit, one would have the choice between two conclusions: We might reject the Euclidean geometry or, on the other hand, we might modify the laws of optics by admitting that light is not accurately propagated in straight lines. It is unnecessary to add that everybody would choose the latter alternative as most convenient."

The final conclusion is that "geometry is not true: it is convenient."

More than one-third of the book having been taken up with the discussion of the fundamental notions of mathematics, we are fully equipped to enter into the discussions of the laws more particularly associated with physics. All those who care to think of these matters at all must have given some attention to the nature of the so-called laws of motion. They will find much in Prof. Poincaré's reflections that has been familiar to them, and something, perhaps, that they have vaguely felt, but not been able to put into definite form. One point which is brought out clearly, which, speaking for myself, I had not sufficiently realised, consists in the difficulty of finding independent measures of both force and mass unless the third law of motion is treated as an axiom. The discussion of the third law will be found to be full of interest. Too little importance, perhaps, is attached to what the author calls "anthropomorphic mechanics." This is surprising, as anthropomorphic ideas are used by him so freely and convincingly in his foundation of geometrical laws. It is true enough that no one has yet been able to find a scientific basis of mechanics in an anthropomorphic conception of force, but at the same time I do not believe that anyone has ever truly reasoned about force without such idea forming the real moving spring of his thoughts. "One could not maintain," Prof. Poincaré says, "that the sun is conscious of a muscular effort when he attracts the earth." That is true enough, but we are able in our imagination to attach the idea of muscular effort to every effect of force in the same way as we can feel sympathetic pain for a friend who lies on the operating table, though our reason tells us that he himself is quite unconscious of pain. In that case we project our own sensitive and conscious mind into his unsensitive body, and to some extent feel the operator's knife. There are probably great differences in the way different brains work, but I could not myself form an idea of the mechanics of the solar system without imagining myself at its centre and consciously pulling the planets towards me. In the same way, if I imagine myself freely placed in space, I at once become conscious of a pull towards the sun. That anthropomorphism has played an important part in the history of mechanics is admitted by the author, but he restricts the philosophy of science to the discussion of the symbols which can be reduced to measurement.

Prof. Poincaré's discussion of the principles of the conservation of energy will be read with interest. That principle has been abused by energy specialists in a manner which could not fail to call forth a wholesome reaction. The weak point which Prof. Poincaré specially exposes seems, however, to me to touch not so much the enunciation of the principle as the difficulty of identifying potential and kinetic energies in cases where the mechanism of the phenomena is unknown to us. This only means that science is not sufficiently advanced to specify completely the different forms of energy. This most of us admit, while the Energetiker deliberately uses the principle of energy for the purpose of hiding his ignorance. Thermodynamics is briefly dwelt upon, but we should have liked to hear more of the author's views on the dissipation of energy. The far-reaching consequences of the gradual decay of regular motion assign to the second law of thermodynamics a predominant place, and put the importance of the first law completely into shade. Lord Kelvin's principle of dissipation of energy has opened out a common ground lying on the borderland between physics and metaphysics which has not been cultivated so much as it deserves to be.

It is not possible to follow Prof. Poincaré in his discussions of selected questions of modern theories of physics. They will be read with interest, though

many of us will not agree that "a day will come when the ether will be rejected as useless."

The reader will place the book—if possible the original, but *faute de mieux* its translation—on his shelves with the intention of frequently spending an instructive quarter of an hour with it. Each time he carries out his intention he will realise more the truth of the author's remark: "To doubt everything or to believe everything are equally convenient solutions: both absolve us from the necessity of thinking."

Arthur Schuster.

THE INTELLIGENCE OF ANIMALS.

Comparative Studies in the Psychology of Ants and of Higher Animals. By E. Wassmann, S.J. Pp. x+200. (St. Louis, Mo., and Freiburg: B. Herder; London: Sands and Co., 1905.) Price 4*s.* 6*d.* net.

AMONG those who have most carefully and successfully studied the habits and psychology of ants, Father Wassmann occupies a place in the front rank. He has especially devoted his attention to the curious and complicated relations which exist between ants and their domestic animals. Of these, he gives a list comprising no less than 1246 species! Father Wassmann is an accurate and careful observer, and his writings are most interesting.

To show how conscientiously he has studied the ants of his own district I may mention that he made a census of the ants' nests round his home. Many communities have more than one nest. Of *Formica sanguinea*, which he regards as the most gifted of European ants, he records 2000 nests belonging to 410 communities! Most of them have separate summer and winter nests, or rather nests for warm and dry, or cold and wet seasons.

Father Wassmann is by no means one of those who regard ants as exquisite automatons, "devoid even of the simplest sensitive perception and cognition." I quite concur with him—indeed, I expressed the same opinion nearly fifty years ago that "the life of ants is the climax of development in instinctive life throughout the animal kingdom"; and that "the chasm between the psychic life of animals and that of man, is, in many respects, wider between ape and man, than between ant and man."

Father Wassmann is also, I believe, quite correct in alleging that Buechner and Brehm, and even Romanes, have accepted many statements implying intelligence on the part of animals for which there was no sufficient evidence, some of which, indeed, were quite absurd; and, secondly, that they have in some cases built upon them conclusions for which there is no foundation, and which will not stand the test of critical examination.

On the other hand, I am unable to follow him when he altogether denies to ants any, even the most exiguous, rudiments of intelligence. As in the cases of Darwin and Forel, the conclusion forced upon me has been that animals, and especially ants, do possess some elements of intelligence. In that we agree with the vast majority of those who have studied dogs, elephants, &c.

Father Wassmann defines intelligence as "the power of acting with deliberation and self-consciousness, of inventing new means for attaining various purposes and thus making progress in civilisation." But if ants are descended from an original common stock in bygone times, no one will deny that they have "invented new means for attaining various purposes and thus making progress in civilisation." Moreover, even now we see them adapting themselves to the circumstances of their complex life in a manner which it is surely an abuse of terms to call "instinctive." He admits that the observations of all who have studied ants conclusively demonstrate that ants are not mere reflex machines, but beings endowed with sensitive cognition and appetite, and with the power of employing in the most various manner their innate, instinctive faculties and abilities under the influence of different sense-perceptions. Surely, then, under his definition it is impossible to deny that they have some intelligence.

For instance, in constructing their nests, as Father Wassmann admits, ants do not "cooperate with the regularity of a machine or according to a rigid pattern, but each ant with evident liberty follows her own impulse and her own plan. . . ."

"As a rule the most zealous and skilful worker is imitated most; her zeal is catching, so that she directs the activity of the others into the same channel."

Indeed, Father Wassmann's fairness and love of truth compel him to make several candid admissions which seem fatal to his position. For instance, an Algerian ant (*Myrmecocystus altisquamis*) has wide open entrances to the nest. A colony, however, which Forel brought to Switzerland, being much annoyed by the attacks of *Tetramorium caespitum*, gradually contracted the doorways. On this Father Wassmann admits that, "as Forel says, these facts afford irrefutable evidence of the great plasticity of ant instinct. For, this instinct is not merely a nervous mechanism forced to operate along uniform lines; it includes sensitive cognition and appetite, which are not only of an organic but also of a psychic nature."

Again, "within these limits, however, we find a wonderful adaptation of means to the end, and at times a marvellous sagacity of animal instinct, which appears nowhere else to such advantage."

"This phenomenon manifests the marvellous sagacity and quasi-intelligent plasticity of animal instinct, which can hardly be styled 'automatism.' Neither can it be identified with intelligence properly so-called, for this would suppose rational knowledge of the internal laws governing the growth of the ant organism, a knowledge far surpassing even the intelligence of man and entirely beyond the reflections and experience of ants."

Surely, however, if ants have sagacity they must have intelligence. Nor is the attribution to them of "sagacity" an isolated case. Again on p. 157 he says:—

"Their sagacity is instinctive, essentially different from intelligence and reflection. Ants are in their every action guided directly by sensitive perceptions, not by intellectual ideas. The enigma, therefore, is

satisfactorily explained by the innate adaptation of their sensitive cognition and appetite, whereas the hypothesis of animal intelligence is unable to offer any solution."

"Instinctive sagacity" seems to me, I confess, a contradiction in terms.

I admit that the subject is one of much difficulty, but if an ant applied Father Wassmann's rigorous criticism to man himself, I am not sure that our boasted gift of reason could be absolutely proved.

No doubt animals do stupid things, but so do we.

Father Wassmann describes what he justly calls the "lovely scenes" in an ant's nest—the care of the young, the "motherly tenderness" shown to the delicate pupæ—but denies that this is any evidence of affection, and contrasts it with the love of a woman or a man for their children. This, he maintains, "is a *rational* love, *conscious of duty* (the italics are his), therefore it is the highest and noblest love existing in Nature." Far be it from me to say a word against either reason or duty. They are amongst the highest qualities of our nature; but surely they have nothing to do with the love we feel for our children, which rests on even nobler feelings.

While fully recognising, then, the accuracy and interest of Father Wassmann's observations, and after carefully considering his arguments, I cannot but recognise in animals some vestiges and glimmerings of intelligence, and maintain, as I did thirty years ago, that "when we see an ant-hill, tenanted by thousands of industrious inhabitants, excavating chambers, forming tunnels, making roads, guarding their home, gathering food, feeding the young, tending their domestic animals—each one fulfilling its duties industriously, and without confusion—it is difficult altogether to deny to them the gift of reason; and the preceding observations tend to confirm the opinion that their mental powers differ from those of men, not so much in kind as in degree."

AVEBURY.

MAXWELL'S THEORY OF LIGHT.

The Electromagnetic Theory of Light. By Dr. C. E. Curry. Part i. Pp. xv+400. (London: Macmillan and Co., Ltd., 1905.) Price *12s.* net.

DR. CURRY bases his work, which is almost entirely analytical, on Maxwell's equations of the electromagnetic field. These equations suffice to account for the phenomena of electromagnetism, and the book is a discussion of the properties of electromagnetic waves in which the condition that the wavelength is short is generally, but by no means always, introduced. In these equations four vectors are concerned, the electric and magnetic forces, and the electric and magnetic displacements, or, as Dr. Curry prefers to call them, the electric and magnetic moments. The type of equation satisfied by each of these vectors is the same, and it is not necessary for Dr. Curry's purpose to identify the light vector definitely with either. It is another vector satisfying an equation of the same type.

No attempt is made to give a mechanical account of the properties of the ether; it is a medium in which transverse waves of electric and magnetic force are propagated according to the laws indicated by Maxwell's equations; in a crystal, however, of course the direction of the electric force does not lie in the wave-front; the same is true of the magnetic force if the permeability be a function of the direction.

Working on these lines, Dr. Curry has put together a large amount of information as to the analytical properties of such waves. The earlier chapters are entirely taken up with the discussion of the forms defined by certain particular solutions of the equations of motion, for if $\phi \equiv f(r \pm vt)/r$ be a solution, so is $d^n\phi/dx^\lambda dy^\mu dz^\nu$, where $n = \lambda + \mu + \nu$. Some of the solutions thus obtained are of importance in the theory of light, but, as the author states, their interest is chiefly theoretical; and one of his "chief reasons for the elaborate treatment of this particular class of waves has been to indicate another fertile field of research offered by Maxwell's equations."

In chapter iv. we are introduced to the phenomena of interference, treated at first in a simple manner, but applied later to the various kinds of waves the properties of which have already been discussed. The more usual problems of optics first become prominent in chapter v., which deals in the ordinary way with Huyghens's principle and its application to the rectilinear propagation of light. The first difficulty occurs in the attempt to find an expression for the secondary disturbance transmitted from a given element of a primary wave. Such expression may clearly involve the angle ϕ between the normal to the wave and the direction in which the secondary disturbance is being estimated, but the statement that "it is natural to assume that the law of variation of the light vector . . . be according to the cosine of the obliquity of the angle ϕ" is not very convincing, and there seems no reason for calling this law the "natural law of obliquity." The law is, of course, a simple one, and it allows of the analytical solution of various problems which are hardly tractable when a more complex law is assumed; but this is its sole merit. Stokes showed that the true factor is $(1 + \cos \phi)$, and this law is utilised later on; but the physical reason for the change of phase in consequence of which the secondary disturbance from a wave $\sin k(vt - r)$ becomes proportional to $\cos k(vt - r)$ is not discussed as fully as its importance deserves. On these points, reference might with advantage have been made to Prof. Schuster's article in the *Philosophical Magazine*, vol. xxxi.—it is quoted later on another point—or to Lord Rayleigh's article in the "Encyclopædia Britannica." Following this a rigorous proof of Huyghens's principle is given in the usual way from the consideration of the relations existing between certain volume and surface integrals, and the result is applied to optical problems; but the fact that this rigorous analysis leads to Stokes's law of obliquity is not definitely stated, though it follows at once from the formulæ on p. 176.

Diffraction phenomena are explained by the use of the same principles, employing the most general formula for the secondary disturbance, and assuming

that the disturbance is zero over the opaque portion of the diffracting screen, while over the transparent portion it has the same value as though the screen were absent. The results are applied to the problem of diffraction by a straight edge leading to Fresnel's integrals and the properties of Cornu's spiral. These might have been obtained more simply, though the rigorous method has its advantages in enabling one to see the meaning of the various simplifications introduced in the process. Later on in the discussion an interesting account of Sommerfeld's theory is given.

The latter part of the book is taken up with the usual theory of reflection and refraction and of double refraction. The surface conditions are deduced from the electromagnetic equations, and the relations between the incident reflected and refracted vectors follow readily. Attention is directed to the fact that the laws thus deduced do not hold for light, and the effect of a transition layer is considered in a satisfactory manner.

In the last chapter we have the equations relating to the propagation, reflection, and refraction of electromagnetic waves by crystals.

At present, part i. only of the whole treatise is under consideration. This deals, as will have been observed, with the analytical portions of the subject for which Maxwell's theory gives a satisfactory explanation. In part ii. the author hopes to consider the really more interesting portions where the simple Maxwell theory needs modifications before it will fit the facts. Readers will await with interest Dr. Curry's treatment of the phenomena of the rotation of the plane of polarisation, absorption, metallic reflection, the Zeeman effect, and the relations generally between magnetism and light.

INDIAN HERMIT CRABS.

Catalogue of the Indian Decapod Crustacea in the Collection of the Indian Museum. Part ii., *Anomura.* Fasciculus i., *Pagurides.* By A. Alcock, M.B., LL.D., F.R.S., C.I.E. (Calcutta: Indian Museum, 1905.) Price 14 rupees.

THE second instalment of Dr. Alcock's fine "Catalogue of the Indian Decapod Crustacea" is now before us. It deals with the hermit crabs (Paguridea or Pagurides), and forms the first fascicule of the second part, which is devoted to the Anomura. Dr. Alcock is thus making use of the old classification of the Decapoda into Brachyura, Anomura, and Macrura, a course to which modern opinion seems to incline—and, as we think, rightly—in spite of the many merits of Boas's arrangement of the group under the suborders Reptantia and Natantia. In the hands of different authors, the limits of the Anomura have varied considerably, and Dr. Alcock takes the term in the sense of Boas's Anomura, including under it the Paguridea, Galatheidea, and Hippidea only. Now there can be no question that Boas was right in excluding the sponge crabs (Dromiacea) and sand crabs (Oxystomata) from the Anomura when he formed his tribe Anomala, but we believe that the group thus constituted is still an imperfect one, in that it is not true to genealogy, since it omits the Thalassinidea, which are certainly more nearly akin to the primitive hermit crabs than they are to the lobsters, near which they are generally placed. This is not denied by Dr. Alcock, but he gives as his reason for taking the old course with the Thalassinidea that to include them with the Anomura "is going too far, as being likely to confuse the systematist"—a poor compliment to the systematist! A zoological classification must be one of two things—either purely empirical, or based on genealogical facts so far as we can ascertain them, though no one is likely to choose the former alternative at this time of day—but in either case illogical concessions to supposed infirmities of the human intellect do not seem to us to be admissible. However, authorities will never agree on questions of classification, and we do not regard the author's decision as a serious blemish on this otherwise wholly admirable work.

In this volume, as in that on the Indian crabs, Dr. Alcock starts with an introduction on the group as a whole, in which he has condensed into a few pages a great deal of very interesting and useful information. In the tables of distribution which follow it appears that the littoral forms are generally Indo-Pacific in range, but that the more primitive sublittoral genera have a very distinct circumtropical distribution. The bearing of this fact on geographical problems is, of course, an important one. The bulk of the work is taken up with systematic descriptions, which are as excellent as is all Dr. Alcock's work in this line, and deal with some ninety species of twenty-eight genera. At the end of the volume is a "table of the genera and species of Pagurides," with bibliographical references, which must have been extremely laborious to compile, but will now be correspondingly helpful to systematists. The illustrations are excellent.

L. A. B.

OUR BOOK SHELF.

Traditions of the Caddo. Collected under the auspices of the Carnegie Institution of Washington by George A. Dorsey, Curator of Anthropology, Field Columbian Museum. Pp. 136. (Washington, D.C.: Carnegie Institution, 1905.)

The make-up of this volume is somewhat curious. It contains one hundred and one pages of texts, followed by twenty-eight pages of abstracts of the same in small type; there is no index, and the only notes are almost monosyllabic, for they merely indicate by whom the story was told—a fact of little value, inasmuch as we learn absolutely nothing of the narrator beyond his (or her) name. This is the more regrettable, as the Caddo, a tribe allied to the Pawnee and Arikara and associated more especially with the Wichita, has retained none of its ancient culture, and we must therefore know the history of the tribe and of the individual narrators before we can judge of the influences that have gone to shape their stock of folk-tales. Equally regrettable is the absence of notes on the stories themselves; it is true that native names are translated, but there are many points on which the editor could throw light with advantage; for example, in tale 35 we find a dead man cannot get into Spirit Land because he cannot fit his arrows to his bow-string, which has a knot in it; a living man puts in

a new bow-string; the ghost shoots arrows in the air and goes up with them.

For those who are interested in these *märchen*, less for the light they may throw on the problem of diffusion than for the evidence they contain of the beliefs and customs of the Caddo, the usefulness of the work is diminished both by the absence of notes and the lack of an index. For European readers, at any rate, there is a further desideratum, viz. some account of the tribe the tales of which are here collected; the American Folklore Society has set a good example in this respect in the volume of Skide Pawnee tales.

The seventy tales in the present volume, which is to be followed by others on the allied tribes, are largely concerned with the adventures of Coyote and other animals. The first ten are either cosmogonic or deal with origins of various kinds; we have the familiar story of the way in which death was introduced into the world, in this case by Coyote; the deluge legend is probably late, as the flood is sent as a punishment; in a parallel story the destructive animals, which lived at the beginning of the world, are destroyed by fire, mankind being saved by climbing up a rope made on earth and made fast to the sky by Crow. More familiar is the tale of the hare and the tortoise, here told by Coyote and Turtle; in these tales the distinguishing characteristic of the former is his stupidity.

Meccanica Razionale. By Roberto Marcolongo. Vol. i., Kinematics—Statics, pp. xii + 270; vol. ii., Dynamics—Principles of Hydromechanics, pp. vi + 126. (Milan: Ulrico Hoepli, 1905.) Price 3 lire each volume.

No better proof could be adduced of the general and popular interest taken in higher mathematics in countries outside Great Britain than the excellent series of manuals emanating from the firm of Hoepli in Milan. One great difficulty in acquiring a *general* knowledge of such subjects as analytical statics, particle and rigid dynamics, and hydrodynamics arises from the voluminous character of the principal treatises available as text-books. Most of the English standard works on such subjects were originally smallish single volumes, but they have in the course of various editions grown in size until they have reached to two large and bulky volumes. Anyone who can read Italian can now, at a cost of five shillings, obtain in Prof. Marcolongo's two little manuals a survey of such subjects as vector analysis, polhodes and herpolhodes, the ordinary and spherical catenary, planetary motion, Lagrange's equations, the theory of least action, cycloidal and compound pendulums, attractions of ellipsoids, Lagrange's and Euler's equations of hydrodynamics, and the principles of vortex motion.

Die Vererbungslehre in der Biologie. By Dr. H. E. Ziegler. Pp. 74; with 59 figures in the text and 2 plates. (Jena: Gustav Fischer, 1905.)

THIS little work represents a fairly successful effort to put in simple language the complex problems of heredity so far as they have yet been analysed. The author discusses the evidence that cytology has been able to furnish in connection with the theories of variation, and he especially deals with the views of Weismann and of De Vries as to the meaning of variation as expressed in terms of the cell. His attitude towards the mutation theory of De Vries is rendered clear by the following sentence from p. 69, "Wenn man nicht auf dem Standpunkt der 'intracellularen Pangenesis' steht, so kann man nicht einsehen, warum zwischen kleinen und grossen Abänderungen, also zwischen allmählicher und stossweiser Veränderung, eine strenge grenze gezogen werden soll." But the question here raised is not one dependent on theory or hypothesis; it is a question of fact, and the existence of opposite opinions merely demands a more thorough investigation at the hands of persons unbiased by prejudice. Perhaps, as was formerly the case with the inheritance of the so-called "acquired characters," much of the prevalent opposition to the theory of mutation rests on a misunderstanding of the main idea embodied in the word itself.

An Analysis of Human Motive. By F. Carrel. Pp. viii + 222. (London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd., 1905.) Price 5s. net.

THIS volume discusses the six predominant motives which influence man, viz., those of sustenance, sex, pleasure, sympathy, self-love, and religion; examines slightly the conflicts of motives, the relation of motives to moral systems, and the like; and sums up the matter in a series of conclusions which is not entirely destitute of merit.

But the work as a whole is disappointing. The sentences are lumbering and long, sometimes twelve lines long; there are no indications that the author has read very widely, nor is any remarkable insight displayed. Felicitous illustration would have lightened many a page; but of illustration there is almost nothing. The obvious has no terrors for our author, and so the satirical rogue frequently indulges in slanders like the following:—"The pleasure motive may lead persons to pass time in witnessing theatrical performances, and when the taste has been formed and the habit acquired, to spend more of their resources upon such amusements than their means justify." Split infinitives and the use of "practise" as a noun do not lead one to rank the writer as an authority on English. One statement seems defective in mathematical accuracy:—"In provincial towns the proportion of men to women (among church-goers) is twelve to a hundred. In London the proportion is *two-thirds women to one-half men.*" It is difficult to avoid seeing a *non sequitur* in the following:—"The grief experienced at the death of a beloved relative cannot be long continued without interfering with the normal course of life and coming into conflict with its essential motives, and therefore we see that the violent acts of despair to which it tends, are not resorted to as long as the mind has not completely lost its rationality."

We gather that the author thinks much of Epicurus and of Spencer, but little of Aristotle's "Nicomachean Morals," which are, it would seem, of little more than historical interest. The writer continues:—"It was their want of precision that enabled them to be adopted by the schoolmen of the middle ages, as a basis for their ethical dialectics." That Aristotle and this author have very different views of what constitutes precision is true and obvious, but not a circumstance on which this author is to be congratulated.

Deutscher Kamera Almanach, 1906. Second year. Jahrbuch der Amateur-Photographie. By Fritz Loescher. Pp. viii + 280. (Berlin: Gustav Schmidt, 1905.) Price 3.50 marks.

THIS is the second issue of this annual, and from its appearance it seems to be very hardy. The first-named title does not seem very befitting to the volume before us, as the "Almanack" portion is more conspicuous by its absence than presence. As a "Year Book" containing an excellent series of well written articles on numerous photographic subjects by recognised workers in Germany, England, France, &c.; novelties of the year; progress; exhibitions; list of German amateur photographers' societies; most important recent photographic literature, and other useful information, the book will be found of interest to those who are able to read German. The illustrations are good and numerous, and include a frontispiece, 47 full page pictures, and 107 others distributed throughout the text.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Fresnel's Theory of Double Refraction.

THERE is a point in connection with the ordinary expositions of Fresnel's theory of double refraction to which, on account of its frequent occurrence, it is perhaps worth while to direct attention. It is found in Aldis's "Tract on Double Refraction," p. 7, in Preston's "Theory of Light," third edition, p. 328, and in Basset's "Treatise on Physical Optics," p. 115.

Having shown that when a molecule receives a displacement ρ, the other molecules of the system remaining fixed, the restoring force along the line of displacement is $F=\rho/r^2$, where r is the parallel radius-vector of a certain quadric, Preston, for instance, proceeds as follows:—"Hence, if we consider only the component F as effective, the equation of motion of the particle will be

$$d^2\rho/dt^2 = -\rho/r^2 \quad \ldots\ldots \quad (10),$$

and the time of vibration will consequently be given by the equation

$$T = 2\pi r \quad \ldots\ldots\ldots \quad (11).$$

But the velocity of propagation is connected with the wavelength and the periodic time, by the equation $\lambda = vT$, therefore

$$v = \lambda/2\pi r \quad \ldots\ldots\ldots \quad (12)."$$

Now if equation (10) refer to the motion of a particle when the others remain fixed, there is no question of a wave at all, and the deduction of a propagational speed is without meaning; if, on the other hand, we are to regard (10) as giving the motion of a particle in the front of a luminous wave, then equation (11) expresses the bizarre result that the frequency, that is the colour, of the light is dependent upon the direction of vibration.

Fresnel's method was quite different; having determined the value of the restoring force on the supposition of absolute displacements, he employed it for the case of relative displacements, and regarding the component parallel to the wave as alone effective, he *assumed*, on the analogy of the transversal vibrations of a stretched string, that the propagational speed is proportional to the square root of the effective force. Hence, taking the azis of z in the direction of propagation, and making a suitable choice of the unit of mass, we should have in place of (10)

$$\partial^2\rho/\partial t^2 = 1/r^2 \; \partial^2\rho/\partial z^2,$$

giving in place of (12) $v = 1/r$.

One other point may be mentioned. Preston and Basset, quoting from Verdet, state that one of the hypotheses on which Fresnel founded his theory is that the vibrations of polarised light are at right-angles to the plane of polarisation. This is not strictly correct. There is no doubt that this assumption played its part among the ideas that led Fresnel to formulate his theory: in the theory, however, as finally presented, it does not appear as a fundamental hypothesis; it follows, in fact, as a direct *consequence*. On the other hand, the postulate that the ether is incompressible should be included among the hypotheses of Fresnel; indeed, if this be not assumed, the effective component of the force of restitution would have, as Sir G. Stokes has pointed out ("Math. and Phys. Papers," iv., 158), a value quite different from that given by Fresnel.

JAMES WALKER.

Oxford, January 19.

On an Alleged New Monkey from the Cameroons.

I MUCH regret that in describing, in NATURE for October 26 last, the monkey on which I bestowed the name *Cercopithecus crossi*, I overlooked the description of *C. preussi* by Matschie. Dr. Lönnberg, of Stockholm, was kind enough to write me early in November to say that he had "a strong suspicion that your guenon may prove identical with *C. preussi*," described in *Sitz. Ber. Naturforsch. Freunde Berlin* in 1898. Only last week, however, was I able to consult this volume, and there is no doubt that, as Mr. Pocock has now also pointed out, Matschie's name has priority over *C. crossi*.

HENRY O. FORBES.

The Museums, Liverpool, January 27.

FORESTS AND RIVERS.

AT the recent meeting of the International Navigation Congress at Milan, one of the questions taken into consideration was "the influence which the destruction of forests and desiccation of marshes has upon the *régime* and discharge of rivers," and seven papers bearing on the subject were read and discussed. Of these, three were from Austria, and the others from Germany, France, and Russia. The problem as to the effect of forests on the water supply of rivers and on climate is of great social importance on account of the agricultural and commercial interests which are so closely connected with the use of timber, and with the utilisation of running water.

It is allowed by all the authors of these papers that, due to the improvident way in which the forests have been dealt with, there has been a marked change in the water supply of the neighbouring rivers; that where forests have been cut down brooks have disappeared, and many small rivers that at one time were useful as sources of power are so no longer for want of water; that in the larger rivers torrents have become more impetuous, and flooding more frequent; while, on the other hand, navigation suffers at times for want of water.

The greatest harm has been done in the mountain districts, where the steep slopes allow the rain-water to run off too rapidly, carrying away the surface soil and transporting pebbles and boulders into the rivers, causing shoals, and thus decreasing their capacity to discharge the flood water.

The extent to which forests, both on the Continent and in America, are being cut down and destroyed, and large areas of land, which at one time were covered with primæval forest, have become barren waste by fire or the lumberman's axe without any attempt at re-afforestation, was one of the subjects dealt with in the presidential address of Mr. J. C. Hawkshaw at the Institution of Civil Engineers in 1902. Mr. Hawkshaw pointed out that, notwithstanding the displacement of wood in building structures by iron, yet large quantities of timber are still required, not only for building purposes, but for temporary structures, such as coffer dams and scaffolding; pit props for mining; sleepers required for the railways, which, in this country, he estimated at an annual value of 18 million pounds, and those required for renewals at three-quarters of a million pounds; while for the railway service of the United States there are required 15 millions of acres of forest land to maintain a supply of sleepers.

The question for consideration at the Congress was whether the wholesale destruction of forest land for cultivation or for timber supply is having any material effect on the rainfall and consequent water supply; and the effect of forest destruction on the rivers of the country from which the trees are removed was also considered.

The physical conditions of forest land are that, owing to the shelter from sun and wind, the atmosphere is generally colder and damper than in the open country, and evaporation consequently less. It is calculated that a hectare of forest land ($2\frac{1}{2}$ acres) gives off every day 37 cubic metres of oxygen and 37 metres of carbonic acid, leading to a great expenditure of heat; and that from every hectare of forest land sufficient heat is abstracted to melt 316 cubic metres of ice. Ligneous plants also withdraw from the ground and discharge as vapour more than 40,000 gallons of water per hectare per day, which causes a sensible reduction of temperature. When clouds pass over a forest they encounter a cool, damp atmosphere, the point of saturation comes closer, and

rain is caused. This condition of forest land has been remarked on by aëronauts, who find that a balloon is invariably affected, and drops when passing over forests.

The advantages claimed for forests with regard to water supply are that the trees act as regulators of the rainfall; that the average quantity of rain falling on land covered with forests is greater than in the open ground to the extent of about one-sixth; that it holds up the water for a time and discharges it later on when water is most required in river basins, the rain being held back by the leaves of the trees and coming to the ground more gradually; the rain that falls on the surface is also taken up by the layer of dead leaves on the ground, which permits of a gradual percolation to the subsoil. Observations show that in summer the ground of the forest is damper than that of the adjacent cleared land, and snow remains for a much longer period in forest land before melting than in cleared land.

On the other hand, it has been contended by some of those who have made a study of sylviculture that forests do not increase the quantity of water flowing to the springs and rivers, but reduce it. The numerous striking facts quoted do not bear out this contention, which is mainly based on the fact that the substratum water stands at a lower level on forest land than in the adjacent cleared ground. This fact is generally admitted to be the case at one period of the year. As the result of many years' observations, it has been found that the maximum level of underground water is reached in May, that the water accumulates in the ground from August to January; and that the rivers are supplied by this reserve, and were it not for this accumulation many brooks and river feeders would cease to flow in summer.

Several very striking examples are given by the authors of the papers as to the deleterious effect of cutting down forests, especially in hilly districts. In the commune of La Bruguière, the forests on the slopes of the Black Mountain were cut down; the consequence of this removal of the trees was that a brook which ran at the foot, and the water from which was used for driving some fulling mills, became so dried up in summer as no longer to be of any use, while in winter the sudden floods caused very great damage in the valley. The forests were re-planted, and as the trees grew up the water coming to the brook was so regulated as to serve its former useful purpose in driving the mills, and the torrents in winter were moderated. Several other examples of a similar character are given.

In Switzerland, amongst other examples is quoted one that occurred in the canton of Berne, where, owing to the re-planting of the mountain-side with fir trees, the water again appeared at a spring which had ceased to flow. After a period the trees were cut down and the land converted into pasturage, since when the spring has almost disappeared, only opening out at occasional intervals.

In the Kazan district of Russia, once celebrated for its forests of oaks and linden, which are now nearly all cut down, there were formerly seventy water-mills constantly at work. Less than half now can be worked, and even they only run half time, and are idle in summer for want of water; while in winter the little rivers that worked these mills are converted into impetuous torrents, breaking up the mill dams and doing other damage. These abandoned water-mills stand out as a striking proof of the consequences of the destruction of forests.

In Sardinia, where the surface consists of plutonic rocks covered with a thin layer of earth, all the streams have a rapid slope. The woods, which occupied in 1870 an area of more than $2\frac{1}{2}$ million acres, or about 43 per cent. of the whole surface of the island, now are reduced to about one-sixteenth of this area. Since the removal of the trees the floods in the rivers rise with a rapidity and flow with a velocity never known before, and a great number of bridges have been destroyed by the floods. The beds of the channels have been raised in some places above the surface of the land, owing to the detritus brought down in floods.

In Wisconsin, U.S.A., the settlers cut down the forests and converted the land into tillage and pasture. During a period of about seventy years nearly the whole of the forest land was thus cleared, with the result that, as the forest disappeared, the water in the river became lower; finally thirty miles of the channel entirely dried up, and many water-mills that were formerly worked by the stream are now deserted and useless, owing to the want of water to run them.

In Sicily, owing to the cutting down of the forests on a vast scale in the province of Messina, the bed of the river has been raised by the stones and earth carried down by the torrents so as to stop all drainage from the land, and great damage has been done by the floods. Several other examples are given to the same effect where forests have been cleared in the same district, and these are compared with other streams where the forests still exist and their condition remains unaltered. In the former case, landslides from the mountains have become very frequent.

VARIATION OF GLACIERS.[1]

THIS interesting report of the Commission internationale des Glaciers shows that these ice-streams still continue to diminish in those parts of the world which it has been possible to examine. In the Swiss Alps, of ninety glaciers observed, not one shows an advance, which fully confirms the general results of the last seven years, and indicates that any slight variation is now at an end; the same is true of the Italian Alps, though some of them give signs of increase in their upper parts. In the French Alps (Pelvoux district), the Glacier Noir has steadily decreased since 1860; the Glacier Blanc, after decreasing from 1865 to 1886, advanced from about 1889 to 1896, but is now again retiring. It is noteworthy that the average elevation of the supply basin of the former is from 2500 to 2800 metres, and of the latter from 3000 to 3300 metres. In the Savoy Alps the shrinkage continues, some small glaciers having disappeared. The same is true in the Pyrenees.

In Norway both snowfall and temperature were rather variable in 1904, but the glaciers, with a few exceptions, have retreated; and in Greenland the Jakobshavn Glacier has shrunk, sometimes rather considerably. In the Caucasus (central) the glaciers continue to retreat; less is known of the eastern district, but the same apparently is true of it. During the past year M. Fedtchenko visited more than 110 glaciers in the Pamir, and has stated that all appeared to be diminishing. The same is true, with a few exceptions, of the north-western part of the United States, as well as of the mountain region of western Canada. In Africa, though the rainfall had been unusually heavy in the Kilimanjaro district, the amount of snow in the crater of Kibo had not, according to

[1] "Les Variations périodiques des Glaciers." Dixième Rapport, 1904. Rédigé par H. F. Reid et E. Muret (Extrait des *Archives des Sciences physiques et naturelles*, t. xx., juillet et août.) Pp. 34. (Genève: Georg et Cie, 1905.)

Dr. Uhlig, increased since 1901. Thus the report indicates that the retreat of glaciers, which began about forty-five years ago, still continues, having overpowered the slight rally which has been occasionally perceptible during the last decade. T. G. B.

THE REVOLUTION OF THE CORPUSCLE.[1]

Air: "The Interfering Parrot." (*Geisha.*)

A corpuscle once did oscillate so quickly to and fro,
He always raised disturbances wherever he did go.
He struggled hard for freedom against a powerful foe—
An atom—who would not let him go.
The æther trembled at his agitations
In a manner so familiar that I only need to say,
In accordance with Clerk Maxwell's six equations
It tickled people's optics far away.
You can feel the way it's done,
You may trace them as they run—
$d\gamma$ by dy less $d\beta$ by dz is equal $K.dX/dt$.
. . . .
. . . .
While the curl of (X,Y,Z) is the minus d/dt of the vector (a,b,c).

Some professional agitators only holler till they're hoarse,
But this plucky little corpuscle pursued another course,
And finally resorted to electromotive force,
Resorted to electromotive force.
The medium quaked in dread anticipation,
It feared that its equations might be somewhat too abstruse,
And not admit of finite integration
In case the little corpuscle got loose.
For there was a lot of gas
Through which he had to pass,
And in case he was too rash,
There was sure to be a smash,
Resulting in a flash.
Then $d\gamma$ by dy less $d\beta$ by dz would equal $K.dX/dt$.
. . . .
. . . .
While the curl of (X,Y,Z) would be minus d/dt of the vector (a,b,c).

The corpuscle radiated until he had conceived
A plan by which his freedom might be easily achieved,
I'll not go into details for I might not be believed,
Indeed I'm sure I should not be believed.
However, there was one decisive action,
The atom and the corpuscle each made a single charge,
But the atom could not hold him in subjection
Though something like a thousand times as large.
The corpuscle won the day
And in freedom went away
And became a kathode ray.
But his life was rather gay,
And he went at such a rate,
That he ran against a plate;
When the æther saw his fate
Its pulse did palpitate,
And $d\gamma$ by dy less $d\beta$ by dz was equal $K.dX/dt$.
. . . .
. . . .
While the curl of (X,Y,Z) was the minus d/dt of the vector (a,b,c).

[1] Composed by Mr. A. A. Robb and sung at the annual dinner of the research students of the Cavendish Laboratory, Cambridge, on December 6, 1905.

NOTES.

DR. N. L. BRITTON, director of the New York Botanical Garden, has been elected president of the New York Academy of Sciences.

DURING the meeting of the French Association for the Advancement of Science, to be held at Lyons next August, it is proposed, if the suggestion arouses sufficient interest, to arrange an exhibition of urban hygiene.

THE Brussels correspondent of the *Daily Telegraph* states that at the last meeting of the Academy of Science it was announced that Dr. Jacobs had conclusively proved cancer to have a bacterial origin. This is not the first time that similar positive statements have been made which subsequent research has proved to be fallacious, and all such reports must be received with the greatest reserve.

THE Morrison lectures of the Royal College of Surgeons, Edinburgh, have this year been delivered by Dr. Ford Robertson on the pathology of general paralysis of the insane. The main theme of Dr. Robertson's lectures is that general paralysis is an infective or germ disease caused by certain diphtheroid bacilli, which can be isolated from the blood and cerebro-spinal fluid of the patient, and the toxins of which by their action on the central nervous system induce the paralysis and other symptoms.

THE Milroy lectures of the Royal College of Physicians of London will be delivered by Dr. W. H. Hamer on March 1, 6, and 8, the subject being "Epidemic Disease in England: the Evidence of Variability and of Persistency of Type." The Goulstonian lectures will be delivered by Dr. H. Batty Shaw, on the subject of "Autointoxication," on March 13, 15, and 20; the Lumleian lectures by Dr. Ferrier, the subject being "On Tabes Dorsalis," on March 22, 27, and 29; and the Oliver-Sharpey lectures by Dr. E. J. Spriggs on April 3 and 5, the subject being "The Bearing of Metabolism Experiments upon the Treatment of some Diseases." Prof. W. Osler will deliver the Harveian oration on St. Luke's Day, October 18, and Dr. S. J. Sharkey the Bradshaw lecture in November.

THE annual general meeting of the Iron and Steel Institute will be held on Thursday and Friday, May 10–11. The council will shortly proceed to award Carnegie research scholarships, and candidates must apply before February 28. The awards will be announced at the general meeting. In place of the ordinary autumn meeting, a joint meeting of the American Institute of Mining Engineers and of the Iron and Steel Institute will be held in London on July 23–29. The Lord Mayor of London has consented to act as chairman of the London reception committee, and will give a conversazione at the Mansion House on the evening of July 24. The annual dinner will be held at the Hotel Cecil on Friday, July 27. A programme of the visits and excursions to be made during the meeting will be issued when the arrangements are sufficiently matured.

THE death is announced, at the age of eighty-three, of M. Jules Despecher, who for more than half a century played a prominent part in organising and arranging submarine cable services.

THE commission for the methods of examining and methylating alcohol, appointed by the French Government, has decided to offer the following prizes for open competition, irrespective of the nationality of the competitors:—(1) a prize of 20,000 francs for a method of methylating alcohol, which shall be preferable to that now in vogue in France, and which at the same time shall prevent any

defrauding of the revenue; and (2) a prize of 50,000 francs for a system which shall permit of the use of alcohol for illuminating purposes under the same conditions as those for the use of petroleum. Further details and particulars may be obtained from the commission (though not before April), which body will itself decide to whom the awards shall be made.

The programme of the sixth International Congress for Applied Chemistry has recently been issued. The congress will be held in Rome from April 26 to May 3. On April 25 there will be a social gathering of those taking part in the congress, preparatory to the official opening on the following day; on the afternoon of the same there will be the first full committee meeting for the election of next year's officers. On April 27 the sittings of the various sections will begin, and will be continued on April 28 and 30, and on May 1 and 2. For Sunday, April 29, an excursion into the outskirts of Rome has been arranged. On May 3, after the final committee meeting, there will be two excursions, the one to the Island of Elba, and the other to Sicily. During the first, visits will be paid to the iron mines and works of Elba, whilst for the second arrangements have been made for visits to the saltworks of Erapani, the wine factories of Marsala, and the sulphur mines of Messina; but since the two excursions are taking place simultaneously, members of the congress may only participate in one of the two. All members will be entitled to reductions of from 40 per cent. to 60 per cent. on tickets issued by the State railways, according to the distances travelled.

The Philosophical Institute of Canterbury, Christchurch, N.Z., has opened a fund with the object of establishing a memorial to the late Captain F. W. Hutton, F.R.S., president of the New Zealand Institute. It is proposed to devote the fund to the encouragement of original research in natural science in New Zealand by making grants from time to time to persons engaged in original research, and by the award of a bronze medal, to be called the "Hutton medal," for original contributions of special value. In the appeal for support, the memorial committee remarks:—"The influence and importance of research are becoming more and more fully recognised in all parts of the world, but New Zealand has as yet taken no steps for its encouragement, and no financial assistance has so far been given to private workers in any department of science. It is hoped, therefore, that advantage will be widely taken of the present opportunity of contributing to a fund which will encourage research, and will at the same time perpetuate the memory of Captain Hutton, who so unselfishly devoted himself throughout his lifetime to the advancement of natural science in New Zealand." Though the Philosophical Society has taken the matter in hand in order to save time, and has subscribed 50*l*., the board of governors of the New Zealand Institute will probably be asked to take over the work of collecting the funds required. Meanwhile, subscriptions may be sent to Dr. Chilton, Canterbury College, Christchurch, N.Z., who is acting as hon. treasurer of the fund.

From the *British Journal of Photography* (January 26) we read that an international exhibition of photography is to be held this summer at Paris at the Petit Palais, in the Champs Elysées, and will be open from July 16 to October 10. Judging even by the brief statement given, the exhibition will be on a very large scale, there being thirteen groups of exhibits, comprising altogether sixty-three classes. A list of the groups is as follows:—History of photography; applications of photography to science; educational; amateur and pictorial photography; photographic periodicals; professional photography; photographic publications; photographic materials; apparatus and accessories; photo-mechanical processes; industries related to photography; leather dressing; photographic illustrations, and the photographic trade. Such a comprehensive programme will, we hope, bring together workers in all sections, and include a strong British exhibit. In the second group the exhibition is assured the support of a large number of scientific institutions in France and other countries, including the Collège de France, the Museum of Natural History (Paris), the Paris National Observatory, the physiological station at the Parc du Princes, the Marey Institute, the Institute Pasteur, the Faculté de Médecine, the Sorbonne, the School of Pharmacy, the School of Mines, the Smithsonian Institution (Washington), the meteorological observatories of France, and many others. It is stated that the last day for receiving applications for space is fixed for February 25 next, and that an English (?British) committee is in formation. It may finally be stated that no charge is made for exhibits coming under the head of the first three groups.

Among the contents of Nos. 24–27 of the *Sitzungsberichte* of the Royal Academy of Vienna for last year is a notice of Hymenoptera obtained during an expedition to south Arabia, and a summary of the zoological results of another expedition to the Sudan and Gondokoro. In a third paper Mr. A. Handlirsch discusses the phylogeny of the Arthropoda.

In the course of a paper on the natural history of the Warburton district, published in the December (1905) number of the *Victorian Naturalist*, the author mentions that frigate-birds are used in the South Sea Islands as letter-carriers. If captured young, they will return, like homing pigeons, to the island of their birth, and, taking advantage of this trait, the missionaries forward such birds to islands with which they desire to hold communication. When released from their new domicile they fly straight to their old home, where they alight on the identical perches on which they were accustomed to be fed. Later on it is mentioned that diamond-tailed geckos (*Phyllurus platurus*) are always found head-downwards on the rocks they frequent. They assume this position, according to the author, in order to make hawks believe that their heads are their tails; consequently, when seized by one of these birds, which invariably pounce upon what they regard as the head, the brittle tail snaps off, and the gecko wriggles away little or none the worse for the encounter.

We are glad to welcome the volume of the *Zoological Record* for 1904, which from its bulk bears testimony to the energy with which natural history studies are being carried on both in this country and abroad. A few changes have been made in the staff, but in the main the old contributors have remained at their posts. Errors, as usual, appear to be comparatively few, and in many cases are excusable. We notice, however, that the genus Lohmannella (spelt with a single *n*) appears among the mites, as well as (in its proper place) among the Vermes. In the myriopod section, which is written by a foreigner, the editor might well have amended the style of such names as Kaukasus, Wladiwostok, and Eastromelia, while in the Bryozoa he might have noticed that Miss Embleton gives "Memoirs of the Geological Survey of India" as the title of a paper. Again, in the bird section (p. 30) we find the same paper quoted twice over, on account of the fact that it appeared in two different journals. In congratulating the editor and his staff on their successful

labours, we may refer to the fact that they record the appalling total of no less than 2095 new generic and sub-generic names as the result of a single year's work!

IN the *Scientific Reports* of the Imperial Cancer Research Fund (No. 2, 1905) a valuable series of experiments and observations on the growth of cancer under natural and experimental conditions is detailed by Dr. Bashford and his co-workers. The statistical investigation of cancer has also been pursued, and a valuable report is presented. The provisional conclusion is arrived at that there is nothing in the statistical investigations of the Imperial Cancer Research Fund which points to an actual increase in the death-rate from cancer.

IN an interesting article in the *Quarterly Review* (January) Dr. George Pernet reviews the light-treatment of disease, with which the honoured name of the late Dr. Finsen, of Copenhagen, will always be associated. The action of the various rays of the visible and invisible spectrum on the lower forms of life is first detailed, and it is shown that the violet and ultra-violet rays are the active ones, and it is these which are employed for the treatment of lupus. At the same time, it must be recognised that light-treatment has its drawbacks; it is costly, slow in action, and does not influence all forms of the disease, particularly if at all below the surface, since the active rays have little power of penetration. It has recently been observed, however, that if the tissues be first treated with some fluorescent substance, such as eosin, the penetrative powers of the active rays are increased, and this fact may prove to be of practical value. Lastly Dr. Pernet points out that as lupus is a form of tuberculosis, the eradication of the disease is intimately connected with the larger question of the eradication of tuberculosis in general.

A LIST of pyrenomycetous fungi collected in Orleans County, New York, has been prepared by Mr. C. E. Fairman, and is published in vol. iv. of the *Proceedings of the Rochester Academy of Science, U.S.* A number of species are recorded for the first time for the State, and five are new to science.

UNDER the title of "Mesozoic Plants from Korea," Mr. H. Yabe contributes to vol. xx. of the *Journal of the College of Science*, Tokio University, a paper on fossil botany dealing with the collections obtained from a bed of coal shale in the vicinity of Naktong, a village near Sengchu. Twenty-one species, mostly ferns, but including a few cycads and conifers, are distinguished. From the similarity of several of these with species recorded from the Japanese Tetori series, the writer judges that the beds were formed contemporaneously; he also suggests that the plant-bed of Naktong was deposited as a beach formation in shallow brackish water.

IN connection with the fine avenues of trees at Quetta referred to in NATURE of January 11, p. 253, Mr. E. P. Stebbing has been investigating the ravages of a beetle, *Aeolesthes sartus*, that has locally received the name of the "borer." In a pamphlet printed by the Government of India, Mr. Stebbing sketches the salient points in the life-history of the insect. The damage is caused principally by the larvæ, that feed first in the phloem and sap-wood of the tree, and subsequently penetrate during the winter into the heart-wood. The trees that have suffered most have been the Kabul willow, the reamer poplar, and the elm; the walnut, horse-chestnut, ash, and robinia have escaped entirely or nearly so, and, curious to relate, the mulberry has not been attacked.

THE members of the Botanical Society of Edinburgh receive from time to time at their meetings interesting announcements of the discovery of rare plants found during summer excursions. Mr. J. G. Nicolson publishes in vol. xxiii., part i., of the *Transactions and Proceedings* of the Society a list of some rare Caithness plants, that includes *Arctostaphylos alpina*, collected on Mt. Morven, *Hierochloe borealis* from Thurso, and a strange alien, *Hymenaea Courbaril*, known as the West Indian locust, washed up by the Gulf Stream near John-o'-Groats. Mr. W. Young, writing on the plants of the Glenshee district, Perthshire, reports the occurrence of *Gentiana nivalis*, *Veronica alpina*, and *Cochlearia Groenlandica* among flowering plants on or near Glas Maol; among the liverworts gathered in the district were *Cephaloziella Jackii*, *Lophozia socia*, and *Harpanthus Flotowianus*. The volume contains the latest of many papers by Mr. W. West and Prof. G. W. West on algæ, in which they describe the fresh-water algæ collected in the Orkneys and Shetlands; their list enumerates more than four hundred species—a large number being desmids and diatoms—of which several are new species or varieties.

THE order Bombacaceæ, united by Hooker with Malvaceæ, includes, besides the baobab, several remarkable trees, of which the "silk-cotton" trees are a prominent feature in the tropics. Two genera pass by this name, Bombax and Ceiba, or, as it is known in this country, Eriodendron. At Nassau, in the Bahamas, there is a historic giant silk-cotton tree that is assigned to *Eriodendron anfractuosum* in an enumeration of the plants of the Bahamas. The illustration here reproduced is taken from *Forest and Stream*, January 13, and shows the remarkable formation of plank-like outgrowths, produced from the base of the trunk and the uppermost roots, that have received the name of plank-buttresses. The plank-buttress is a peculiarity of trees growing in a tropical climate with abundant rainfall.

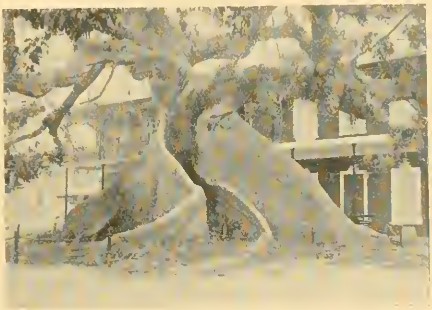

FIG. 1.—The Giant Ceiba Tree of Nassau—one of the famous trees of the World.

MR. AUDOIN contributes an interesting paper on the hydrography of Lake Tchad to *La Géographie* (vol. xii., No. 5). Recent observations of the volume of tributary streams and the area of the lake are analysed and applied to the examination of the question of the gradual desiccation of the region.

MR. MARQUARDSEN contributes a valuable and complete summary of the history of geographical exploration in the Lake Tchad region down to the year 1905 to the new number of the *Mitteilungen aus den deutschen*

Schutzgebieten (vol. xviii., part iv.). With this number is issued a new map of the region, and also a map of Togoland on a scale of 1 : 200,000.

PROF. H. FISCHER and Prof. F. Guillotel write in the *Zeitschrift* of the Berlin Gesellschaft für Erdkunde (No. 10, 1905) and in *La Géographie* (vol. xii., No. 4) on the position of geography, and the teaching of geography, in the United States. In both papers there is much to interest and stimulate teachers of the subject in this country. We note with pleasure the well deserved tribute which both writers pay to the work of Prof. W. M. Davis.

WE have received the annual number for 1905 of *Mazama*, the publication of the well known American mountaineering club. Mr. Henry Gannett contributes a paper on Lake Chelan and its glacier, and Mr. H. F. Reid describes the glaciers of Mount Hood and Mount Adams. The rest of the number is chiefly devoted to accounts of the work of the club during the year. Some of the photographs illustrating the "Rainier outing" are of great excellence.

THE director of the new Japanese Meteorological Service of Corea, Mr. Y. Wada, has lost no time in searching for and publishing the results of observations existing in that country. The Journal of the Meteorological Society of Japan for November last contains summaries of rainfall observations for the years 1896–1904 discovered at Seoul, and compiled in the Chinese language by a Mr. Li. The mean annual rainfall is about 35·4 inches, of which nearly 25 inches fall in the three summer months; July has an average fall of 11·3 inches, and December only 2·8 inches. The greatest daily falls occur in June and July, and exceed 5 inches on rare occasions. Rain falls, on an average, on 94 days in the year, and snow on 19 days.

MR. J. R. SUTTON has communicated to the *Transactions of the South African Philosophical Society* (vol. xvi., part ii.) a useful paper entitled "Some Results of Observations made with a Black Bulb Thermometer *in vacuo*." Mr. Sutton states that the object of the investigation was chiefly to ascertain some of the effects of various meteorological influences upon the indications of the instrument, not to discuss its suitability for the purposes of physical research. We are glad to see, however, that he does not share the opinion that has been sometimes expressed by high authorities of the untrustworthiness of the black bulb thermometer. We think it has been recently shown that good instruments, after use for some years, give fairly accurate comparative results, and, this being the case, their indications afford useful observations which cannot otherwise be obtained at ordinary meteorological stations. The author's observations show *inter alia* that at Kimberley the differences between the maxima in sun and shade increase with fair uniformity from winter to summer, the temperature in the sun increasing faster than that in the shade. A monthly comparison of various elements for four years shows that there is not any very obvious relation between the solar temperature and either the state of the sky or the hygrometric condition of the air, except, roughly, that the amount of cloud is least and the temperature of the dew-point lowest in winter, when the black bulb temperatures are lowest and the difference of maxima least. The elements arranged in a sequence of cloud percentages show that the temperature in the sun is at its highest when the sky is half clouded. Mr. Sutton thinks this seems to indicate that when the sky is more than half covered the clouds are as likely to shut off the solar heat as to impede radiation from the thermometer. We are unable in this brief notice to refer to various other points of interest in the paper.

THE paper on worm contact read by Mr. Robert A. Bruce before the Institution of Mechanical Engineers on January 19 throws much light on the actions involved with worm gearing. Many writers have contributed to the theory of the subject, but hitherto experimental investigation has been singularly incomplete. Some of the most interesting aspects of the question are dealt with by the author, but further research work is necessary before a complete account of the action of worm-gearing can be drawn up. The author's paper will prove a valuable guide to students of applied mechanics, and forms a welcome addition to the proceedings of the Institution of Mechanical Engineers.

THE presidential address of Prof. J. F. Kemp to the New York Academy of Sciences is printed in full in *Science* of January 5. It deals in a popular manner with the genesis of mineral veins. Ores, he shows, gather along subterranean waterways. They may fill clean-cut fissures; they may impregnate porous rocks on either side; or they may replace entirely soluble rocks. As to the source of the water that accomplishes these results there has been much discussion, the crucial point relating to the relative importance of the two kinds of ground-waters, those from the molten igneous rocks and those derived from the rains. The author inclines to regard the latter, if not as the sole vehicle of introduction, as the preponderating one.

IN the current issue of the *Engineering Magazine* (January) there is an interesting account of the first attempt of the United States Government to develop a source of fuel supply in the Philippines, where the economic conditions are favourable, inasmuch as nothing in the shape of a competing private coal-mining industry is established there. Owing to the high calorific power of the coal available, and to the fact that there is an ideal harbour adapted for a coaling station, the small island of Batan was selected as the site for the Government coal mines. The coal is of Eocene age, and the greatest normal thickness of any seam on the island is 8 feet. The coal yields 40 per cent. of volatile constituents and 4 per cent. to 7 per cent. of ash, whilst the fixed carbon in several cases exceeds 50 per cent. The author of the paper, Mr. O. H. Reinholt, was in charge of the development, and the numerous illustrations he gives are reproduced from photographs taken by himself.

MR. CONSUL STEVENS, in his report on agriculture in the Trans-Caucasus for the year 1905, refers, writes a contributor to the *Journal of the Society of Arts*, to the ravages of locusts. The fields situated along the stretch of land north and south of the river Kura are often visited by this insect at a season of the year when, in view of the forward state of the crops, their presence proves most disastrous to the population. The Government has for some years been paying much attention to the destruction of locusts, and with this object in view has endeavoured to encourage the peasants to destroy locusts' eggs, or the larvæ. Accordingly the peasants dig holes or trenches, and during the months of June and July the villagers go out into the fields and drive the larvæ into the trenches. This measure has been crowned with a certain amount of success during the present season, and the havoc done to the crops by locusts has thereby been reduced to a minimum. No fewer than 13,905,276 days' *corvée* work was done between the years 1898 and 1904 in destroying locusts in the Sir.

Darya, Samarkand, Ferghana, Semirechi, and Trans-Caspian districts. This in itself shows the immense sacrifices the natives are called upon by the authorities to make in connection with the destruction of locust eggs. Between the years 1900 and 1905 the rural authorities of those localities paid away sums to the amount of 80,000*l.* for the destruction of locusts, and yet during this period the crops in Central Asia were damaged to the extent of 150,000*l.* by this insect.

THE publication in NATURE of December 7, 1905 (p. 132), of some verses on the passing of the atom, sung at the chemical laboratory dinner at University College, London, has induced Mr. F. Horton, St. John's College, Cambridge, to send us a copy of the post-prandial proceedings of the Cavendish Society, containing several metrical compositions inspired by recent work on ions and radio-activity. Songs of this kind are sung at the Cavendish research students' annual dinner, which is held at the end of each Michaelmas term; and the one by Mr. A. A. Robb reprinted elsewhere in this issue is a good example of versification in science.

IN two recent papers, the one by Mr. D. Himstedt and Mr. G. Meyer, published in the *Berichte* of the Freiburg Scientific Society (1905, vol. xvi., p. 13), and reprinted in *Le Radium* (vol. ii., No. 12), the other by Prof. B. Walter and Mr. R. Pohl (*Annalen der Physik*, iv., 18, 406), experimental evidence is brought forward to show that the light ordinarily emitted by radium bromide is principally due to the impact of the Becquerel rays on the particles of nitrogen in the immediate vicinity. The probability of this being the case was suggested by Sir William and Lady Huggins in 1903, although the latter were unable then to obtain direct evidence in support of their view.

AN important paper by Prof. A. W. Witkowski on the thermal dilatation of compressed hydrogen is published in the *Bulletin International* of the Cracow Academy of Sciences (1905, No. 6). Full details are given of the methods employed in determining the values, already published in a brief report to the British Association in 1904, of the volume coefficient of dilatation of hydrogen at temperatures ranging from $+100°$ to $-190°$ C. under pressures of 1–6n atmospheres. The results are used in discussing Wroblewski's calculation of the critical temperature and pressure of hydrogen, a subject which is also dealt with experimentally by Prof. Olszewski in the following number of the Bulletin (1905, No. 7). The critical pressure was found in a new determination to be 13·4–15 atmospheres, the critical temperature being $-240°·8$ C. Prof. Olszewski also describes in No. 7 an unsuccessful attempt to liquefy helium by allowing it to expand suddenly, after cooling to $-259°$ C. by means of solid hydrogen, from a pressure of 180 atmospheres. Not a trace of liquefaction could be observed at the temperature obtained in this way, which is calculated to be as low as $-271°·3$ C., or $1°·7$ absolute.

AT the last meeting of the physical-mathematical section of the Berlin Academy of Science, held under the presidency of Prof. Waldeyer, Prof. Landolt epitomised the results of his extensive experiments on the question of the possible change of weight caused by chemical action, and stated that he had obtained confirmation of many previous observations of a decrease in weight as a result of certain reactions, and that he had started further experiments with the view of discovering the cause of such changes. Prof. van 't Hoff gave a further contribution to his series of papers on natural salt formations, xlv., the occurrence of tincal and octahedral borax. In collaboration with Blasdale he had observed that the appearance of octahedral borax in Italy was dependent upon a minimum temperature of about $35°·5$ C. Prof. Waldeyer read a communication from Dr. A. Sachs, of Breslau, on kleinite, a hexagonal mercury oxychloride from Terlingua, in Texas. This mineral, to which the formula $Hg_4Cl_2O_3$ is given, is a third addition to the other two mercury oxychlorides previously found in this district, namely, eglestonite, $Hg_6Cl_3O_2$, belonging to the regular system, and the monoclinic terlinguaite, Hg_2ClO.

THE real existence of the *n*-rays, discovered by M. Blondlot, has been the subject of much discussion, there being a general consensus of opinion outside France that the effects produced are physiological. The *Comptes rendus* for January 15 contain two papers of considerable interest on this subject. The first of these, by M. Mascart, gives details of a series of measurements of the points of maximum intensity in the spectrum produced by the refraction of the *n*-rays through an aluminium prism, by a number of independent observers. The phosphorescent screen was mounted on the carriage of a dividing engine, and each of four observers (Messrs. Blondlot, Gutton, Virtz, and Mascart) made independent measurements of the points of maximum intensity. The most concordant figures were those obtained by M. Blondlot, but the general agreement of the results left no doubt as to the position of the lines. M. Mascart gives the results without comment. The second paper, by M. Gutton, is an attempt to prove the objective existence of the *n*-rays. It had been noted that if these rays are allowed to fall on the primary spark of a Hertzian oscillator, the lustre of the secondary spark diminishes. This effect has been secured photographically, the difference being clearly marked in the whole of the thirty-seven experiments. The apparatus is described in detail, and the precautions necessary for success pointed out. These two papers certainly provide material for consideration by those who maintain that the whole phenomenon is a physiological illusion.

PROF. HENRI MOISSAN has continued his experiments on the fusion and volatilisation of the more refractory metals in the electric furnace, and gives an account of his results in the current number of the *Comptes rendus* (January 22). In the first experiment, made with osmium, the temperature obtained by using a current of 500 amperes at 110 volts, although sufficient to distil 16 per cent. of the metal in four minutes, was not sufficient to melt the metal, except at the edges. Osmium was entirely fused with a current of 700 amperes at 110 volts in five minutes, but the fused metal contained nearly 4 per cent. of graphite. Under the same conditions of current and voltage as in the second experiment above mentioned, 150 grams of ruthenium were completely melted in three minutes, about 11 per cent. being distilled during the fusion. The fused ingot of ruthenium also contained graphite. Platinum could be distilled in the same furnace with great ease, and, indeed, Prof. Moissan remarks:—"The liquid metal distils with the same facility as water carried to 100° C." Palladium, iridium, and rhodium were also fused and distilled without difficulty, palladium being the easiest metal to fuse of all those examined in this group.

A SUMMARY of the weather for 1905 at Sevenoaks has been received from Mr. W. W. Wagstaffe.

MR. H. K. LEWIS's quarterly list of new books and new editions added to his Medical and Scientific Library (136 Gower Street, W.C.) during the last three months of 1905

includes more than 150 titles of books, above 30 of which are in the chemical, engineering, and electrical departments of the library.

THE "Writers' and Artists' Year-book" for 1906 has now been published by Messrs. A. and C. Black. It contains much information likely to be of assistance to writers on all subjects. The list of papers and magazines, good though it is, is by no means complete; for though details concerning *Science Siftings* are supplied, we have been unable to find any mention of the *Chemical News*, the *Entomologist*, the *Irish Naturalist*, and the *Zoologist*. The price of the year-book is 1s. net.

MESSRS. ARCHIBALD CONSTABLE AND CO., LTD., have ready for publication immediately the following books of scientific interest:—"Motor Vehicles and Motors," vol. ii., by W. Worby Beaumont; "Tunnel Shields and the Use of Compressed Air in Subaqueous Works," by W. C. Copperthwaite; "Modern Turbine Practice and Water Power Plant," by J. W. Thurso; "The Seven Follies of Science," by J. Phin; "Experimental Electrochemistry," by N. Monroe Hopkins; "Gas, Gasolene, and Oil Engines" (new edition), by G. D. Hiscox; and "Practical Electro-chemistry" (second edition), by B. Blount.

THE twenty-sixth issue of the "Englishwoman's Yearbook and Directory," that for 1906, has been published by Messrs. A. and C. Black. It maintains the high level of usefulness to which attention has on previous occasions been directed in these columns. Englishwomen anxious to take part in the useful work of the world owe a debt of gratitude to Miss Emily Janes, who edits the volume. Great prominence is, as usual, given to education, and the information given concerning the higher education of women is exhaustive and interesting. An alphabetical list of some distinguished women with their contributions to science and education should serve to encourage others to assist in the spread of knowledge.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN FEBRUARY:—

Feb. 2. 5h. Jupiter in conjunction with the Moon. Jupiter 4° 39′ N.
,, 3. 5h. 23m. to 6h. 28m. Moon occults α Tauri (mag. 1·1).
,, 4. 10h. 6m. to 12h. 6m. Transit of Jupiter's Sat. III. (Ganymede).
,, 5. Juno (mag. 8·7) in opposition to the Sun.
,, 7. 7h. 7m. to 8h. 4m. Moon occults ζ Cancri (mag. 4·7).
,, 7. 9h. 33m. Minimum of Algol (β Persei).
,, 8. Total eclipse of the Moon.
17h. 57m. First contact with the shadow.
18h. 58m. Beginning of total phase.
19h. 47m. Middle of the eclipse.
20h. 36m. End of total phase.
21h. 37m. Last contact with the shadow.
19h. 30m. Moon sets at Greenwich.
Magnitude of the eclipse = 1·632.
,, 10. 6h. 22m. Minimum of Algol (β Persei).
,, 10. 11h. 7m. to 12h. 12m. Moon occults χ Leonis (mag. 4·7).
,, 14. Venus. Illuminated portion of disc = 1·000. Of Mars = 0·944.
,, 16. Juno ½° S. of ζ Hydræ (mag. 3·3).
,, 22. 19h. 43m. Partial eclipse of the Sun, invisible at Greenwich.
,, 24. 11h. Saturn in conjunction with the Sun.
,, 28. 7h. 0m. to 8h. 9m. Moon occults μ Ceti (mag. 4·4).

DISCOVERY OF A NEW COMET. A telegram from the Kiel Centralstelle announces the discovery of a new comet by M. Brooks at Geneva on January 26. Its position at 10h. (Geneva M.T.) on that date was

$$R.A. = 16h.\ 19m.\ 28s.,\ dec. = +47°\ 10',$$

which is near to τ Herculis.

The object is said to be a bright one, and to be moving in a north-westerly direction. Being the first comet to be discovered during the year, it will take the designation 1906*a*. At 9 p.m. τ Herculis is fairly low down, near to the N.N.E. horizon, and does not "south" until about 7.30 a.m.

A second telegram from Kiel states that the comet was observed by Dr. Palisa at Vienna on January 28. Its position at 15h. 13·3m. (Vienna M.T.) was

$$R.A. = 16h.\ 18m.\ 16{\cdot}4s.,\ dec. = +50°\ 4'\ 45''.$$

From this it appears that the comet is at present travelling nearly due north towards the constellations Draco and Ursa Minor.

COMET 1905*c* (GIACOBINI). As comet 1905*c* is now emerging from the immediate neighbourhood of the sun and is fairly bright, it should soon become visible in the evening sky, immediately after sunset, and in the south-west. The following is an extract from a daily ephemeris published by Herr A. Wedemeyer in No. 4067 of the *Astronomische Nachrichten*:—

Ephemeris 12h. M.T. Berlin.

1906	α (true) h. m. s.	δ (true) ° ′	log r	log Δ
Feb 1	22 18 6	−25 9	9·6110	0·0616
3	22 40 39	−24 17	9·6634	0·0616
5	23 1 53	−23 9	9·7099	0·0633
7	23 21 49	−21 50	—	—
9	23 40 24	20 25	—	—

OBSERVATIONS OF STANDARD VELOCITY STARS.—In accordance with the international cooperative scheme for the regular determination of the radial velocities of ten standard stars, Mr. Slipher, using the Lowell spectrograph, observed the following stars during the summer and autumn of 1905. γ Cephei was substituted for α Crateris—the tenth star of the standard list—because the latter was too near the sun during the period covered by the observations. The mean velocity obtained by Mr. Slipher for each star is also given below:—

Star	No. of plates	Velocity
α Arietis	3	−14·3 km.
α Persei	5	− 2·5 ,,
β Leporis	3	−13·0 ,,
β Geminorum	3	+ 3·3 ,,
α Boötis	5	− 4·7 ,,
β Ophiuchi	3	−11·3 ,,
γ Aquilæ	3	− 2·1 ,,
ε Pegasi	4	+ 6·1 ,,
γ Piscium	3	−11·3 ,,
γ Cephei	3	−41·9 ,,

Mr. Slipher describes the equipment and the method of working, and directs attention to the fact that the high altitude of the Lowell Observatory and the prevalent transparency of the sky contribute greatly to the light-power of the equipment. Satisfactory spectrograms of α Persei were obtained in 15 minutes, whereas with the Yerkes equipment the shortest exposure on this star was 30 minutes (*Astrophysical Journal*, No. 5, vol. xxii.).

A FIRE NEAR THE MOUNT WILSON OBSERVATORY.—From No. 1, vol. xiv., of *Popular Astronomy*, we learn that a serious fire took place on Mount Lowe, near to Mount Wilson, on December 9, 1905. Fortunately, no damage appears to have been done to the observatory equipment, but the heat was so intense that Prof. Hale, fearing that some of the more delicate parts of the apparatus might be injured thereby, had them removed and sunk in the observatory reservoir until the danger was past.

MEMOIRS OF THE ROYAL SOCIETY OF NAPLES.[1]

THE greater number of the papers published in the last volume of the *Atti* of the Royal Society of Naples deal with geological and palæontological subjects connected with southern Italy. Dr. Maria Pasquale has prepared a catalogue of the fossil remains of Selachians, preserved with the University collections in Naples, and in various other museums in Italy. The majority of the species were already known through the writings of Prof. O. G. Costa,

FIG. 1.—*Hippocampus antiquorum.* From the Pleistocene Clay of Taranto.

who had originally formed the Neapolitan collection, and of Prof. Bassani, in whose custody the specimens now are. With the exception of one possibly Cretaceous species, all are Cainozoic, and no less than twenty-two species come from the *pietra leccese* (Middle Miocene).

The fish fauna of the Pleistocene Clays of Taranto is described by Prof. F. Bassani (No. 3, 59 pp., 3 pls.), principally from a collection of 700 specimens obtained by Dr. Marchesetti during the excavation of a new dry dock at Taranto in 1886. From beds of clay varying from 10 metres to 73 metres in thickness come 9 species of algæ, including the new *Grateloupia bassanii*, which form the subject of a special memoir by Dr. A. de Gasparis (No. 4, 8 pp., 1 pl.), and 29 species of fish, all of which are found living in the Mediterranean at the present day, and many of which may be seen on the stalls of the fish market in Taranto. Certain genera, Hippocampus, Scopelus, Maurolicus, Heliastes, Mullus, and Trachypterus, do not appear to have been recorded in the fossil state before these Tarantine discoveries. The occurrence of many individuals belonging to near-shore-living genera, like Solea, suggests that the fauna was essentially a littoral one, and the presence of such deep-sea types as Nyctophus (=Scopelus) or Maurolicus is hardly to be regarded in any other light than the occasional upheaval of the *dead* bodies of abyssal forms in the Straits of Messina at the present day. Bones of a dolphin are recorded from the same deposits.

[1] "Atti della Reale Accademia delle scienze fisiche e matematiche di Napoli." Vol. xii. (1905.)

Dr. M. Pasquale also contributes a short illustrated description of another fish, *Palaeorhynchus deshayesi*, Agassiz, from the Eocene deposits near Barberino di Mugello, Florence (No. 8, 7 pp., 1 pl.).

Two important contributions to the palæontology of the Gulf of Naples deal with the corals of Capri and with the Triassic shells of Giffoni, near Salerno. Prof. de Angelis d'Ossat has proved that the Capri limestones of Venassino, which have hitherto been generally believed to be of Tithonic age, in accordance with the view of Oppenheim (1889), are far more nearly related in their coral-fauna to the Urgonian rocks. Out of a total of 25 species of corals, 18 are shared with the Urgonian, only 1 with Tithonic deposits. Several species of Amphiastræid and Astræid corals are described and figured as new to science, and an Acanthocœnia is named after Dr. Cerio, the discoverer of this rich deposit, who has devoted so much of his life to the study of the natural history of Capri. The dolomitic limestone of Giffoni has already been made known by the work of Costa and Bassani on the fish-fauna. In Dr. Galdieri's memoir (No. 16, 30 pp., 1 pl., 21 figs.), which is in the main a revision of O. G. Costa's work of forty years ago, an attempt has been made to determine the exact chronological position of the Giffoni beds with respect to others both in Italy and the Alps. More material will be required before certain conclusions can be drawn, but at the present state of knowledge there is fair evidence of contemporaneity with the well known Triassic strata at St. Cassian.

An interesting note bearing on the same general subject of the limestones of the Bay of Naples is on the Scoglio di Revigliano, by Prof. de Lorenzo (No. 12, 4 pp., 2 pls.). Revigliano Island is a tiny islet rock of Cretaceous, perhaps of Urgonian, age, which, were the sea to be removed, would be seen to rise by itself from a gently sloping plain of volcanic deposits, among which pumice, like that which buried Pompeii in the year 79, would be conspicuous, as well as the products of other Vesuvian and Campanian eruptions. The strata of the little rock dip in the same direction as those of the Sorrentine peninsula, viz. to the north-west, and they indicate by their trend the existence of a great fault, all other trace of which is buried beneath the alluvial and volcanic deposits of the Sarno-Castellamare plain.

The granitoid and Filonian Rocks of Sardinia form the subject of a posthumous memoir of Carlo Riva (No. 9, 108 pp., 7 pls.), which has been prepared for the press by his friend and colleague Prof. de Lorenzo. After describing the petrographical characteristics of the chief varieties of rock in detail, the author gives a valuable account of seventeen localities in Sardinia where zones of contact between the granites and schists and calcareous rocks may be well studied, together with an appreciation of the metamorphic changes that have taken place at each locality. The memoir concludes with a discussion of the theories of the probable age of the granitoid rocks of Sardinia.

FIG. 2.—Revigliano from the south-east.

Dr. V. Bianchi has re-investigated certain parts of the brain of *Delphinus delphis* (No. 14, 16 pp., 3 pls.), and has compiled an interesting table setting forth his estimates of the relative numbers of neuroglœal corpuscles and of nerve cells in various regions of the cerebral cortex.

Although the cerebral hemispheres resemble those of the carnivorous type, yet the frontal lobes are so singularly under-developed that the author finds therein an explanation of the relative stupidity of the dolphin.

"Bidder's Organ" (Spengel) was discovered in 1758 by Rösel von Rosenhof upon the testes of *Bufo calamita*. Dr. Attilio Cerruti, by means of material captured in the volcanic crater of Archiagnano, near Naples, has been able to demonstrate a highly interesting cytological process which occurs in the male individuals of *Bufo vulgaris* during the early months of the year. Certain of the cells, named ovules, of the organ of Bidder are so strongly attracted by some of their neighbours that they actually penetrate their enveloping membranes, and their cytoplasm and nuclei flow into the invaded cells. In the majority of cases the penetration is simple, *i.e.* only one ovule invades a second, but multiple penetration has also been observed; and then in the case of ovules, say, *a*, *b*, *c*, *d*, ovule *a* will penetrate into *b*, *b* into *c*, *c* into *d*, &c. In all cases of penetration, degeneration ensues. Generally speaking, the invading ovule is the younger, and is one which has developed on the periphery of the organ, the invaded ovules lying nearer the centre. The author draws a suggestive comparison between this phenomenon and that of the fusion of Ascaris ova described by O. zur Strassen, which, if they develop at all, give rise to monsters.

There are also four mathematical memoirs. Signor D. de Francesco contributes a paper on the motion of a cord and on the equilibrium of a flexible but non-extensible surface (Nos. 5 and 6, 5 pp., 9 pp.), and Prof. E. Cesàro investigates the intrinsic representation of a surface (No. 7, 20 pp.) and the curve of von Koch (No. 15, 12 pp.). A lengthy contribution to the theory of ternary biquadratic form and its resolution into factors (No. 13, 102 pp.) is by the hand of Ernesto Pascal.

R. T. G.

PHYSIOLOGICAL ECONOMY IN NUTRITION.

ONE of the most remarkable points in the recent history of physiological research is the small amount of attention bestowed upon the important question of nitrogenous metabolism until within the last few years. The older work of Voit and of Pflüger has for long been regarded as authoritative, in spite of the fact that these two observers are not at one on many essential facts. They, however, agree that proteid food is a most essential constituent of our diet, and that a minimum allowance per diem of about 100 grams, corresponding to 16 to 18 grams of nitrogen, is necessary for the well-being and equilibrium of the average adult human individual. A dietary containing this amount of proteid or albuminous material would not be regarded by the average meat-eating Englishman to be a very liberal one, and is frequently exceeded.

So firmly rooted has this idea of a proteid minimum intake of 100 grams become that not only is it stated as an axiom in the majority of text-books, but it forms the basis of dietaries prescribed by responsible Governments for use on military service, &c. The doctrine that proteid food is the most necessary of all foods is so thoroughly ingrained, even upon the lay public, that in popular parlance the words nutritious and nitrogenous are almost synonymous. This is a very dangerous mistake, for the non-nitrogenous constituents of diet, the carbohydrates and the fats, are equally necessary for the maintenance of bodily heat and energy, and so are equally, though in a somewhat different sense, to be regarded as nutritious. An example of this erroneous way of regarding food is to be seen in advertisements that meet the eye everywhere; preparations of milk, for instance, are sold which contain mainly the proteid matter of that fluid, and are vaunted as containing all the nutritious elements, the other constituents being looked upon as useless. As a matter of fact, milk is of special value on account of the admixture of the non-proteid with proteid material. In the concentration camps which were established during the later phases of the South African War, such hardships as occurred there were mainly due, not to lack of proteid nutriment, for the standard of nitrogen was fully maintained, but to lack or scarcity of vegetables and other sources of carbohydrate food.

For some considerable time, certain experimenters in Germany have striven to demolish the fetish of the irreducible minimum of the 16 or 18 daily grams of nitrogen, but their work has not attracted world-wide acknowledgment; the experiments they recorded were either made for too short a time or on too few people to be regarded as epoch-making.

It has been left to America to make the question one of immediate and urgent attention, and I propose in this article to bring the conclusions of these American investigators before the readers of NATURE.

Prof. R. H. Chittenden, of Yale University, and Dr. Otto Folin, of Waverley, Massachusetts, are the two principal exponents of the new doctrine, and I propose to deal with them in that order.

The Work of Chittenden.

Chittenden has been working at the subject for some years, and the results of his labours are given in a volume which will amply repay perusal entitled "Physiological Economy in Nutrition" (New York: F. A. Stokes Co., 1904). A more popular exposition of his ideas has been published in a recent number of the *Century Illustrated Monthly Magazine* (October, 1905, p. 859 *et seq.*).

The question was first brought to the notice of Prof. Chittenden by Mr. Horace Fletcher, who states that he cured himself of dyspeptic troubles by lessening his proteid nutriment below what was regarded as the physiological standard. He has started a propaganda on the subject from the economic point of view, for proteid is the most expensive of the articles of diet. One at once sees that the question is not merely one for the student of science, but is most important for the man in the street as well. Owing, no doubt, to his lack of physiological knowledge, Mr. Fletcher attributed the benefits he derived to a thorough mastication of the comparatively small amount of food he took. Mastication is, of course, of importance, but it does not possess the superlative importance attributed to it by Mr. Fletcher, and will not explain the results of the experiments made by Chittenden and his fellow-workers.

The number to which I have already alluded (16 to 18 grams of nitrogen a day) is based roughly on the usual diet of the meat-eating nations, and it is argued that habit and instinct alike are safe guides in determining such a number, and the effects of such a diet in the maintenance of health and bodily equilibrium have been abundantly proved through centuries of experience. It forms, as already stated, the basis of the usually accepted dietaries of Ranke and of Voit.

In other nationalities, it is true, a different figure has been arrived at, and the same argument of habit and experience might equally well be used in its favour. Thus in certain semi-civilised races the proportion of flesh food is much larger, and in other races, again—and this is the commoner variation—the proteid intake is less. We need, however, only consider the second alternative, for one can hardly suppose anyone will advocate a return to more carnivorous habits. It is alleged that in such nationalities as the Japanese, or in groups of people like vegetarians, and in certain rural populations, health and equilibrium are as well maintained as in the ordinary meat-eating inhabitants of our large cities. Those who hold that the number 16 to 18 is the correct one have explained the different number arrived at by the nations of the Far East as a racial difference propagated by long centuries of inheritance, or have tried, more or less successfully, to show that such people come nearer to Voit's standard than had been supposed, or else that they are not properly nourished.

Such explanations will not hold water when applied to the experiments conducted by Prof. Chittenden upon himself, his colleagues, his students, and upon a considerable number of athletes and soldiers. These experiments lasted in all cases for months, and in some for more than a year. The proteid intake was reduced to half, and in some cases to less than half the number hitherto regarded as normal. After a variable initial drop in body-weight, the deprivation was apparently followed by no untoward results. Equilibrium was maintained; the health remained

perfect or improved; the muscular power of athletes was increased; mental acuity was undiminished; and desire of richer food disappeared.

Chittenden argues from such results (and daily observations were diligently maintained throughout each experiment) that his scanty proteid diet is the normal, and that the average meat-eater is the man who is abnormal. He says:—"When we recollect that these eighteen grams or more of nitrogen in the urine reach the final stage of urea, &c., only by passing through a series of stages each one of which means the using up of a certain amount of energy to say nothing of the energy made use of in digestion, absorption, &c., we can easily picture to ourselves the amount of physiological labour which the daily handling by the body of such amounts of proteid food entails. It needs very little imagination to see that a large amount of energy is used up in passing on these nitrogenous waste products from organ to organ or from tissue to tissue, on the way to elimination, and we can fancy that liver and kidneys must at times rebel at the excessive labour they are called upon to perform." He then goes on to point out that many of these waste products, like uric acid, are toxic, and the evil results that ensue from their accumulation.

It is on such grounds that Chittenden advocates a revolution in our ordinary dietary, and his arguments for temperance in proteid intake are entitled to careful attention. He is no crank or faddist, and his conclusions have been arrived at by the true scientific method, that of experiment.

There will be many who will pay no attention to them at all. The *bon vivant*, for instance, will resent any interference with his habits, gout and other evils notwithstanding; and certainly some of the meals Chittenden describes do not appear very appetising; for instance, a banana and a cup of coffee for breakfast; bean soup, bread (1 oz.), bacon ($\frac{1}{6}$ oz.), fried potato, salad, prunes, and another banana for supper. But no doubt variations in the way in which the nutriment can be obtained are possible of introduction.

The honest inquirer after truth may also have his doubts, and it cannot be disputed that there are difficulties, and serious ones, which will have to be answered before the advocacy of the new idea will meet with success.

One would like to know, for instance, whether the numerous subjects of the experiments are still keeping up their reduced diet, or whether they have returned to the flesh-pots after a period of enforced abstinence. If they are still maintaining their new habits, one would like to know how they fare in a few years' time, if they have the reserve force to enable them to withstand a severe disease, great fatigue, or privation during a siege, and whether the initial briskness they felt when they dropped their large (probably too large) proteid intake is maintained, or whether, on the other hand, they present the appearance and symptoms of underfed persons.

A cautious and conservative person would point to the danger of a sudden change in the habits of years and generations, even though it may ultimately be necessary. Most physiologists will recall the analogy of metabolic changes to commercial undertakings which they employ when presenting balance-sheets of intake and output in the body, and say, just as in a business enterprise, a large turnover implies healthy activity, so in the body a frequent exchange of the old for the new is within certain limits an indication of vigour, and a necessary accompaniment of healthy action. The liver, the function of which it is to turn nitrogenous metabolites, which may be harmful, into urea, which is harmless and easily disposed of, is adequately large and active in health to deal with considerable quantities of material.

Then we may point to the stunted and feeble inhabitants among the poor and ask why they are so. Unhealthy dwellings, excess of alcohol, insufficiency of light and pure air will explain a good deal of their condition; but is it not underfeeding, especially in early life, which is at the root of the matter? They have had *nolens volens* to subsist on a diet very like Chittenden's, but their nutritive condition is not such as to make people who can afford a more liberal table inclined to follow their example.

Further, one may inquire, why is it that, with a few exceptions, the meat-eating nations have risen to the front? and why is it that in countries like India, where the native population is diluted with the white races, it is the former who are more readily attacked by disease, and more easily succumb to its effects?

A question intimately related to that of a suitable diet for the healthy adult is that of the feeding of children. The diet of the growing infant is relatively far richer in proteid than that of the adult. Must we also reduce the intake of proteid food in the child? This is a question that Chittenden has not touched, but clinical experience does not point, so far as I can ascertain, to an affirmative answer, either with regard to the feeding of infants or of certain classes of invalids.

These questions and difficulties cannot be answered offhand. There is a wide field still open to investigators, and not until such difficulties are removed will it be possible for physiologists to state that Prof. Chittenden has convinced them.

The Work of Folin.

Whether Dr. Otto Folin has seen these difficulties or not, he certainly does not mention them, and he appears as an advocate of the new doctrine, not only from a study of Chittenden's investigations, but also as a result of his own researches. Nitrogen enters the body in the complex compounds known as proteids; it leaves the body mainly by the urine in the shape of certain simpler substances of which urea is the most abundant. Folin has approached the subject from the aspect of nitrogenous discharge, and has published his investigations on the urine in a series of three interesting papers in the *American Journal of Physiology* (vol. xiii., 1905, pp. 45–65, 66–115, 117–138). Although it is possible that some of his conclusions may not stand the test of time, all of them are most suggestive, and his theory of proteid-metabolism will stand out as one of the most important contributions to physiological literature that has appeared within recent times.

The question, what is a normal diet? is intimately bound up with another, and that is, what is a normal urine? The text-book statements on the composition of this fluid are all derived from the examination of the urine of people accustomed to the Voit dietary; but if the diet of the future is to contain only half as much proteid, the urine of the future will naturally show a nitrogenous output of half that which is now regarded as normal. In people on such reduced diets, Folin shows that the decrease in urinary nitrogen falls mainly on the urea fraction, and in some cases the urea accounted for only 66 per cent. of the total nitrogen eliminated. The other nitrogenous waste products alter but little in absolute amount, but relatively their amount rises; in particular, the creatinine remains remarkably constant in absolute amount in spite of the great reduction in the proteid ingested. He goes on to point out that the laws governing the composition of urine are the effect of more fundamental laws governing proteid katabolism. Voit's well known theory on this question states that katabolism, *i.e.* the breaking down stage, occurs only in "circulating proteid"; the small amount of "living proteid" which dies is dissolved, and is then added to the "circulating proteid," where the final breakdown into waste products takes place. Pflüger, on the other hand, believes that all proteid taken in as food is first assimilated and becomes a corporate part of living cells before it undergoes the katabolic change. This view has met with more general acceptance than Voit's. The opinion held by Folin is that neither of these extreme views is correct, but that nitrogenous katabolism is of two kinds: one is inconstant and immediate, varies with the food, and leads to formation of urea and inorganic sulphates, but not of creatinine and "neutral sulphur." The other is smaller in amount, constant in quantity, and is largely represented by creatinine, "neutral sulphur," and to a less extent by uric acid and ethereal sulphates. This latter form of metabolism, representing the breakdown of actual living substance, may be termed tissue or *endogenous* metabolism, whilst the other is *exogenous*. Exogenous metabolism therefore represents an immediate discharge of the nitrogenous constituent of proteid matter, leaving the non-nitrogenous moiety available for use in heat and energy production, fulfilling, in other words, the same func-

tion as carbohydrate and fat. Endogenous metabolism sets a limit to the lowest level of nitrogenous equilibrium attainable, and the proteid necessary to balance this part of the nitrogenous waste is indispensable for the repair of the tissues. Whether the amount exogenously katabolised can be entirely dispensed with is at present questionable. I fancy most physiologists would agree that it cannot with safety be wholly dispensed with; the body would then be working too dangerously near the margin, and in any case where an excess of nitrogenous waste is necessary the call would have then to be made on the tissue proteids.

Recent researches on digestion of proteids in the alimentary canal have shown that they are largely broken down into simple substances like ammonia, leucine, tyrosine, and other amino-acids. This is regarded by Folin as a preliminary means of getting rid of the excess of proteid matter usually ingested; these waste products, according to this view, are taken to the liver, rapidly transformed into urea, and so got rid of. The evidence that they are synthesised by the cells of the body into "living proteid" is regarded by him as inconclusive and largely teleological. An extensive formation of Voit's "circulating proteid," to be followed immediately by decomposition into urea, is quite as improbable as the corresponding formation and decomposition of Pflüger's organised protoplasm. The organism requires in its food only the small amount of nitrogen necessary for endogenous metabolism; the nitrogen of the extra proteid is unnecessary, and the organism has at hand an active mechanism for casting it out.

To attempt to summarise all the points of detail into which Folin enters is beyond the scope of this article; all I desire to do is to bring forward the main principle of the new idea. There is, however, one further point of sufficient importance to warrant specific mention, and that is the one related to muscular work. The fact that muscular work does not increase proteid katabolism may be accepted as an approximate truth; it is not absolutely true; there is a certain increase of nitrogenous waste, but it is insignificant as compared with the enormous and immediate increase of waste carbonaceous products like carbon dioxide that are discharged when muscles are thrown into action.

If current views on the nature of proteid katabolism are correct, this fact is very difficult to explain, but it becomes intelligible if proteid katabolism, in so far as its nitrogen is concerned, is independent of the oxidations which give rise to heat or to the energy which is converted into work. "Whether severe work will have an effect on the endogenous metabolism cannot be shown by investigating urea excretion; determinations of creatinine and 'neutral sulphur' are necessary for a study of that question" (Folin).

One of the benefits such papers as those of Folin confer is that new ideas of this kind suggest fresh work to others, and it can hardly be doubted that in the future physiological literature will contain many papers criticising and supplementing the theories and facts which Folin has brought forward. Already one of these has appeared in the current issue of the *Journal of Physiology* (Noël Paton, vol. xxxiii., p. 1, 1905). In this Dr. Noël Paton on the whole agrees with Folin concerning the dual nature of proteid metabolism. He, however, differs from him in certain points of detail. He finds in the dog, for instance, that creatinine excretion is not so constant a quantity as in man. He also doubts whether it is possible to draw any hard and fast line between endogenous and exogenous metabolism, and that urea may be a final product of both. He explains some of Folin's results by variations in the activity of the liver, for it is in this organ that ammonia compounds and the like are transformed into urea. A study of various diets upon the flow of bile (which may be taken as an index of hepatic activity) shows that proteid diet specially stimulates the metabolic processes in the liver. Hence on a diet which is poor in proteid the hepatic action may be sluggish, and will therefore fail to convert a large quantity of waste nitrogen into urea, while on a diet rich in proteid the conversion must be much more complete. As with the nitrogen, so with the sulphur, the amount of which is completely oxidised must be determined by the activity of the changes in the liver.

Such, then, is a brief summary of some of the recent work in connection with these most important problems. We can hardly doubt that the steps made are in the direction of progress of knowledge, but it is as yet too early to prophesy where they will ultimately lead us.

W. D. H.

PHOTOGRAPHY IN NATURAL COLOURS.

An exhibition of photographs in which the aim of the photographer has been to imitate the colours of the objects represented is now open at the offices of the *British Journal of Photography*, 24 Wellington Street, Strand, and will remain open until the beginning of March. The specimens are all direct photographs in the sense that they have been produced by photographic printing, and not in printing presses from blocks or plates. The editors of the *British Journal of Photography* must be congratulated in that they have succeeded in bringing together a more representative collection than has ever been on view before.

The first glance that one instinctively takes round a room immediately on entering it produces a feeling quite different from that experienced on giving a momentary and general look round in a small gallery of paintings. In the latter case there is an impression of completeness in the work that gives satisfaction, whether or not this is maintained when the pictures are more carefully examined; but here there is a sense of a want of finish, an impression of experiment or incompleteness, as if those who made the pictures had left off before they had got the effect they sought to get. Perhaps others will not experience the same feeling, but it was very marked in the case of the writer, and, so far as the origin of it could be traced, it appeared to be due to a general crudeness of colour, or the predominance of one certain colour over the whole picture, or an indecision of outline that was evidently not intentional. Some examples suffer in one way and some in another; a few are quite satisfying, and must be very excellent if not perfect, but they are not in a sufficient proportion to affect the general impression.

It will hardly require technical knowledge to convince the visitor that the personality of the photographer has a great deal to do with the result. The more skilful the worker the better the photograph, that is, the more true are the colours and the fewer the errors of manipulation in all ways. As the skill of the worker has so much to do with the result, it is impossible to decide as to the merits of the various methods. Strictly speaking, it is not possible to determine the value of any of the photographs, for in no case is the original put by the side of it. Who would ever dream of attempting to judge the merits of a copy except by comparing it with the thing copied? Yet the writer has never seen or heard of a demonstration of the possibilities of a method of colour photography by an exhibition of a coloured object and its photograph side by side.

The effect of the personal element, or, in other words, the varying skill (or perhaps the varying luck) of different workers, is very clearly shown in the examples of the same process by different persons, or where an optically inferior method gives a better result. As an example of this last we would refer to Nos. 12 and 33, both apparently from the same group of fruit, &c., and both made of three superimposed films. In No. 33 the films are not cemented together, yet this picture is brighter than the other.

The only example of the immediate production of the colour of the incident light, and in this case the colour is not pigmentary but due to interference and visible only at a certain angle, is a very successful spectrum by the Lippmann process contributed by Mr. E. Senior. With two or three exceptions, the rest of the exhibits are three-colour prints. The fundamental principles are the same in all. Three-colour records are made by photographing the object through coloured media, getting the red, green, and blue of the object separately recorded. From these three negatives suitably coloured prints are made and brought together. In the Joly process, two specimens of which are lent by Mr. E. J. Wall, the three colours are arranged in series of fine parallel lines, and it is necessary to get so far away that these lines are indistinguishable, otherwise they are annoying to the spectator. The starch-grain method of

Messrs. Lumière gets over this difficulty of the lines by coating a plate with a single layer of starch granules which have been previously suitably coloured in three batches and then well mixed. The disposition of the three required colours is thus irregular, and the separate points of colour are too small to be discriminated by the naked eye. Unfortunately, no example of this method is on view; probably the inventors do not care to show their results until they have perfected the process. But this is the only notable process not represented.

In the rest of the exhibits the three coloured prints are superimposed, the variations being in the methods of their production and assembling. In the Sanger-Shepherd process three separate films are prepared, stained, and cemented together. Several exhibitors have adopted this process, chiefly in the production of transparencies, but there are a few prints on paper, and of these a portrait, No. 11, is worthy of special commendation. Dr. B. Jumeaux's modification consists in getting the blue element as a toned bromide print, and then superimposing the red and yellow films. Captain Lascelles Davidson and Mr. O. Pfenninger show specimens in which the films are superimposed but not cemented together, and there are other modifications that are not described.

Instead of three stained films, the prints may be prepared from pigmented tissue by the ordinary carbon process. The Autotype Company, the Rotary Photographic Company, Mr. W. E. Brewerton, M. Leon Vidal, the Lumière N.A. Company, and Dr. A. Hesekiel and Co. exhibit prints by various modifications of this method of working, the last named adopting the Selle process introduced several years ago. Mr. W. E. Brewerton shows how the gum bichromate process may be adapted for the purpose, each of the three coloured elements being produced in turn on the same sheet, with no transferring. The two "winter landscapes" by Dr. H. Bachmann are stated to be three-colour prints in gum bichromate, but the colours are scarcely, if at all, perceptible. The "pinatype" process has recently been described in these columns. In this case three colours are absorbed in turn into a single gelatin film from prepared gelatin films previously soaked in the colour solutions. Messrs. Fuerst Bros. show specimens of it, and Dr. E. F. Grün some results of undescribed modifications.

One of the most interesting exhibits is the group numbered from 52 to 56, examples of coloured prints obtained by a single exposure of a piece of coated paper under the coloured original, the colours being reproduced in the print. The sensitive material has the necessary three colours, each in its own film, superimposed, so that it appears black. By exposure to white light the dyes are all bleached, but if the light is coloured the corresponding colour is not bleached, because the dye does not absorb light of its own colour. This process has been worked at for many years by several investigators, the fundamental difficulties being to find the colours of the right tints that shall be sufficiently sensitive, that is fugitive to light, and can be made sufficiently stable when the print has been produced. These examples are by Szczepanik's method, and show surprisingly bright and clean colours. It is a pity that the original "lithophanes" are not shown as well as the copies, as many will doubtless consider that they are withheld because the comparison would not be to the advantage of the prints. Whether this is so or not, the results are wonderfully good considering the difficulty inherent in such work.

Of the three negatives exhibited by Dr. J. H. Smith and Co., obtained by one exposure in an ordinary camera, the plate used having superimposed on it three sensitive films with the necessary colour screens, there is nothing to be said, as there is no example of the plate used or of the print that the negatives might give. The results on "multico" tissue, which has several layers of pigmented tissue and is used as in carbon printing, the "mars star" prints which are produced by applying colours to bleached bromide prints, and the two portraits by Mr. Burgess can hardly be regarded as serious attempts to reproduce mechanically the colours of the originals until more is known about them. They are better described as colour effects, and there might be some interest attaching to them if the methods of their production were known.

C. J.

THE INTERNATIONAL METEOROLOGICAL CONFERENCE AT INNSBRUCK.

Fourth Meeting, September 14, 1905.[1]

THE president, Prof. J. M. Pernter, announced that after the discussion of a proposition made by Father Froc the meeting would proceed to elect the International Committee. By accepting Father Froc's proposition, the committee recommended the observation of the zodiacal light whenever possible, and assigned a definite symbol for use in reports.

On the proposition of Prof. von Bezold, the following committee was re-elected:—Messrs. Chaves, Davis, Eliot, Hellmann, Hepites, Hildebrandsson, Lancaster, Mascart, Mohn, Moore, Palazzo, Paulsen, Pernter, Russell, Rykatcheff, and Shaw.

Also, on the proposition of Prof. von Bezold, Prof. Nakamura, of Japan, was elected in succession to the late Dr. Billwiller.

Prof. Pernter proposed that the presidents of the commissions should be added to the committee, but it was decided that six months' notice should be given of any propositions which would affect the constitution of the committee.

Prof. Hildebrandsson presented the report of the commission on squalls. It was arranged that the question of the study of squalls should be left in the hands of Messrs. Durand-Greville, Hildebrandsson, and Shaw, and that meteorological institutions, including aëronautical stations, should be asked to send to these gentlemen, upon demand, for a certain number of days, about ten per year, the necessary observations for the construction of accurate charts of isobars, with the diagrams of pressure, temperature, and wind for the purposes of this special study.

Prof. Hellmann reported on behalf of the commission on the international code and on the comparison of barometers. The conference considered the publication of the international code, of the resolutions passed by, and of the papers presented to, the international conferences to be a valuable and powerful means of facilitating and developing international meteorological research, and expressed a hope that the meteorological institutions in Berlin, Paris, and London would undertake the publication in German, French, and English. Thanks were voted to Father Algué, who proposed to publish them in Spanish, and to Profs. Hellman and Hildebrandsson for their preparation of the code.

After some discussion as to the best means of comparing the barometers in different countries, it was decided to put into operation the decision of the conference at Vienna relating to the inspection of the stations in the control of each country. The comparison, wherever possible, was to be extended to extra-European countries. This work was left to Prof. Hellmann and General Rykatcheff.

General Rykatcheff presented propositions from the magnetic commission dealing with the necessity of bringing the magnetic instruments in the various observatories into agreement, and with the desirability of an early exchange of diagrams after days of magnetic storms, or whenever the records may be specially interesting.

Fifth Meeting, September 15, 1905.

The president of the solar commission, Sir Norman Lockyer, presented the report of the meetings of that commission during the preceding days, and also the report of the meeting at Cambridge in 1904. The committee approved of all the resolutions contained in the report, and re-elected the commission, with Sir Norman Lockyer again as president.

The commission expressed the opinion that permanent meteorological observatories should be established in the north of Siberia and America, at least two or three in each country. It also desired to obtain all the observations that may have been made in a large number of islands scattered over the globe, the names of which were given, and insisted on the necessity of continuing these observations, asking that the attention of the Governments concerned should be directed to this matter. Directors of

[1] Reports of the proceedings of the first three meetings appeared in NATURE of September 21 and October 5, 1905 (vol. lxxii., pp. 510 and 562).

meteorological services were asked to furnish data of the heights and flow of rivers and lakes whenever possible.

M. Teisserenc de Bort reported from the commission on the atlas of clouds, and gave particulars of certain alterations in the plates in that atlas and in the definition of stratus cloud.

M. Teisserenc de Bort and Dr. Rotch gave an account of an expedition through the regions of the trade wind and equatorial calms in the North Atlantic. M. de Bort gave the history of the expedition and the results of the observations obtained by means of captive balloons, and Dr. Rotch gave those obtained by kites. Prof. Hergesell followed with the results similarly obtained in the Mediterranean on board the yacht belonging to the Prince of Monaco.

Dr. Köppen announced that the German hydrographical expedition to the Bismarck Archipelago would similarly use balloons and kites during the voyage.

Prof. Mohn reported from the commission on meteorological telegraphy.

M. Polis directed attention to the fact that the *Daily Telegraph* already announces the coming of storms from the Atlantic, using observations sent by means of wireless telegraphy from ships at sea. The conference then passed the following resolution:—"This conference is convinced that wireless telegraphy is chosen to render in the future great service in the forecasting of the weather in the Atlantic, but before introducing it into the current service of the meteorological institutions it is indispensable to take satisfactory precautions for the control of the observations transmitted. The conference asks the Meteorological Office in London to prepare as quickly as possible a report on this question, and communicate with the other meteorological institutions that may be specially interested in the matter."

During this meeting it was announced that M. Mascart had been elected president, and Prof. Hildebrandsson secretary, to the committee, and that the following commissions had been renewed:—Magnetic commission, president, General Rykatcheff (St. Petersburg); aëronautical commission, president, Prof. Hergesell (Strasburg); solar commission, president, Sir Norman Lockyer (London); commission on radiation, president, Prof. Ångström (Upsala). After thanking the reporters of the various commissions for their reports, the president declared the session at Innsbruck to be at an end.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD. The Vice-Chancellor has appointed Lord Curzon of Kedleston to be Romanes lecturer for 1906.

The following elections have been made to the University mathematical scholarships:—to the senior scholarship, A. Holden (Balliol College); to the junior scholarship, A. V. Billen (University College); to the exhibition, J. Hodgkinson (Jesus College).

G. E. Beaumont (Magdalen College School) has been elected to a natural science scholarship at University College.

Scholarship examinations in natural science will take place on March 13 at Keble College, and on April 24 at Merton College, New College, and Corpus Christi College.

CAMBRIDGE.—The board of biology and geology has reported to the Senate on the disposition of its share of the Gordon Wigan fund, which amounts to about 150*l*. The following assignment has been made for 1905 and following years:—(*a*) A grant of 50*l*. a year to Dr. D. Sharp, for a period of five years (1905–9), or such part of it during which he holds the curatorship in zoology; (*b*) a grant of 50*l*. out of the income for 1905 to Prof. Hughes, to enable Mr. E. A. Arber to continue his researches into the stratigraphical and geographical distribution of fossil plants; (*c*) the balance of the fund for 1905, and a grant of 50*l*. for each of the years 1906 and 1907, to Mr. A. C. Seward, to enable the botanic garden syndicate to offer greater facilities for plant-breeding experiments. The same board strongly recommends that the agreement between the University and Dr. Dohrn, director of the zoological station at Naples, be renewed for a further period of five years, by the payment to him of 100*l*. per annum out of the Worts travelling bachelors' fund, such period to date from Michaelmas, 1906.

Mr. D. G. Hogarth will lecture on "Geographical Conditions affecting Population in the East Mediterranean Lands" in the Sedgwick Museum on Tuesday, February 20, for the board of geographical studies, and Dr. Hans Gadow is to lecture to-day before the Antiquarian Society on "Aztec Civilisation and its Origin."

THE council of the University of Liverpool at a meeting held on January 23 passed the following resolution:—"That on the recommendation of the Senate a readership in ethnography be instituted in recognition of the scholarship of H. O. Forbes, LL.D., director of the Public Museums of Liverpool, and that Dr. Forbes be appointed to the said readership."

IT is announced in *Science* that Mr. N. W. Harris, of Chicago, has presented 5000*l*. to North-western University, to be used as an endowment for an annual series of lectures to be delivered by some distinguished man, not a professor of the university, upon the results of his own investigations in scientific, literary, economical, or theological problems. From the same source we learn that by the will of Andrew J. Dotger, of South Orange, N.J., the Tuskegee Normal and Industrial Institute will, at the death of the testator's wife, receive the residuary estate, said to be about 100,000*l*.

IN an address delivered to the Manchester section of the Society of Chemical Industry, Dr. G. H. Bailey, as chairman of the section, dealt with the question of higher education and chemical industry, pleading for more cooperation between manufacturers and teachers. If success is to be achieved in the chemical industries of this country, Dr. Bailey considers that there must be a great change in the curriculum hitherto adopted in our universities and colleges; moreover, "a satisfactory curriculum can only be assured by a more intimate association of the teaching authorities, whoever they may be, and the leaders of industry." In considering the present state of English industry and the methods necessary to ensure its prosperity, Dr. Bailey remarks:—"progress in manufacture must indeed be regarded as a safeguard to stability, far more potent than any political or economic device for the protection of interests, and that nation must succeed in industry, which keeps this clearly in view and possesses the talent wherewith to meet the ever changing demands made upon it."

VISCOUNT HAYASHI, the Japanese Ambassador, distributed the prizes to the successful students of the Northern Polytechnic Institute, Holloway, on January 25. In the course of a subsequent address, he said that scientific research made such strides in the past century that it is no exaggeration to assert that the present is the age of practical application in every phase of modern life. Therefore there is nothing more important in a national system of secular education than institutions which keep abreast with the stride of science. Viscount Hayashi explained then that he took part in the administration of the technical college in Tokio. That college was established some thirty years ago with the help of many British professors and men of science whose names are well known in Europe, and from it thousands of students have been sent out to take part in engineering and other works necessitating the scientific application of the mechanical arts. Japan owes very much to that great educational work, and Viscount Hayashi said his people felt grateful for the assistance which Great Britain had given in this department.

THE London County Council School of Marine Engineering at Poplar, which was described in NATURE for October 19, 1905 (vol. lxxii. p. 623), was opened on January 24 by Sir William Collins, M.P. An address was delivered by Sir William White, K.C.B., who expressed a favourable opinion of the arrangements, equipment, and course of study provided in the new institute. He went on to describe the remarkable results attained during the last twenty years by a modest educational scheme which he

had conducted on behalf of the Shipwrights' Company of the City of London. Before 1888 there was no evening class in the Port of London where young men could obtain instruction in the science of shipbuilding. The Shipwrights' Company then undertook to establish and assist evening classes, which have been since carried out successfully and without a break in various parts of the East End. In these classes hundreds of young men have received valuable teaching, and the results have surpassed expectation; many of the students of the evening classes have proved themselves capable of taking the highest training in naval architecture at the Royal Naval College at Greenwich, and elsewhere, and not a few have secured positions of importance and responsibility in the Admiralty service, under the Board of Trade, Lloyd's Register of Shipping, and in private shipbuilding establishments. This object-lesson of what can be done with moderate expenditure, under careful and personal supervision, gives every reason for anticipating much greater benefits from the new institute with its ample means and adequate provision. Sir William White concluded by remarking that technical education for the rank and file as well as for the leaders and captains of industry is of great importance, and in providing the new school and equipping it on so generous a scale the London County Council has shown great wisdom as well as great liberality.

MEN of science have long urged the necessity for the introduction of scientific methods of inquiry and procedure into national administration, and their consistent advocacy culminated recently in the inauguration of the British Science Guild with the primary object of familiarising statesmen and others with the scientific spirit. The first president of the new guild, Mr. Haldane, is the Secretary of State for War in the new Government, and his speech on January 27 at a banquet of the Edinburgh University Liberal Association may well fill men of science with hope that a new era is near in which ideas and the results of scientific research will be taken into account in legislation and administration. Mr. Haldane insisted that national prosperity is not wholly a matter of fiscal policy. Answering the question, Is all well with us? he replied in the negative, because we are lacking in the ideas which science alone can give us, and consequently are lacking in the organisation of our industries. Knowledge, the expert, the spirit of science and organisation to permeate our people, our manufacturers, and workmen alike are all wanted. One of the ways in which the universities can assist the nation is in this direction. Mr. Haldane said his impression is that the Army would be the better for more help from the universities than it had been able to take from them. There are too few officers of the right sort, the thinking sort, like the men in the Engineers and in the Artillery, but of whom there are too few in the Cavalry and the Line. Mr. Haldane thinks he sees the beginning of a movement of this kind; and he hopes the university men will play a distinguished part in the future in obtaining that which is absolutely essential in making the Army an efficient army—a supply of scientifically minded officers and soldiers. The splendid fighting quality in the field which has distinguished the Army in the past, the quickness of eye that is born and that does not come is needed; but with it and behind it, whether in the hands of the general staff or of the commander himself, there must be a knowledge that can only come of the hard and patient discipline of the spirit.

THE cooperation of employers in the technical training of apprentices was a subject of discussion at the annual meeting of the Association of Technical Institutions held last week. A report upon this subject was issued recently by the association, and some of the results of the inquiry were stated in NATURE of December 21, 1905 (p. 188). In a contribution to the discussion, Prof. W. Ripper remarked that his own observation and experience has led him to believe that the unsympathetic attitude towards technical education which used to be so common among foremen and employers in this country is undergoing a change. The apathy and indifference towards educational improvement so general among apprentices and young people will be largely removed when they are made to realise that there is, as a rule, no promotion for them unless they are able to show that they possess educational as well as practical fitness for such promotion. This method of promotion is the one exclusively adopted in the Government dockyards, and the results of it have without doubt been highly satisfactory. In the race for commercial supremacy England, America, and Germany are each, probably, equally well equipped with the most up-to-date machinery and appliances. But these are tools merely. For the real element of success, for the intelligence and virility behind the tools, we depend alone upon the quality of the individual men from top to bottom of the industrial army; and especially do we depend upon the quality of the men at the top—the leaders—whose character, ability, foresight, judgment, power of organisation, and power of inspiration must ultimately determine the degree of success of the efforts of the whole. At present there is too often no connection whatever between the works and the technical school, no knowledge on the part of the employer of the quality of the youths in the colleges, who are available for suitable employment, and, on the other hand, no opportunity on the part of the youths to show possible employers what qualifications they possess, and what claim they have to recognition over the youth who has received no training. A closer relationship between employers and the teachers in technical institutions is therefore demanded in the interests both of public efficiency and of private well-being. In the discussion which followed the reading of Prof. Ripper's paper, Prof. Wertheimer said there is no doubt a steady, if not rapid, improvement taking place year by year. Firms—and the best firms, too—are recognising the desirability of getting into their employ young people whose intelligence has already been trained.

SIR WILLIAM ANSON delivered an address as president of the Association of Technical Institutions, at the annual meeting of the association held last week. In the course of his remarks, he said that the subject which most exercises both the local authorities and the Board of Education is the coordination of the studies which make up our system of education, and especially coordination in such a manner as to give to our technical institutions their proper place and to secure for them their utmost utility. There is no subject more intimately connected with the welfare of the people and the prosperity of our industries. We have paid somewhat dearly for our neglect of science in the past, and not merely for neglect of science, but of any conception of education which can be regarded as scientific or even as systematic. There is one form of error which touches more nearly the elementary schools. We have founded technical institutes, have multiplied libraries and laboratories, but have not taken pains to ensure that those to whom this instruction is offered are capable of taking advantage of it. Time and money are wasted in endeavouring to impart technical instruction to students who have forgotten such elementary mathematics as they ever knew, and who are unable to express their knowledge in their own language in an intelligible form. Everyone ought to know something of science, and everyone would be the better for learning the practical application of some branch of science. But we want the students in technical institutions to come to them able to take advantage of the opportunities which they afford, and not only this, but able to carry forward knowledge which they acquire; not merely to learn something and go away with no idea or intention of following up the instruction which they have received. An educational system may be devised in which all the parts are symmetrically fitted together, in which science pure, and science applied, language, literature, and history are all given their due place, and every arrangement made for the student to pass through courses appropriate to him under teachers fully qualified for their work. But even if these educational ideals are realised, it may be doubted whether we shall get what is wanted until there comes into existence a more widely diffused belief in education, in the value of a trained intelligence as well as of particular information, a belief that experience acquired with knowledge, and knowledge applied with intelligence, are better than that mere experience which is described in the common phrase "rule of thumb." As Sir John Wolfe Barry had said, "We want to see in Great Britain the

man of science installed in his laboratory in all important manufactories and encouraged to help in their development." Great employers have it in their power to advance the education of the people all along the line. Technical instruction in all its stages is a practical thing; and when it is realised that employers appreciate the instructed and intelligent student, then parents will begin to see that education has a practical value. The educational gospel should be "Believe, believe," not only or chiefly in machinery, in a curriculum, a laboratory, a library, but in the value of knowledge, of intelligence, of training, and when we have made this belief widespread an important step will have been taken toward the education of our people.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 14, 1905.—"Report on the Psychology and Sociology of the Todas and other Indian Tribes." By Dr. W. H. R. **Rivers.** Communicated by the Secretaries of the Royal Society.

An abstract of observations made chiefly on the Todas of the Nilgiri Hills. The psychological work deals chiefly with the senses, in only two of which is there evidence of decided difference between Todas and Englishmen. The former were less sensitive to pain, and showed certain deficiencies in the colour-sense, especially in the degree of relative sensibility to red and blue, a low degree of sensibility for blue being associated with defective nomenclature for that colour. Definite colour-blindness was found in 12 per cent. of the males, a frequency higher than has been recorded in any other race. Quantitative observations were made on two visual illusions, one of which, that of compared horizontal and vertical lines, was distinctly more pronounced in the Todas, while the other, the Müller-Lyer illusion, was present in a slighter degree. This difference is believed to depend on the difference in nature of the two illusions. Especial attention was paid to the variability of the individuals subjected to the tests, and it is shown that there is some evidence of correlation between the degree of general intellectual development and certain simple mental activities which can be tested by experimental methods.

The sociology of the Todas was studied by means of the genealogical method, and was found to have many points of resemblance with that of Malabar, and the view is advanced that the Todas at one time inhabited that district and are probably of the same race as the present inhabitants of Malabar, the Nairs and Nambutiris. A detailed record was obtained of the elaborate religious ritual of the Todas, and evidence is given that this religion has undergone degenerative changes. It is suggested that this is part of the general disappearance of a higher culture which the Todas brought with them to the Nilgiri Hills.

"On the Spectrum of the Spontaneous Luminous Radiation of Radium. Part IV. Extension of the Glow." By Sir William **Huggins,** K.C.B., O.M., F.R.S., and Lady **Huggins.**

In our second paper [1] we suggest "whether the β rays, which are analogous to the kathode corpuscles, may not be mainly operative in exciting the radium glow. On this surmise it would be reasonable to expect some little extension of the glow outside the limit of the solid radium itself. We are unable to detect any halo of luminosity outside the limit of the solid radium bromide; the glow appears to end with sudden abruptness at the boundary surface of the radium." We omitted to state that this conclusion was arrived at by eye observations. The radium was observed in the dark with a lens, and with a low-power microscope.

The earlier photographs of the spectrum of the glow were taken, for the purpose of comparison spectra, with the height of the slit reduced by shutters so as to be within the width of the exposed radium bromide, and, therefore, these photographs would not show whether the bright bands of nitrogen extend into the air beyond the radium. Subsequently photographs were taken with the whole height of the slit, and on these we find that all the bands of nitrogen do extend to some little distance outside the radium salt. Our attention at the time being directed to other phenomena of the glow, we did not examine the photographs to see if the nitrogen bands extended beyond the radium.

[1] *Roy. Soc. Proc.*, vol. lxxii., p. 410 (1903).

In a paper, dated August 22, 1905, F. Himstedt and G. Meyer [1] state that in their photographs of the spectrum of $RaBr_2$, the four nitrogen bands, 3577, 3371, about 3300, and 3159, extend beyond the radium salt, while the other less refrangible bands are not traceable outside the radium. In our photographs all the nitrogen bands project beyond the radium salt, the relative distance to which the extension can be detected in the case of each band being, as might be expected, in proportion to the strength of the impression of that band upon the photographic plate.

B. Walter and R. Pohl, in a paper dated September, 1905,[2] give an account of experiments made with the help of screens, which show that for a distance of up to about 2 cm. the air surrounding radium bromide has an action on a photographic plate.

On re-examining an early photograph, taken in 1903 for another purpose, which is described in our second paper,[3] in which the $RaBr_2$ was enclosed in a very narrow tube of thin glass, we find that the bands of nitrogen, which are strong within the tube, show no trace of extension on the plate beyond the tube. The exposure of this plate was seven days.

This experiment, which we have repeated recently with an exposure of fourteen days, shows that the luminosity of nitrogen in the near neighbourhood of radium bromide is not due to the kathode-like β radiation, for this passes freely through glass.

Two explanations may be suggested: first, that the active cause is the α rays; [4] or secondly, that the nitrogen molecules which encounter those molecules of the radium which are undergoing active changes are broken up into ions, which are projected outwards, and give rise to the glow of luminous nitrogen.[5]

Royal Astronomical Society, January 12.—Mr. W. H Maw, president, in the chair.—Photograph of comet *c*, 1905, taken at the Royal Observatory, Greenwich, on January 8: **Astronomer Royal.** The photograph showed the comet with a bright nucleus and a faint, straight tail extending about 2°. It was hoped that further photographs would be obtained after the comet had passed the sun.—The ring nebula in Lyra: E. E. **Barnard.** A careful series of measures of the positions of the stars about the nebula appeared to show that the star in the centre of the ring had neither proper motion nor parallax.—Mean areas and heliographic latitudes of sun-spots in the year 1904: **Astronomer Royal.**—Photographic reproduction of *réseaux* for star photography: H. **Bourget.** Specimens of the *réseaux* were shown on the screen.—Report on observations of Jupiter at Trincomali, Ceylon, 1904–5: Major P. B. **Molesworth.** Special attention was directed to the remarkable movement of the south tropical dark area in the neighbourhood of the great red spot. The motion of the area across the red spot bay was so rapid that it seemed necessary to assign some cause other than the actual transference of matter.—Measures of wide double stars: Rev. T. E. **Espin.**—Action of the wood of the dark slide upon photographic plates: Prof. H. H. **Turner.** The plates were negatives of the solar eclipse taken at Aswan by Mr. J. H. Reynolds, which were greatly injured by strong impressions of the grain of the wood of the dark slides in which they were placed after exposure. The same had occurred to Dr. Copeland's plates taken in 1898. It was stated that the wood of Mr. Reynolds's slides was very old, and various suggestions were made, but the real cause of this effect upon the plates still appeared obscure.—Lunar nomenclature: W. **Goodacre.**—Measures of the lunar crater Mösting A made at the Royal Observatory, Greenwich: **Astronomer Royal.**

[1] F. Himsted and G. Meyer, *Ber d. Nat. Gesells. Freiberg* vol. xvi. pp. 13–17.
[2] B Walter and R. Pohl, *Ann. de Phys.*, vol. xviii., p. 406.
[3] *Roy. Soc. Proc.*, vol. lxxii., p. 412.
[4] B. Walter, July, 1905, showed by means of absorption screens that the radiation from radio-tellurium can produce the ultra-violet light of nitrogen (*Ann. d. Phys*, vol. xvii., p. 367).
[5] The experiments described in our last paper showed that probably the β rays are not the operative cause of the nitrogen glow (*Roy. Soc. Proc.*, vol. lxxvi., p. 488).

Paris.

Academy of Sciences, January 15.—M. H. Poincaré in the chair.—The landing of aëroplanes: Bouquet **de la Grye.** A plan of arresting an aëroplane, and capable of keeping it horizontal during its descent, is described. It has been found to work in experiments on the small scale.—The n-rays: M. **Mascart** (see p. 325).—The influence of the reaction of the medium on the activity of amylase and on the composition of saccharified starch: L. **Maquenne** and Eug. **Roux.** The effect of the acidity or alkalinity of the solution on the hydrolysis of starch by malt has been recognised by other workers, without, however, the effect being quantitatively determined. The author shows that phenolphthalein is an unsuitable indicator to use for these experiments, methyl orange being better. He has found that for a rapid hydrolysis it is first necessary to neutralise the alkali of the starch, then to add to the malt a quantity of sulphuric acid equal to about 0·4 of that which would be required to neutralise it completely. Not only can the rate of hydrolysis be greatly increased by this treatment, but the proportion of maltose formed is also raised about 10 per cent. to 15 per cent.—Observations on the subject of the group C(OH) of the tertiary alcohols: Louis **Henry.** Tertiary butyl alcohol is converted by aqueous fuming hydrochloric acid into the corresponding chloride with great ease; by the substitution of the hydrogen atoms of the methyl groups by other elements the action of the hydrochloric acid is modified, the velocity of the reaction and amount of the ester formed being reduced, or the action altogether prevented. In the present paper the effects produced by the introduction of chlorine, cyanogen, and oxygen are discussed.—Some integrals of partial differential equations: E. **Goursat.**—A family of conjugated networks with the same congruence: E. **Merlin.**—The impossibility of negative waves of shock in gases: Gyözö **Zemplén.** A reply to the criticisms of P. Duhem on a former note on the same subject.—The conditions of establishment and application of progressive damping for the oscillations of road vehicles: A. **Krebs.** It is shown by a theoretical analysis of the problem that the friction of ordinary carriage springs ceases to be efficient when the sudden change of level is more than 2 cm. A new arrangement is described which satisfies the theoretical conditions for greater oscillations, and which has been found to work well in practice.—Photographic experiments on the action of the n-rays on an oscillating spark: C. **Gutton.** If the n-rays are allowed to fall on the primary spark of a Hertzian oscillator, the secondary spark diminishes. The present paper deals with the photographic registration of this effect.—The density of ice: A. **Leduc.** About 108 grams of water were frozen in each of the author's experiments. Well boiled distilled water gave a density of 0·9172, but it was clear that this number was too small, since in the upper part of the density flask small strings of separated air bubbles were visible. By repeatedly melting and freezing in a vacuum, the density was raised to 0·9176, and even in this case there was some evidence of traces of dissolved air. It is pointed out that the usual method of analysing the gases dissolved by water must be inexact, since all gas is not expelled by boiling.—The distribution of electric currents in a network: I. **Révilliod.**—A parhydric valve: J. de Rohan **Chabot.** A description of a new form of valve for preventing the return of water into the vacuum of a filter pump.—Correction to a note on the saline oxide of nickel: H. **Baubigny.**—The silicide of copper, and a new mode of formation of silicon soluble in hydrofluoric acid: Paul **Lebeau.** When the amount of silicon in a copper silicon mixture is raised above 10 per cent., a metallographic examination shows the presence of free silicon.—A silicide of thorium: O. **Hönigschmid.** This has been prepared by heating together a mixture of aluminium, potassium fluosilicate, and the double fluoride of thorium and potassium; the excess of aluminium is removed by treatment with potash solutions. The compound isolated, the chemical and physical properties of which are given, has the composition $ThSi_2$. The diazo-derivatives of the diamines: Léo **Vignon.**—The estimation of carbon monoxide in air by iodic anhydride: Albert **Lévy** and A. **Pécoul.** Although acetylene reacts with iodic anhydride, it does not interfere with the estimation of minute amounts of carbon monoxide in air, since a mixture of 1 part of acetylene in 10,000 parts of air gives no iodine.—The estimation of small quantities of chloroform in air and in blood or in aqueous solution: Maurice **Nicloux.** A combination of the methods of Dumas (the action of alcoholic potash on chloroform) and Mohr (chlorine titration in presence of a chromate).—The combustion of acetylene by oxygen: Paul **Mauricheau-Beaupré.** An examination of the products of combustion of the oxy-acetylenic blow-pipe flame showed that oxides of nitrogen and ozone were present, but no trace of carbon monoxide.—The direct proportionality between the cryoscopic point of a mineral water of the bicarbonate class and the composition of this water expressed as anhydrous monocarbonate: Lucien **Graux.** The half-bound carbonic acid is without effect on the freezing point.—Mixed crystals of alkaline nitrates: Fréd. **Wallerant.**—The alkaline rocks in the neighbourhood of Evisa, Corsica: M. **Deprat.**—The yield of urine: Henri **Lamy** and André **Mayer.** The vitelline of the egg: L. **Hugounenq.**—New researches on the oxidations produced by animal tissues in the presence of ferrous salts: F. **Battelli** and Mlle. L. **Stern.** Examples of the analogy between the oxidations produced by hydrogen peroxide in presence of ferrous sulphate and by animal extracts in presence of the same salt. The anomalous behaviour of the proteolysis produced by papaine: C. **Delezenne,** H. **Mouton,** and E. **Pozerski.**—The whitening of wheaten flour: E. **Fleurent.** The oxides of nitrogen are more favourable than ozone, the latter giving an objectionable smell to the flour.—Geology of the Peloponnesus: Ph. **Négris.**—An ancient volcanic chain to the N.W. of the Puys chain: Ph. **Glangeaud.**—Magnetic observations made at Sfax, Tunis, on the occasion of the total eclipse of the sun of August 30, 1905: M. **Dehalu.**

January 22.—M. H. A NEW INTEGRAL CALCULUS.

Integral Calculus for Beginners. By Alfred Lodge, M.A. Pp. xiii+203. (London: George Bell and Sons, 1905.) Price 4*s.* 6*d.*

"THIS is a sequel to the author's 'Differential Calculus,' and is intended for students of physics and mechanics who require a good working knowledge of integration and its more simple applications." Such is the claim put forward by Prof. Lodge in his preface. We naturally expect a book in which simple useful applications figure more prominently than lengthy theoretical investigations, and in this we are not disappointed. Moreover, a number of interesting features strike us as being particularly good, although a few others are capable of improvement.

The first of the good features is the insertion of the integration constant C in the elementary worked-out examples on integration. Its omission frequently leads a beginner astray. Another feature possessing many advantages is that the chapter on rational fractions is reduced to a minimum. The process of integrating a rational fraction with a denominator of high degree is not often required in actual practice. Moreover, the graph of such a fraction has infinite branches corresponding to the real factors of the denominator, so that unless the areas of these infinite branches are carefully discussed, by introducing the notion of the "principal value" of a definite integral, the result only enables us to find the areas of limited portions of the curves, for which approximate methods of quadrature would in many cases suffice. On the other hand, the mode of introducing the connection between integration and summation—a point on which Prof. Lodge rightly lays special stress (§§ 2, 43, 48)—will probably be regarded by most readers as not so satisfactory as it might be. Thus, to go no further, a relation on p. 4 is stated to be true to the first order which on p. 62 is shown to contain an error of the first order. This is the greater pity as the investigation of § 48 would, with the addition of a couple of lines, contain all that is necessary for a rigorous graphical proof, far shorter than that given in § 2; we hope this point will receive attention in future editions.

In reading the sections dealing with Simpson's rule and its modifications, one is surprised at the conservatism that prevails in the retention of a formula in which odd and even ordinates have unequal weight —a conservatism quite independent of the present book. When it is recollected that cutting off the first and last strips of a curvilinear area reverses the weights of the ordinates it will be seen easily that the trapezoidal rule, modified by suitable corrections for the two ends, may be made to give results quite as accurate as those of Simpson's rule.

Under applications of the calculus, we find areas, centres of mass, volumes and surfaces of revolution, and moments of inertia with especial reference to plane areas and their centres of pressure. The sections on differential equations contain what has for some time past been regarded as a standard elementary course on the subject, namely, the simpler equations of the first order and linear equations with constant coefficients. The study of the first integral of the equation $d^2y/dx^2=f(y)$ in connection with its kinematic interpretation, and the discussion of small oscillations in connection with the equation of harmonic motion, are good features. Finally, the chapter on the Gamma function has given Prof. Lodge an opportunity of saying something he wanted to say, and of saying it in his own way instead of cutting or drying it down to the requirements of a syllabus. It contains an interesting discussion of the extension of the conception of a factorial to negative and fractional arguments. It is much to be hoped that this chapter will encourage other writers of text-books to launch out into something new and original. This might to some extent help to save English mathematical teaching from sinking down to a uniform dead level of mediocrity, reminding one of an open, barren *veldt,* in which all the smaller hills have been levelled down by the steam-roller of the examination and the syllabus, and all high eminences have crumbled to the ground as a result of the starvation salaries paid to really competent mathematical teachers.

G. H. Bryan.

[Since the above was written I have had some correspondence with Prof. Lodge quite independently of the present review. The treatment of the summation of infinitesimals contemplated by him in the articles criticised above may be stated more clearly somewhat as follows:—Let $y=f(x)$, and let x increase from a to b by a series of increments dx. Then if dy denote the corresponding increment of y, the sum of the increments dy is *exactly* equal to $f(b)-f(a)$. Moreover, the "exact differential" dy becomes equal to the "differential product" $f'(x)dx$ when dx is infinitesimal, and *under this condition* we may put $f(b)-f(a)$, equal also to the sum of the differential products $f'(x)dx$. Also in all practical applications Prof. Lodge contends that what we really want is the sum of the exact differentials dy rather than the sum of the corresponding differential products $f'(x)dx$. This contention I believe to be correct, and if Prof. Lodge can re-write the articles once more —for he says that he has already repeatedly re-written them—and make it more clear that he is not merely giving an inaccurate reproduction of Todhunter's rigorous proof, but something quite different, his treatment may be made one of the many valuable features of his book. The method interests me greatly, and appears to be of sufficient general interest to justify the present explanatory note.—G. H. B.]

STIMULUS AND MEMORY.

Die Mneme als erhaltendes Prinzip im Wechsel des organischen Geschehens. By Richard Semon. Pp. xiv+353. (Leipzig: Wilhelm Engelmann, 1905.) Price 6s. net.

LITTLE as it may appear from the title, this work is really an inquiry into some of the remoter effects of stimulation. Thus, every stimulus applied to organic substance—whether that substance be nervous, or not nervously differentiated—produces not only its appropriate reaction, but also an altered condition of the substance itself, so that even when the immediate effect of the stimulation has subsided, the second "condition of indifference" is different from the first. The substance may now, for example, readily react to stimuli which before were insufficient to produce any appreciable effect, or it may respond to a stimulus connected only by association with the stimulus usually necessary. It pleases this author to read and group these facts anew, and to apply to them a terminology that will correspond with the novelty of the grouping. Hence he calls the enduring effect of the stimulus an *engramm*; the stimulus is said to operate *engraphically* on the substance, or to produce an engraphic alteration. Again, when stimulus B, differing in quality or quantity from stimulus A, still succeeds with the aid of the *engramm* in producing a reaction appropriate to A, it is said to operate *ecphorically*, or the new state of excitation is said to be produced by the *ecphory* of the *engramm*. Obviously ordinary memory may be brought under this wide class of phenomena, and the author might have used the term memory to describe these facts; but, to avoid misunderstanding, he has chosen the term *mneme* instead. Hence we read of such things as *mnemic* excitation, *e.g.* in the case mentioned above when stimulus B is applied.

The situation is well summed up on p. 89:—

"We recognise the presence of an engramm by the circumstance that for the discharge of the appropriate reaction the appearance of the original unaltered stimulus is no longer necessary, but the appearance either of the original stimulus altered quantitatively or qualitatively, or of a stimulus which works ecphorically on an associated engramm, or the expiration of a definite period of time (chronogenous ecphory), or finally the appearance of a definite phase of development in the continuous series of successive generations (phasogenous ecphory)."

Herr Semon on these lines proceeds to discuss the facts of acclimatisation and instinct, the inheritance of acquired characteristics, and the like, and to translate them into his peculiar language. Thus, when according to Mr. Claypole (as reported by Prof. Lloyd Morgan) young ostriches hatched in an incubator pick up food thrown before them only after someone has "dabbed" with his finger on the ground in their presence, our author's interpretation is that we have here the ecphory of an inherited engramm, an engramm the appropriate reaction of which is pecking; the ecphoric stimulus in this case is the return of the primary stimulus (pecking on the part of the mother hen) altered to some extent qualitatively.

The limits of space forbid a full account or discussion of many interesting questions raised by Herr Semon. In the second part of the book he deals with the mutual relations of engramms, their localisation, the mnemic conditions of excitation, and mnemic homophony. By mnemic homophony is meant "the process by which mnemic excitation and fresh original excitation are, so to speak, made to coincide, and by which each disagreement between the two produces a perceptive reaction." The third part discusses the reality of mnemic processes in "ontogenesis." In the fourth the author deals with various objections, and claims for *Mneme* that it is a necessary preservative principle which protects the transformations continually produced by the external world. He claims, also, that it helps us to an understanding of the law of which Haeckel is the unwearying exponent, viz. that the individual passes through the same stages of development as the whole species to which it belongs.

The author seems a competent reasoner and observer. His work is interesting and suggestive, and opens a fruitful field for discussion.

ECONOMY IN THERMAL POWER PLANTS.

Commercial Economy in Steam and other Thermal Power Plants as Dependent upon Physical Efficiency, Capital Charges, and Working Costs. By Prof. Robert H. Smith. Pp. xxiv+291; with numerous diagrams by H. Malcolm Hodson. (London: Constable and Co., Ltd., 1905.) Price 24s. net.

THE aim of this work is to deduce sufficiently accurate laws for determining the most efficient power plant when all-round economy is taken into account. For this purpose it is necessary to determine a standard of economy, and this is fully discussed in the opening chapter, where a coefficient is defined depending upon the value of the product directly and on the cost and time inversely. The application of this standard to measure the efficiency of production is applied to some examples, and the results of the analyses are considered in detail. After a discussion of the properties of steam, the efficiencies of engines and boilers, and questions of a kindred nature, the author proceeds to deal with the interesting question of the cost of various forms of thermal power plant.

The data for this chapter have been drawn from various sources, principally from makers' catalogues, and are exhibited in graphical form for heat engines by plotting capital or annual costs as ordinates against final cylinder volumes or brake horse-power as abscissæ. In this way very interesting relations are established, which can generally be approximately represented by straight-line laws with sufficient accuracy to form a fair estimate of cost. Thus for Crossley gas engines up to 500 horse-power with Dowson gas producers, the capital cost, including the building, is given as $300+10.8\,T$, where T is the

brake horse-power, while for a corresponding plant using Diesel oil engines the formula is $300+10\,T$. The annual costs for a year of 2700 working hours for these are stated as $200+3.7\,T$ and $110+2.9\,T$ respectively.

Steam engines are treated in like manner; thus in the case of a high-speed tandem compound engine the price is found to be represented by

$$140+0.05\,S-\frac{30,000}{240+S},$$

where S is the final volume of the steam in cubic inches swept out by the low-pressure piston per stroke. Formulæ are developed for boilers in terms of E, the evaporative power in pounds of water per hour, and the pressure, p, in pounds per square inch; thus the price of Lancashire boilers in pounds sterling is expressed by $110+(0.016+0.0003p)E$.

The information brought together in this section has evidently involved much labour, and it should prove extremely useful. The remaining half of the book is devoted to questions involving a considerable acquaintance with thermodynamics, in which the author introduces several new terms, such as "transpower" (p. 155), to signify the time rate of transmission of energy, "dynothermic coefficient" (p. 229), defined as the "ratio of resilience to heat transmission creating it."

Great stress is laid on the irreversible character of practical heat-engine cycles, and the author's views may be judged by his remarks on p. 178, where he says:—

"The conditions of life require rapid work, so that the sooner we give up worshipping reversibility as a fetish worthy to be aspired after and approximated to, the better will we succeed in engineering."

The dependence of maximum economy upon size, indicator diagram, initial and back pressure, working speed, and furnace temperature are all dealt with in detail, and combinations of the best values for effecting economy are considered by graphical methods.

The complex nature of the problems attacked make this part of the book decidedly hard reading, and the difficulty is much increased by the author's notation. The book is well illustrated by diagrams drawn by Mr. H. M. Hodson. E. G. C.

MATERIA MEDICA.

A Text-book of Materia Medica for Students of Medicine. By C. R. Marshall, M.D. Pp. xi+635. (London: J. and A. Churchill, 1905.) Price 10s. 6d. net.

THE compilation of a satisfactory text-book of materia medica is a somewhat difficult task, since the author should, at least in an ideal text-book, be equally conversant with the chemistry of drugs, the botany of those which are of vegetable origin and the therapeutics of all. Dr. Marshall has been singularly successful in preserving in this book an even balance between these various divisions into which the subject naturally falls.

The arrangement adopted, which differs somewhat from those commonly employed in text-books or materia medica, is to be commended. The first portion deals with the inorganic substances used in medicine, then a chapter is devoted to the synthetic products which have of recent years assumed so important a position as remedial agents, including antipyrine, phenacetin, sulphonal, &c., and finally about 300 pages are occupied with the description of drugs of vegetable or animal origin. The method of grouping these drugs is roughly that of the nature of the "active principles" they contain, so that the subject appears as a fairly coherent whole instead of as a set of isolated groups of facts, which is the case when the method of treatment adopted is that of the botanical relationships of the plants from which the drugs are obtained. The descriptions given of the various drugs of vegetable origin are clear, and though concise are sufficient for purposes of recognition, especially when used in conjunction with the carefully executed illustrations, which are one of the best features of the book.

In spite of the care which has evidently been taken, both in the actual compilation and in the "proof" reading, there are a few inaccuracies and doubtful statements still existent in the text to which reference may be made. It is not quite accurate to say that "no authentic case of antagonistically-acting alkaloids occurring in the same plant is at present known" (p. 6), since aconitine and aconine, which are stated (p. 330) both to occur in the root of *Aconitum Napellus*, have been shown to possess opposed physiological activities. Podophyllin is not, as suggested (p. 8), a "neutral principle," which, when used in the ordinary sense, means a single definite substance, but is a mixture of resins. The reference to the "theoretically possible number of terpenes" (p. 11) is misleading, since the number cannot be computed with our present knowledge of these bodies. Gums are not, as stated (p. 15), carbohydrates, and this statement does not harmonise with that given later (p. 16), that arabin, the chief constituent of gum arabic, is a mixture of salts of organic acids. Potassium hydroxide "can be handled with safety" (p. 111) is, to say the least, not a wise saying to place before students. Milk sugar (lactose) is wrongly described (p. 233) as not fermentable.

On general grounds exception may be taken to such a loose and carelessly worded statement as "on the differences in solubility of alkaloids is based the *principle* of standardisation" (*i.e.* of drugs and galenical preparations of these), and to such a sentence as "hyoscine and scopolamine have a somewhat *different* constitution *to* atropine and hyoscyamine."

Such blemishes as are referred to in the preceding paragraphs do not, of course, seriously detract from the excellence of the book taken as a whole, and it may be recommended to students as a safe guide to modern materia medica, at least in so far as this has received official recognition by the British Medical Council. T. A. H.

OUR BOOK SHELF.

Die neuere Entwickelung der Kristallographie. By Dr. H. Baumhauer. Pp. viii+184; 46 plates. (Brunswick: Vieweg and Son, 1905.) Price 4 marks.

THOUGH this sketch of the more recent developments of our knowledge of crystals will be of service to the crystallographic student, it is primarily intended for those physicists and chemists who require to make use of crystallographic methods in their own researches; detailed explanations of technical expressions and crystallographic ideas are therefore given.

The work is divided into six chapters. The first treats of the definition of a crystal, the law of zones, the law of rationality of indices, and the methods of crystallographic projection; an account is given of various fluid and viscous bodies which must now, according to the researches of Lehmann, Schenck, and others, be included in the same group with solid crystals. The second chapter shows that crystals may be distributed into thirty-two classes capable of reference to six systems, each class differing from the others in the elements of its symmetry. The third chapter explains the various methods by which the class of symmetry to which a crystal belongs may be ascertained, and thus treats of the determination of facial distribution by means of one-circle, two-circle, or three-circle goniometers, and the investigation of the physical or chemical properties, more especially optical anomalies, circular polarisation, pyroelectric behaviour, and the etch-figures developed on crystal faces as a result of solvent or chemical action; the last mentioned is a branch of crystal research to which Dr. Baumhauer has himself given much attention. The fourth chapter gives a discussion of the regular growths met with in crystals, and in this connection a detailed account is given of mimetic growths such as are observed in the case of the felspars. In the fifth chapter is a description of the development of crystal faces; an account is given of Goldschmidt's "law of complication" and of nodal points. The sixth and last chapter deals with isomorphism, morphotropy, topical axes, polymorphs, and the relations between the chemical formula and the crystal system of a substance. The observations of Prof. Miers relative to the vicinal faces of alum crystals, and the researches of Dr. Tutton on the relation between the chemical composition and the morphological and physical properties of a substance are specially mentioned. Prof. Baumhauer's long experience as a teacher has enabled him to give an account which is at once well up to date and of a readable character.

La Théorie moderne des Phénomènes physiques. Radio-activité, Ions, Electrons. By Prof. Augusto Righi. Pp. iv+125. (Paris: L'Éclairage Électrique, 1906.)

THIS is a translation from the Italian. The book is a good semi-popular account of recent physical developments, and is likely to be useful to those desirous of gaining a first acquaintance with them. Even original investigators will here and there glean useful hints or ideas.

Prof. Righi, we are interested to note, prefers the use of an electroscope of almost microscopic dimensions for detecting minute radio-active effects. A systematic inquiry into the best dimensions for these instruments is very desirable, and might be advantageously made either from a mathematical or from an experimental standpoint.

In one or two cases Prof. Righi quotes investigations of which the soundness may perhaps be doubted—for instance, the alleged occurrence of radiations from phosphorescent zinc sulphide capable of penetrating opaque bodies, and the determination of the velocity of Röntgen rays made by M. Blondlot. This last experiment depended on the action of the Röntgen tube on a minute electric spark. This action was afterwards attributed by M. Blondlot to the *n*-rays, and the objective existence of the *n*-rays is now generally discredited.

We have seen an English translation of Prof. Righi's book. The French translation is not, therefore, of special interest to English readers.

R. J. S.

Modern Lightning Conductors. By Killingworth Hedges. Pp. viii+119. (London: Crosby Lockwood and Son, 1905.) Price 6*s.* 6*d.* net.

THE subject of lightning protection is one of considerable importance to architects, and a book in which the existing information thereon is conveniently collated is therefore to be welcomed. Mr. Killingworth Hedges's long association with this very special branch of electrical engineering enables him to write with authority. The book may be regarded as a very useful work of reference on the subject, as it contains a summary of the recommendations of the lightning research committee of 1905, together with numerous extracts from the observers' reports on buildings which had been struck by lightning, which served as the basis on which the committee drew up its suggestions. These extracts are copiously illustrated and the faults in the details of the protection in each case are clearly pointed out. The book is enlivened by the last chapter, which gives several instances of peculiar results of lightning strokes.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Inventor of the Nicol Prism.

CAN any of your readers supply me with the dates of birth and death of William Nicol, the inventor of the Nicol prism? There is a tablet to his memory in the Wariston Cemetery, in Edinburgh, bearing an inscription drawn up by the late Prof. Tait. Strange as it may seem, though his fame is world-wide in optics, he is not even mentioned in the "Dictionary of National Biography," nor do I know of any memoir of him elsewhere.

SILVANUS P. THOMPSON.

Technical College, Finsbury, London, E.C., February 6.

Result of War affected by Soldier's Stature.

THE Japanese had an unquestionable advantage in the recent war as being smaller than the Russians; they were smaller targets for fire-arms. I wish to point out that it is possible to express this advantage quantitatively on the assumption, justifiable in modern war, that bullets are, on the average, uniformly distributed over the target presented by a man's body, also that a man presents a target proportional in area to the square of his height. The Anthropological Institute has kindly given me figures for the purpose; the average height of 2500 Japanese, 1260 of them being soldiers, was 1585 millimetres as compared with an average of 1642 millimetres for the average of 177,948 European Russian conscripts. The average Russian height thus exceeds that of the Japanese by about 3·47 per cent. The squares of the two average heights, representing, as I have said, the average targets offered by each to an enemy, differ therefore approximately by 7 per cent., so that the Russian fire was relatively ineffective to that extent.

Scintillations produced by the Electronic "β-Rays" emitted by Radium.

As the β particles emitted by the radio-active elements are analogous to the α particles, inasmuch that they may be considered as parts of the disintegrated atom, and not in any sense true rays, I have been conducting some experiments with the view of ascertaining if, in any circumstances, their action upon fluorescent screens caused recognisable scintillations. It will be obvious that if the radium used be placed too near the screen, the effects of the combined β and γ rays will produce a fluorescence sufficiently vivid to mask any scintillations due to the individual electrons which compose the β stream. In order to diffuse this action and allow the β particles to separate to such a degree that the flashes produced shall not overlap, recourse may be had to three methods :—

(1) Increasing the distance between the radium and the screen.

(2) Making the stream pass through material offering resistance to its passage.

(3) Reducing the quantity of radium used and "diluting" the action by mixing it with non-active substances.

I have tried these methods separately, and in each case have obtained results which were fairly satisfactory considering the difficulties attending this class of observation.

In these circumstances the screen, when viewed with a lens having a focus of about half an inch, was seen to be fluorescing with a faint glow, which was, without doubt, of an unsteady and flickering character.

The phenomena involved are delicate and difficult to observe, requiring the best possible conditions. It is very important that the eyes are thoroughly rested before the observation is made, but the fact that the glow is flickering and strongly suggestive of scintillations is, in my opinion, beyond dispute. After trying various combinations of the above methods, I have obtained results sufficiently decided to justify the statement that the screen was lit up by scintillations properly so called. A screen of zinc sulphide, so very excellent for viewing the scintillations produced by the α particles, does not give satisfactory results for the β stream.

Willemite and barium-platino-cyanide are both fairly good, the latter being rather the better of the two. I have obtained the best results with an ordinary X-ray screen. Having enclosed about 15 or 20 milligrams of radium-barium-bromide (1 per cent.) in a small glass tube, I placed over it a sheet of mica. Over this was placed a sheet of cardboard, and above this again, at a distance of about half an inch, was the screen. When the lens was focused on the screen, a dim fluorescence, due to the γ rays, was seen as a sort of background, on which were visible faint nebulous scintillations coming and going in a manner very similar to the scintillations produced by the α particles on a zinc sulphide screen. February 2.

The Effect of Food on the Colour of Moths.

IN a very interesting paper published in the *Journal of Economic Biology* (1905, No. 1), Mr. W. E. Collinge describes and figures a remarkable series of specimens of the magpie moth (*Abraxas grossulariata*, Linn.), obtained as the result of raising the larvæ on lettuce, the ordinary food being currant. The specimens all differed from the type in the direction of great loss of markings, the most extreme one representing the aberration known as *dohrni* or *deleta*. The same sort of effect has been produced on the tiger moth by G. Koch, as a result of feeding the larvæ on lettuce; and a good account of various experiments of the same kind is given by Dr. Vernon on pp. 288–9 of his work on "Variations in Animals and Plants" (1903).

The effect produced in the cases cited may be regarded as a sort of compulsory mutation, though we do not know whether it could in any case be inherited in such a manner that it would remain constant under different conditions. If the normal maculation, which has existed for countless generations, can be transformed in a single one by a new food-plant, it is not likely that the alternate type can be any better fixed.[1] The species must be regarded as potentially dimorphic, indeed, polymorphic, for other quite different aberrations occur. There arises, however, an interesting possibility. Mr. Collinge found that the insects were raised with difficulty on lettuce, and he doubted whether it would be possible to raise three successive generations exclusively on that plant. Suppose, however, that among many which fed on lettuce (or any unwonted food) a few were able to survive, and consequently a lettuce-feeding race became firmly established. Such a race would show the same marked differences from the type which appeared in the first generation, and it is not unlikely that at length it would be as difficult to get its members to live on currant as it originally was to get the currant-feeders to survive on lettuce. We should then have a lettuce-feeding form, very easily distinguished from the currant-feeding one, and nobody would hesitate to call it a distinct species. If it absolutely refused to feed on currant, the peculiar markings would be as fixed as in any species known.[1]

[1] In this connection, *cf.* "The Principles of Heredity," by G. Archdall Reid, 2nd edition, Appendix A, pp. 355–356.

These suggestions appear to have the more force from the fact that some of the lettuce-fed examples strongly recall *Abraxas sylvata*, which feeds on elm, and is universally considered distinct. This *A. sylvata* and its allies form a group of closely allied races in the Palæarctic and Oriental regions, and it would be extremely interesting to ascertain whether these several forms have different food-plants, and whether by changed conditions they can be derived from one another. Many years ago I had occasion to tabulate these forms, using the material in the collection of the British Museum, and in the hope that the matter may be taken up by some eastern entomologist I give here the brief table I made :—

A.—*Markings strongly developed.*
- (*a*) Expanse about 34 mm.; Europe, Siberia, &c. . . . *sylvata*, Scopoli.
  - (α) Markings stronger than type or darker; brown anal blotch more reduced; Japan, &c. . . *sylvata* var. *intensa*, Warren.
- (*b*) Larger; nearly always more than 40 mm. expanse.
  - (α) Markings strong and dark. China and Japan . . . *miranda*, Butler.
  - (β) Markings paler. India . . . *leopardina*, Kollar.
- (*c*) Still larger; expanse more than 50 mm.; markings rather pale.
  - (α) Markings more suffused. N. China . . . *plumbeata*, Warren.
  - (β) Markings less suffused. Silhet . . . *illuminata*, Warren.

B.—*Markings much reduced, but the brown blotches remaining well developed.*
- (*a*) Expanse more than 40 mm.; markings rather more developed than in *pantaria*. India . . . *paucinotata*, Warren.
- (*b*) Expanse more than 35 mm.; Europe . . . *pantaria*, Gn.
- (*c*) Expanse about 30 mm.; markings still more reduced. Europe . . . seasonal form *calaria*, Gn.

Since the physiological adaptation to the new food-plant is not really connected with the change of colour or maculation, it may frequently take place without any externally visible signs, or such signs may only arise after a long period. In this way we get "physiological species," which are no doubt more numerous than is generally supposed. T. D. A. COCKERELL.

University of Colorado, Boulder, Colorado, U.S.A., January 18.

A Correction.

IN the review of Prof. Fr. Czapek's "Biochemie der Pflanzen" (NATURE, vol. lxxiii. p. 192) I mentioned that I missed a certain paper by Schjerning. The author's name should have been Weis.

I also overlooked the reference to a paper by Cornevin. An index of authors' names would enhance the utility of the book. F. ESCOMBE.

[1] Pictet, quoted by G. A. Reid, reported that after several generations on a new food-plant, certain butterflies which had at first been modified reverted to the original type. Of course, the case I have imagined is one in which this does not take place, but experiment is needed to test the possibilities indicated.

A METRICAL AND PICTORIAL RECORD OF THE EARTH'S HISTORY.[1]

THE author of this curious book tells us that it is an attempt to present a sketch of the evolution of the earth on the nebular hypothesis, to note also subsequent sea and land movements, and successive appearances of life as revealed by the geological strata. The geological record of past life remains very imperfect; still, many additions, notably from strata in Egypt and North America, have been made in recent years, and studied in the light of the doctrine of evolution its revelations have become more intelligible.

Why the author should imagine that to describe in rhyme the history of our planet and its inhabitants, from the earliest times to the present day, would render the subject simpler and more attractive to the general reader it is hard to imagine; but still, precedents are not wanting in such works as Dr. Darwin's "Temple of Nature," Pope's "Iliad," Henry's "Latin Grammar," and a poetic history of England, to justify the author's contention that it is an appropriate form in which to present a cosmical and palæozoological work to the public.

We fully agree with him that the theme is deserving of a much higher form of treatment, and that some day a great poetic genius may take it in hand. We cannot help feeling, however, that prose would have best befitted the aim of the present work. The author has had both an academic and geological training, and knows, from the study of text-books, museums, and extensive travel, a great deal about the subject on which he rhymes, and he has had the advice and assistance of a great number of learned scientific men whose names are duly recorded in prose in the preface. But the feature which renders this work of special interest is its fine series of illustrations, fourteen being executed in colour-processes by E. Bucknall, L. Speed, C. Whymper, and others, and seventy-seven by tint process reproduction. These give animation and attractiveness to the work, and will doubtless induce many purchasers by the beauty or the weirdness of the subjects pourtrayed.

Commencing with the astronomical aspect of the earth, there is a very fine plate of "the great Nebula of Orion" (from the Yerkes Observatory, Wisconsin, U.S.A.), and of "a Spiral Nebula in *Canes venatici*," from the Lick Observatory, California.

There is a charming Cambrian marine scene with crinoids, star-fish, trilobites, and medusæ, drawn by Alice B. Woodward, and an equally attractive Silurian (submarine) view by the same artist. No fewer than thirty plates have been executed by J. Smit, who illustrated two little books by the Rev. H. N. Hutchinson called "Extinct Monsters" and "Creatures of Other Days." But having become accustomed to the life-like restorations of Mr. Chas. R. Knight, made under the direction of Prof. H. F. Osborn, of the American Museum of Natural History, New York, we feel that Mr. Smit's extinct animals are tamer and somewhat lacking in that high artistic merit which Mr. Knight's drawings possess. The coloured plates by E. Bucknall, L. Speed, and Charles Whymper are of a different order. E. Bucknall's cave-men carving on bones by firelight (p. 200), the "Neolithic Farmstead" (p. 214), the landscape in the Carboniferous period (p. 35), or his excellent conception of Sivatherium, a huge horned Pliocene giraffe, with a dappled hide like its long-necked modern descendant are most admirable. Lancelot Speed's primitive man and woman, although a clean shaven and washed, and intellectual looking couple, make a very good frontispiece. His Devonian, Triassic, and Eocene landscapes are also excellent and original. There is much merit and ability displayed in Chas. Whymper's Jurassic landscape with pterodactyls and a gavial hunting the duck-billed Ornithorhynchus, but we do not remember this monotreme occurring in any Jurassic rocks. The other novelties afforded by the book illustrations are from the facile pencil of Alice Woodward, as the Jurassic period (p. 62), with its ammonites and crustaceans; the restoration of *Diplodocus carnegiei* (p. 72); the Cretaceous sea-beasts (p. 83); Polacanthus, a reptile from the Isle of Wight reconstructed by Dr. Francis Baron Nopcsa (p. 88); restorations of various ancestral forms of elephants lately unearthed in Egypt; Mœritherium (p. 114); Palæomastodon (p. 114); and Tetrabelodon (p. 125); most remarkable of all those lately come from the land of the Sphinx is the Arsinoitherium (p. 120), a weird-looking herbivor, with quadricorn defences on its frontal bones and a full dentition of 44 teeth in its jaws not, however, in the ancestral line of elephants, nor perhaps of any living group, but *sui generis*. This, and the ancestral forms of elephants, are about to be published by the Trustees of the British Museum, as a monograph on the fossil mammalia, &c., from the Fayûm, Egypt, prepared by Dr. C. W. Andrews.

FIG. 1.—Polacanthus restored from skeleton found in the Isle of Wight, and now in the British Museum (Natural History). Total length probably about 25 feet. Reduced from "Nebula to Man."

The only other extremely novel restoration is that of the huge marsupial, Diprotodon (p. 172), the remains of which have been found in such profusion in the interior of South Australia by Dr. Stirling. The pic-

[1] "Nebula to Man." By Henry R. Knipe. With Illustrations by Ernest Bucknall, John Charlton, Joseph Smit, Lancelot Speed Charles Whymper, Edward A. Wilson and Alice B. Woodward. Pp xvi+252; with 16 coloured page illustrations and 57 tinted page illustrations. (London: M. Dent and Co) Price 21s. net.

ture of Pliocene horses by J. Charlton should also be noticed as a very spirited and excellent composition (p. 167).

FIG. 2.—Arsinoitherium (probably from 8 to 9 feet in length). From remains found in the Upper Eocene of Egypt. Preserved in the British Museum (Natural History) and in the Survey Museum, Cairo. Reduced from "Nebula to Man."

The following is Mr. Knipe's dedication of his work:—

To NATURE.

How fair, O Nature, are thy looks
  In these thy matron days:
And with what light a heart thou seem'st
To tread thy thorny ways.
  Man sees thee joying in thy life,
So full, so fresh, so free,
  As if thy toil in ages past
Had nothing been to thee.
  And well may he beneath thy spell,
Forget thy inner life,
  The waste and suffering in thy breast,
And never ceasing strife.
  Or if so be he needs must think
Of all the tumult there,
  He knows at least one end it has,—
  To make thee grow more fair.

It is not so much a matter of serious importance whether one reads patiently the carefully executed text in verse or turns with a disdainful smile from such lines as:—

"The whale-like Zeuglodonts that off these coasts,
In Eocene times pursued the finny hosts,
Are seen no more: but forms in tooth allied,
Though skulled more as the Dolphin, swim the tide."
* * * * * *

Suffice it to say that the book, as a whole, is admirably illustrated and must have cost the author a very large sum to produce. The pictures alone form an excellent guinea's worth, and will prove a real joy to the younger generation as well as to some of the elder, and there is no single picture in the book which has not been drawn expressly for the present work.

SOME MAMMALIAN TYPES.[1]

MR. RENSHAW, whose pleasant essays on African mammals are fresh in our memories, has in his new volume taken a wider field, and selected his types from the fauna of the whole world. They are still confined to mammalian forms, and this being the case it would perhaps have been possible to give these volumes a more original title than that adopted by Waterton for his famous essays published in the first half of the last century. But Mr. Renshaw's essays are decidedly original in the treatment of the subject. They deal not merely with the natural history of animals, but also with the history of our knowledge of them. Thus the history of the Addax antelope, inhabiting the great desert, is traced from the time of the ancient Egyptians and of Pliny to its modern re-discovery early in the last century; and that of the extinct northern sea-cow in connection with the adventures of the searchers after the North-west Passage.

Never before, indeed, has the history of mammalian forms been more attractively presented to the public. The history of the discovery of some of these grand forms of life is often a true romance of natural history, which, appealing strongly to the author, is graphically re-told by him; and his enthusiasm enables him to carry the reader with him to see in his mind's eye the country inhabited by the beasts he describes, and to feel some of the keen delight experienced by the hunter-naturalist when some such beautiful trophy as the sable antelope rewarded him for all his toil. He excels in describing the natural scenery—the setting—of the subjects of his essays; and writing of the Malay tapir, of "antediluvian appearance," conjures up a most realistic mental picture of the home of the Palæotheres, their ancient representatives, when in far-off days they roamed over swamps covering the present site of Paris.

The misconceptions which hang about the vampire bat in the popular mind are here cleared away, and the statement that it is difficult to stop the bleeding set up by it suggests a search of the salivary glands for any ferment that might hinder the coagulation of blood, and some interesting remarks thereon. Although it was discovered by Columbus, few people perhaps realise that a seal inhabits the warm waters

FIG. 1.—The Clouded Tiger. From "More Natural History Essays."

[1] "More Natural History Essays." By Graham Renshaw, M.B., F.Z.S. Pp. 243; illustrated. (London and Manchester: Sherratt and Hughes 1905.) Price 6s. net.

of the Caribbean Sea. The account of the Jamaican seal is all the more interesting because it seems likely to become extinct, possibly partly because it is one of those animals which, to preconceived ideas at all events, seem out of place. But in this connection we are reminded that there is also a Mediterranean seal, and that the leopard is actually as European as the brown bear. Another extinct animal which we are glad to have an account of is the Antarctic wolf of the Falkland Islands, finally exterminated by the sheep-farmers in self-defence; its possible introduction to the Falklands is discussed, and the question whether it was really distinct or merely a modified form.

These extracts will serve as a fair sample of the score of essays in the new volume. In the case of rare or extinct forms there is an indication of the known specimens now or formerly in collections. The value of photographs from life of rare, and especially of "threatened," species is emphasised by the author, who illustrates his essays with eighteen photographic plates. Even in the London "Zoo" it is not always easy to photograph an animal. The clouded tiger was under observation for five years before a satisfactory picture (which we are enabled to reproduce) could be obtained. O. V. A.

MINERS' WORM.[1]

THE dreadful disease known as ankylostomiasis, "tunnel disease," "cachexia of miners," or "miners' worm," is definitely known to be caused by the nematode worm *Ankylostoma duodenale*. The alarming spread of the disease in the mines of Hungary, France, Germany, and Belgium, and its recent introduction into some of the mines of this country, have necessitated a thorough investigation of the anatomy, development, and life-history of the worm. Already some 750 papers treating of the disease have been published, but only a few of these deal with the parasite itself, and still fewer with the details of its anatomical structure.

The splendid work before us now gives in full detail the gross and minute structure of the adult worm, but a second part is yet to come from the pen of the same distinguished parasitologist in which the development and life-history will be described. If the second part is as full of detail and as well illustrated as the first, the monograph will be the most complete account of any single species of animal that the world possesses.

The Ankylostoma was first discovered by Dubini in 1838 in the intestine of a peasant woman who died in the hospital at Milan, but it was not until some years later that he associated the worm with disease and published an account of it. Soon after Dubini's discovery the worm was found in Egypt by Pruner and by Bilharz. Dr. Looss considers carefully the suggestion that has been made that the worm Heltu mentioned in the Ebers papyrus of *ca* 1550 B.C. was Ankylostoma, and that the disease was known to the ancient Egyptians, but he comes to the conclusion that there is not sufficient evidence to support this suggestion.

The discovery of Ankylostoma in Brazil by Wucherer, and in other warm and tropical places, led to the belief that ankylostomiasis was peculiar to such climates, but the epidemic of "tunnel disease" among the workers in the St. Gothard Tunnel, and the recognition by Perroncito of its identity with ankylostomiasis, was the first indication of the serious part this worm was to play in the medical history of the present day.

Dr. Looss devotes some pages to a full discussion of the systematic position of the species and of the generic characters of this and the other genera of the family Agchylostominæ. I must confess to some disappointment that, influenced by the writings of Stiles, of Washington, the author has come to the conclusion that the genus must be written Agchylostoma. "I freely confess," he writes, "that I find the term *Agchylostoma* abominable," and throughout the monograph he uses the spelling Ankylostoma in roman letters and Agchylostoma in italics. It is extremely inconvenient, in any case, to restore an ancient and "abominable" spelling of a generic name, and it is to be especially deplored in a monograph of such value and importance as this one; but no rules of nomenclature can justify the course adopted of spelling a generic name in two distinct ways on almost every page.

The text consists of 140 pages of elaborate details of microscopic anatomy and histology, and the illustrations consist of ten plates of very beautiful drawings by the author, lithographed by Werner and Winter, of Frankfort.

The monograph was originally written in German, but has been translated with very great skill into English by Mrs. H. M. Bernard.

SYDNEY J. HICKSON.

[1] "The Anatomy of *Agchylostoma duodenale*, Dub." By A. Looss. Records of the Egyptian Government School of Medicine. Vol. iii. (Cairo: National Printing Department 1905.)

THE ROYAL COLLEGE OF SCIENCE.

MR. HALDANE and the other members of the departmental committee who for the last two years have been considering the important questions referred to them have earned the nation's gratitude. If the scheme they propose be carried out (and there is reason to believe that it will be, and at once) a great step forward will have been made towards providing that complete higher education the absence of which has made us the laughing stock of those countries the Ministers of which are more intelligent than our own. As the reporters are careful to show in their general review, many of our scientific industries are an easy prey in international competition as it is carried on to-day.

We give below extracts from the recommendations made in the final report, just issued, which will sufficiently indicate the proposals of the committee; many paragraphs have been omitted which deal with details.

The unification of the teaching which already exists or is already provided for at South Kensington, and the additional buildings, teaching and research suggested, will certainly provide an institution admirably designed to meet modern needs. But we are grateful to the reporters for more than this; they tell us with no uncertain sound that technical education must crown, and not replace, a general education, so the resources of the Royal College in the future will not be frittered away in trying to teach those who have not learned how to think and in turning out incomplete men. A sufficiency of professors is also postulated, so we may hope that researches as well as teaching will be intensified, both for professors and students.

Messrs. Wernher, Beit and Co. are happy endowers; it is not often that such munificence as theirs, which set the inquiry going, leads to such a rapid and satisfactory result. Their 100,000*l*. is now supplemented, roughly, by the interest of a million from the State, of another from the County Council, perhaps

almost another from the City Guilds, while the State and the Royal Commissioners for the Exhibition of 1851 provide between them some four or five acres of land to build on gratis!

Some paragraphs of the recommendations refer to a question which is academic in more senses than one—whether the new Royal College of Science shall be under the government of the University. Our own view is that the question should be left to settle itself. There certainly at present must be a special governing body to start it, and the one suggested seems all that can be desired. There certainly also at some future time must be a very close connection with the University; it is too early to define that time.

Extracts from Conclusions and Recommendations.

The conclusions at which we have arrived are:—

(1) That the position of this country makes further provision for advanced technological education essential.

(2) That the students, by whose advanced technological education the nation would profit, are not actually obtaining it to the extent which is desirable, and that this is due to:—

(*a*) The lack of facilities for instruction in certain important subjects.

(*b*) The absence of such coordination among existing institutions of technological education as would permit the concentration of the more advanced courses in a limited number of institutions.

(*c*) An insufficient appreciation, especially on the part of employers, of the value of such education.

(3) That the opportunities for research in our technological institutions are inadequate to the industrial needs of the Empire, owing not to any want of ability on the part of the professors, but to the fact that much of their time is frequently absorbed in the giving of comparatively elementary instruction in pure and applied science.

(4) That in any institution in which the highest technological education is given, the equipment should be adequate for the purpose, and the staff should include, at the head of the several specialised branches of the work, men of the first rank in their profession.

From this point of view the recommendations which we have the honour to submit in reply to our terms of reference may be summed up as follows:—

That the present combination of conditions at South Kensington points to the desirability of so utilising the resources there available, and of making additions to these, as to form on that site an institution of the highest standing, an institution which, with the staff, equipment, and students that it will command, would go far towards remedying the above mentioned defects.

In a preliminary report we inquired whether the Board of Education were in a position to inform us (1) that, if it were found possible to establish a scheme such as we had sketched in outline, they would be willing to allow the Royal College of Science (including the Royal School of Mines) to be brought into it under a common government and administration; and (2) that the existing Government contribution to the support of these institutions would be continued under the new conditions on the scale already made necessary by the provision of the new laboratories of the Royal College of Science.

The Board have replied to the first of these questions in the affirmative, and, in reply to the second, the Government have intimated that they will be prepared to bring the Royal College of Science and Royal School of Mines, including the new laboratories, into a scheme framed on lines approved by the Board of Education, in accordance with this report, and to make a grant of 20,000*l.* per annum in respect of the cost of staff and of the laboratory expenses, with provision in addition for certain other minor expenses.

The favourable disposition of the Government has greatly strengthened our position, and enabled us to obtain the support and cooperation which we consider necessary to ensure the success of the scheme described generally in our preliminary report.

The gift of a capital sum in excess of the minimum referred to (100,000*l.*) in the preliminary report has been secured.

The commissioners of the 1851 Exhibition are prepared, if satisfied with the scope and constitution of the new institution, to place at the disposal of its governing body the unoccupied portion of their estate at South Kensington.

The council of the City and Guilds of London Institute have indicated their willingness to bring the Central Technical College into a scheme to be framed to their satisfaction on the general lines we are able to recommend in this report.

The London County Council, on July 27, 1903, received a report from its General Purposes Committee upon the proposal contained in the letter which Lord Rosebery had a short time previously addressed to the chairman of the Council, and resolved to place on record its opinion that, subject to certain conditions being fulfilled (about which we may say we do not anticipate any difficulty), the Council would be well advised, when the time came, to contribute a sum not exceeding 20,000*l.* per annum towards the maintenance of the institution.

In our opinion a sufficient maintenance fund is assured, at any rate, to justify a commencement, if not to carry out the scheme we have in view as fully as we hope may be possible hereafter.

The main object is the establishment, at South Kensington, of an institution or group of associated colleges, of science and technology, where the highest specialised instruction should be given, and where the fullest equipment for the most advanced training and research should be provided, in various branches of science, especially in its application to industry, for which no sufficient provision already exists elsewhere. The number of the departments will be limited by the resources available, and at first a selection will have to be made among them. The scale on which the departments are established should be capable of gradual expansion with the increase in the number of students, fitted by preliminary education, to take advantage of the teaching and training contemplated.

The scheme should, in the first instance, and subject to necessary adjustments, include the work of the Royal College of Science, the Royal School of Mines, the Central Technical College, and departments to be established on the additional site at South Kensington.

Such being the scope of the new institution, it is necessary that we should make recommendations with regard to the composition and functions of its governing body. Of the relation of the new institution to the University of London, it is necessary to premise that we are agreed that it is desirable that the new institution should be established immediately, and that its organisation should proceed without delay, and there is substantial agreement among us that for this purpose a governing body of the character sketched in a subsequent paragraph should be at once appointed with power to take immediate action. We wish, however, to put in the forefront of our recommendations under this head a proviso that they should not be regarded as in any way intended to prejudice the future settlement of the question of the relation between the new institution and the University. This is a question on which divergent views are held.

We do not consider that the establishment of the new institution should be delayed pending a decision between these two views, or that the general lines of its organisation (except, possibly, as respects the governing body) should be regarded as other than permanent.

Subject to the proviso we have already made, we recommend that a governing body should be established consisting of forty members appointed as follows:—

Six by the Crown.

Four by the Board of Education.

Five each by the University of London, the London County Council, and the council of the City and Guilds of London Institute.

Four by the teaching staff of the new institution.

Two by the commissioners of the Exhibition of 1851.

One each by the Royal Society, the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Institution of Electrical Engineers, the Iron and Steel Institute, the Institution of Naval Architects, the Society of Chemical Industry, the Federated Institution of Mining Engineers, and the Institution of Mining and Metallurgy.

For the purposes of the new institution the governing body should have the entire disposal of the accommodation provided by the Royal College of Science, including the buildings in course of construction at South Kensington, the Central Technical College, and all buildings which may be erected on the additional site at South Kensington.

The site and buildings of the Royal College of Science, including the buildings in course of construction, should either remain the property of His Majesty's Government or be transferred to the governing body of the new institution, as His Majesty's Government may determine.

The site and buildings of the Central Technical College should, if and so long as they desire it, remain the property of the City and Guilds of London Institute, who should provide for their maintenance and repair.

The governing body should be incorporated, and subject to such special provisions as may be made by their instrument of incorporation they should receive and expend fees and other funds which may be assigned to the purposes of the new institution, they should appoint the professors and the other members of the staff, they should determine the departments and subjects of instruction, they should control the arrangement of the courses of instruction, and the award of diplomas, and they should make provision for the protection of students now in the constituent institutions and of the existing diplomas. Further, in each of the departments of the new institution the governing body should appoint a board, not necessarily consisting of members of their own body, and including members of the teaching staff and persons with practical experience of industrial requirements, to give expert advice with regard to such particulars connected with that department as the governing body may refer to them.

We recommend that it be an instruction to the governing body to enter into negotiations with the University of London, with King's College, and pending its actual incorporation, with University College, with regard to the coordination of the engineering work of these colleges with that of the new institution. We recommend that instruction in the higher branches of technology should, as far as possible, be concentrated at South Kensington. In the establishment of new departments we do not think it will be possible at present to go much beyond the various branches of engineering, with mining and metallurgy, though we hope provision may be made later for other subjects. We think the principal technical and engineering societies should be consulted as to the departments most requiring development and expansion, and as to the number of students for whom it is desirable to make provision in each department. In view of the character of the subjects which will, it may be expected, predominate on the South Kensington site, it must, we think, before long become a question whether the biological department of the Royal College of Science shall be retained there. As soon as this question becomes ripe for settlement, the provision to be made for that department will be a matter for negotiation.

We think that it may be found possible, even in the immediate future, to make arrangements for the establishment of departments dealing adequately with the greater number of special sections of applied science named. Thus it would seem that certain of these departments might be accommodated in the buildings of existing London institutions, while, for others, special accommodation would fall to be provided at once in the first additions to the buildings already available on the South Kensington site. For example, in view of the character and standard of the work now carried out by the Central Technical College, we think prominence should be given in the new institution to certain specialised developments of mechanical and electrical engineering.

We have already reported that we think a fully equipped central school of mines should be maintained, providing a full course of instruction in mining and metallurgy, especially in the mining and metallurgy of metals produced in India and the Colonies, but not found in workable quantities in the United Kingdom.

It should be borne in mind that the traditions and prestige of the Royal School of Mines and the associateship of that school are valuable assets, and we think care should be taken to preserve those traditions and that diploma.

In our opinion, accommodation should be provided in this department for 100 to 120 fully qualified students, *i.e.* fifty or sixty entries in each of the two years contemplated, so that forty to fifty students might be expected to pass out each year after successfully completing the course.

Vacation work under the guidance of school authorities, in districts where practical work is conducted, is a great and valuable feature of American and Canadian schools of mines. We think it would be advantageous for students of the Royal School of Mines to have one short period of practical mine surveying and of mining work generally, in a metalliferous mine, and another similar period of experience of the work of a coal mine.

No student should be admitted to any specialised technical department who has not received, either in the new institution itself or elsewhere, an adequate training of a technical and scientific character such as should be common to every branch of engineering. He should have spent two years on a course of instruction in science, such as he could obtain in a well organised college or technical institution, after having reached the standard of general education usually marked by university matriculation. An examination test should be imposed on all candidates for admission to the higher departments, except in the case of students who show, by some recognised qualification, that they have received the necessary preliminary training, and when there are more candidates for admission to a particular department than can be received, the best should be selected on a competitive basis.

The preliminary training to be given in the new institution should be of the kind which has just been referred to. It should consist of a course of two years' instruction in science, technology, and engineering, of such a character as the governing body consider the most suitable preparation for the specialised courses, and it should be, in the main, common to all students proceeding to advanced instruction in any department. We have already indicated our opinion that students who have not attained a certain standard of general education are not fitted to obtain the fullest advantage from the specialised instruction of the higher departments. We therefore think that evidence of this should be required before admission to the preliminary department.

NOTES.

SIR ALEXANDER B. W. KENNEDY, F.R.S., has been elected a member of the Athenæum Club under the provisions of the rule which empowers the annual election by the committee of three persons "of distinguished eminence in science, literature, the arts, or for public services."

PROF. ALBRECHT PENCK, of Vienna, has accepted the professorship of geography in the University of Berlin, vacant by the death of Prof. von Richthofen.

THE Nichols medal of the American Chemical Society for the year 1905 has been awarded to Prof. Marston Taylor Bogert, of Columbia University, for his researches on the quinazolines.

Science announces that Dr. C. D. Walcott has resigned the secretaryship of the board of the Carnegie Institution at Washington, and is succeeded by Mr. Cleveland H. Dodge.

A MEMORIAL tablet has been unveiled on the house, in Eisenach, in which the late director of Zeiss's works, Prof. Abbe, was born.

ARRANGEMENTS have been made to hold a hygiene exhibition in Dresden in the year 1909 under the directorship of Dr. Lingner.

FROM Tübingen the death is announced, on January 25, of Prof. W. Mayer, the director of the university pharmacological museum, and a member of the pharmaceutical examinations commission.

WE learn from *Science* that, in accordance with the recommendations of Prof. John B. Smith, a Bill has been introduced into the New Jersey Legislature appropriating 14,000*l.* a year for five years for the extermination of mosquitoes.

A REUTER message from Naples states that Vesuvius is still active. The lava has reached three places on the Vesuvian railway line, covering about 100 yards of the line at each point. The lava threatens the line at a fourth point, as well as the station of the funicular railway, which is no longer working.

THE Friday evening discourse at the Royal Institution on February 16 will be delivered by Mr. W. C. D. Whetham on "The Passage of Electricity through Liquids," and on February 23 by Prof. J. O. Arnold on the "Internal Architecture of Metals."

A GREAT mass of rock having a weight estimated at 70,000 tons at the lowest, and placed by some at half a million tons, fell at Cheddar Cliffs on Sunday night. The fall took place on the face of the cliff, and the disaster is attributed to quarrying operations.

THE *Electrician* states that the forty-fourth Congrès de Sociétés savantes will be opened at the Sorbonne on Tuesday, April 17. The congress will continue until Friday, April 20, and on the following day it will be concluded by a meeting in the great amphitheatre of the Sorbonne, presided over by the Minister of Public Instruction and the Fine Arts.

DR. LEWIS GOUGH has been appointed to assist Dr. Gunning in the management of the museum at Pretoria. The department for which he will be responsible will be that containing the fishes, the amphibia, and reptiles—groups of animals which were especially under his charge when he was an assistant in the museum at Strasburg. Recently Dr. Gough has been working at Plymouth on the plankton of the British Channel in connection with the British Marine Biological Association.

A SECTION of the Swedish Government is again anxious to impose an export duty on outgoing Swedish iron ores. A suggested duty of 20 öre per ton is desired, whilst the revenue accruing therefrom is to be applied to furthering the cause of the Swedish iron industry.

ON January 30 Mr. W. H. Cope, librarian to the University of Birmingham, was presented with an oak clock and a cheque by Prof. J. H. Poynting, F.R.S., on behalf of a number of present and past members of Mason College and of the University, on the twenty-fifth anniversary of Mr. Cope's appointment as librarian.

THE friends and pupils of the late Prof. A. Hilger, professor of pharmacy in the University of Munich, have decided to perpetuate his memory in the university town of Erlangen, the seat of his activity for many years. It is proposed to erect a handsome monument to the deceased man of science in the palace garden in front of Hilger's former laboratory. Communications and contributions are to be addressed to Dr. Späth, chief inspector of the Royal Analytical Institute, Erlangen.

THE twenty-fifth anniversary of the foundation of the Berlin Agricultural High School was celebrated on January 25; among those present were a number of relatives of the late Albrecht von Thaers, who is regarded as the reformer of agricultural teaching and of the science of practical agriculture in Germany. The rector of the school, Prof. Orth, chose as the title of his address "Agriculture up to the Time of Thaers."

WE learn from the *Times* that Sir Robert L. Patterson, who died at his residence near Belfast on January 29, was the second son of the late Mr. Robert Patterson, F.R.S. He was a member of the British Ornithologists' Union, and recognised as a high authority on Irish birds. For very many years he was associated with the Belfast Natural History and Philosophical Society, of which he was twice president for terms of two years each, in 1881 and 1894. He also took an active interest in the Ulster Fisheries Biology Association, of which he was a life member and a vice-president. He was a Fellow of the Linnean Society of London.

WE regret to record the death, in his forty-seventh year, of Mr. C. J. Cornish on January 30. Educated at Charterhouse and Hertford College, Oxford (of which he was a Fellow), Mr. Cornish at the conclusion of his college career was appointed an assistant master at St. Paul's School, a position he held until his death. He was the author of a number of articles in the *Spectator*, as well as of several books, bearing more or less closely on the popular side of natural history, and his innate love of nature, coupled with an agreeable style, made all his works a success. Among his best known books may be mentioned "Life at the Zoo" (1895), "Nights with an Old Gunner" (1897), and "The Naturalist on the Thames." In addition to these, he was editor of the "Living Animals of the World," published in parts by Messrs. Hutchinson, and was commissioned to write the "Life of Sir William Flower" by the relatives of that distinguished zoologist.

IN Natal, where a local committee has been formed to cooperate with the Imperial Cancer Research Fund (says the *British Medical Journal*), the question of the occurrence of malignant disease among such coloured races as inhabit the colony, and also among the lower animals, birds, fish, and reptiles, is being actively investigated. So far as is possible, the assistance of all practitioners of human and veterinary medicine has been secured, and endeavour has likewise been made to enlist the sympathies of naturalists and sportsmen. All specimens of suspected cancerous disease are being examined at the Government Laboratory, Pietermaritzburg, free of charge. The honorary secretary of the committee is Dr. W. Watkins-Pitchford.

SIR JAMES CRICHTON-BROWNE presided over the twenty-third annual dinner of the Sanitary Inspectors' Association on February 3. Sir W. Broadbent gave the toast of "Science and Art," and testified to the zeal with which sanitary inspectors discharged their duties in the battle against disease. The president, in proposing the toast of the "Sanitary Inspectors' Association," referred to the recent suggestions of Sir F. Treves that disease is beneficent, and passed on to consider the important work carried out by sanitary inspectors. The ravages of tuberculosis were particularly referred to as an example of the striking effects of sanitary reform. Sixty-seven years ago pulmonary consumption was annually killing 68,000 persons in England and Wales, or 3800 per million living. Since then there has been a gradual diminution in this death-rate, until now the number of deaths is 40,000 per annum, or a death-rate of 1200 per million. It has been estimated that by 1930 the disease may be almost unknown. It is necessary to have compulsory notification, universal disinfection of houses in which cases of consumption have occurred, and isolation and sanatorium treatment on a large scale.

THE inaugural meeting of the Mining and Geological Institute of India was held at Assansol on January 16. A brief account of the origin and objects of the institute was given by Mr. W. H. Pickering, chief inspector of mines, to whom, with Mr. T. H. Holland, F.R.S., director of the Geological Survey, the institute owes its inception. The object of the new society is the promotion of the study of all branches of mining methods and of mineral occurrences in India, with a view to disseminate information obtained for facilitating the economic development of the mineral industries of the country. Mr. Holland was elected president, and in his presidential address, we learn from the *Pioneer Mail*, he pointed out the true relations between the science of geology and the art of mining. He dwelt upon the advancement made in recent years in scientific mining, particularly emphasising the need of cooperation in publishing the results of practical and scientific investigations. On the following day the meeting was closed by a banquet, when Sir Andrew Fraser expressed the hope that the institute would succeed in bringing the officers of the geological department, inspectors of mines, and also *ex officio* honorary members, into touch with the practical men belonging to the mining community.

DURING his Administratorship of Dominica and of the Leeward Islands, Mr. Hesketh Bell has been very actively engaged in an inquiry which has served to show that the West India islands are not so frequently visited by disastrous hurricanes as has been generally believed, and that the Press reports of the occurrences are almost invariably greatly exaggerated. Tropical hurricanes are annual phenomena in the south-western portion of the Atlantic, but it is only when the centre of one passes over or close to an island that much damage is done on land. Mr. Bell has found that between 1800 and 1875 the British islands in the Leeward group were visited by only seven hurricanes. As the popular error on this subject, and the highly coloured accounts of the disasters, militated seriously against agricultural enterprise in the islands—having proved powerful factors against the investment of capital, and rendering it difficult for landowners to raise loans, save on very onerous terms—Mr. Bell has submitted the whole of the facts to a leading London firm of insurance brokers, and the result has been the completion of a scheme of hurricane and volcanic eruption insurance for the West Indies, the rates quoted being 30*s*. per cent. on buildings, cultivations, and crops of all kinds, except bananas (the ratio of risk in this case not being yet ascertained), and 10*s*. extra per cent. for risks against volcanoes. The huts and small tenements of the very poor are not included in the scheme. These fragile structures, naturally, are the first to go down before the storm, but they are easily re-erected. Properly worked and supported, the scheme should result in a decided reduction in the loss from hurricanes, and the islands generally should benefit from the greater confidence and sense of security of investors.

MR. L. M. LAMBE has sent us a copy of a paper on new species of tortoises, referable to the living genus Testudo and the extinct Bäena, from the Oligocene of the Cypress Hills, Assiniboia. The original paper is published in the *Ottawa Naturalist* for January.

THE two articles forming the contents of the third part of vol. lxxx. of the *Zeitschrift fur wissenschaftliche Zoologie* are of a nature which appeals to the specialist, and are too technical even to be summarised in our columns. In the one Mr. D. Tretjakoff treats of the front half of the eye of the frog and its development, while in the second Messrs. Otto and Tönniges discuss the development of the pond-snail commonly known as *Paludina vivipara*.

WE have received an advance copy of the report of the Yorkshire Naturalists' Union for 1905, in which the appointment of Mr. W. E. Clarke, of the Edinburgh Museum, as president for the current year is announced. The union is in a flourishing condition, and carrying on its work with the usual vigour. Ornithologists will be pleased to learn that arrangements have been made for the publication, in two volumes, of a work on the birds of Yorkshire, at the price of one guinea to subscribers.

IN a pamphlet issued by the Government Press at Calcutta, Mr. E. P. Stebbing describes certain bark-boring beetles which are inflicting much damage on the pine-forests of the Zhob district of Baluchistan. Chief among these is a species of the genus Polygraphus, which is described as new under the name of *P. trenchi*. Large numbers of dead and dying pines are to be seen in the forests, and it is considered probable that they are on the increase.

THE mode in which lungless (and gill-less) salamanders breathe forms the subject of investigations undertaken by Miss Seelye on *Desmognathus fuscus*, the results of these being published in a recent issue (vol. xxxii., No. 9) of the *Proceedings of the Boston Society of Natural History*. From this it appears that respiration is effected by means of the combined action of the mucous membrane of the pharynx and œsophagus, regulated by breathing movements of the nose and mouth, and of the skin.

A COPY of the "Naturalists' Directory" for 1906–7 has been received. While its usefulness cannot be denied, this little work stands in sore need of editing. To mention only a few instances, we find the names of the late Lieut.-General MacMahon, Dr. W. T. Blanford, and Mr. H. B. Medlicott figuring in the list of geologists (Dr. Blanford also in the zoological list), while the Duke of Bedford is referred to merely as an "F.L.S.," instead of as president of the Zoological Society. Expert assistance should be engaged before another edition is issued.

THE habits and distribution of the "false scorpions," Pseudoscorpionidæ, and more especially those of the species *Chelanops oblongus*, are discussed by Dr. Berger in vol. vi. of the *Ohio Naturalist*, the paper being reprinted as a Bulletin of the Ohio University. A figure and description of the curious "moulting-nests" of Chelanops are given. These, it seems, are not constructed by the female parent for her entire brood, but are made singly by each immature individual when the time for changing its coat arrives.

DEVELOPMENT and embryology from the evolutionary standpoint form the key-note of the contents of the first number of *Biologisches Centralblatt* for the current year, Mr. F. Dahl contributing a paper on the physiological importance of breeding-selection in its widest sense, as exemplified by spiders of the family Lycosidæ, while Mr. R. Kossmann emphasises the importance of favourable variations in influencing breeds and species, and Mr. Henriksen, in the first part of a dissertation on development from the functional point of view, urges that everything in nature tends towards a state of equilibrium peculiar to itself. In the last named article the author states he will "endeavour to show that the theory of the structure of germ-plasm [proposed] by Weismann is un-

necessary, and when worked out in details is quite absurd, and that we have no right to claim that the egg is some kind of a microcosm of the ontogeny and a short recapitulation of the phylogeny of the organism into which it develops.'

IN the course of a paper on phosphorescent marine animals, published in the January number of the *Zoologist*, Prof. McIntosh states that there are four distinct modes in which the light is produced. First, there may be special cells which secrete, in certain circumstances, phosphorescent mucus. Secondly, special cells may be phosphorescent without the emanation of any visible secretion. Thirdly, light may be emitted without any differentiation of tissue under nervous action. Fourthly, the phosphorescence may be due to light-emitting bacteria. One of the most striking features connected with phosphorescence is the simplicity of the mechanism by which it is produced and the entire absence of heat. "Thus," writes the author, "the light of a firefly, or a Pholas, has no sensible heat, whereas a temperature approaching 2000° F. would be necessary to make it by the usual processes, except the Geissler tube. So impressed were Prof. Langley and Mr. Very with this feature that they contrast it with the enormous waste in all industrial methods of producing light. . . . The authors, in view of this remarkable light without heat of the animals just considered, are of opinion that there is yet hope of obtaining an enormously greater result than we do now in the production of light."

BULLETINS Nos. 31, 32, and 33 (May and June, 1905) of the Bureau of Government Laboratories, Manila, have reached us. Bulletin No. 31 contains notes on a case of hæmatochyluria with observations on the embryo nematode, *Filaria nocturna*, by Drs. Wherry and McDill, and a research on the indol and cholera-red reactions by Dr. Wherry. Bulletin No. 32 deals with amœbic dysentery and amœbiasis, three articles being contributed by Drs. Strong, Thomas, and Woolley and Musgrave. Bulletin No. 33, by Dr. Herzog, records further observations on fibrinous thrombosis in the renal vessels in bubonic plague. The bulletins are well printed and well illustrated, and contain contributions of importance to medical science.

THE *Bulletin of the Johns Hopkins Hospital* for January (xvii., No. 178) is an excellent number. Dr. Harvey Cushing contributes an interesting and well illustrated article on Dr. Garth, the "Kit-Kat" poet. Garth was the single medical member of the famous Kit-Kat Club, and besides being distinguished in his profession and delivering the Gulstonian lectures and Harveian oration at the Royal College of Physicians, London, published many poems, the most important of which is "The Dispensary." Born in 1661, he died in 1718, and is buried at Harrow. Other articles are the relationship of the State to the tuberculosis question, by Dr. John Foster; a method of estimating the opsonic content of the blood, by Drs. Simon and Lamar; tropical splenomegaly, by Drs. Musgrave, Wherry, and Woolley; reports of societies, reviews, notes, &c.

THE Bulletin of the Department of Agriculture, Jamaica, for December, 1905, contains articles on rubber cultivation relating the progress made in Ceylon and south India, also a caution to planters with reference to the appearance of a cocoa disease caused by the fungus *Phytophthora omnivora*.

FROM the review of the teak timber trade in Burma, contributed by Mr. T. A. Hauxwell to the *Indian Forester* (November, 1905), it is seen that in the last fifteen years imports from Burma into Europe have diminished about 50 per cent., and prices have risen from 11*l*. to 15*l*. per ton; imports to India, where the standard of requirement is lower, show only a small decrease. The timber is extracted either by Government agency or by private lessees, the advantages in the latter case being that all marketable produce is extracted, and that the lessees have to share the risks, in connection with which the cost of elephants is a serious item.

IN the British West Indies, Jamaica easily leads the way in the cultivation of tobacco, but Trinidad also received an award at the recent Colonial and Indian Exhibition, and it is probable that good results may be obtained in certain parts of the other islands. A useful handbook to the cultivation and curing of tobacco has been issued by the Imperial Department of Agriculture as No. 38 of the pamphlet series. Mr. T. J. Harris gives a detailed and practical account of cultivation in the open and of curing the leaf, based on his former experience at the Hope Gardens, Jamaica, and Mr. W. N. Cunningham, who succeeded him, writes on tobacco-growing under shade.

OUR knowledge of the manner in which plants can receive external stimuli has been greatly extended by recent work, notably by the researches of Prof. Haberlandt. It is interesting to find that Prof. Schwendener has recorded his views on the subject in *Naturwissenschaftliche Wochenschrift* (January 2). In connection with the statolith theory of geotropism, a neat experiment is adduced as proof that can easily be put to the test. Ordinarily, if the root of a seedling is placed horizontal, curvature will ensue only after a definite lapse of time; assuming that starch grains take some time to react, it may be possible to reduce the interval by shaking or tapping the root. *Fiat experimentum.* The article also discusses the focusing action of certain epidermal cells of the leaf, and the mechanical feelers in the shape of hairs or papillæ that are possessed by insectivorous plants, the stamens of Berberis, and of the Cynareæ.

IN the *Proceedings of the American Academy of Arts and Sciences* for December, 1905, Mr. A. L. Rotch gives an account of the first observations with registration balloons in America. Although the successful experiments at Blue Hill led to the extensive use of kites for meteorological observations in other countries, unmanned balloons were not employed in America until 1904, when the author was enabled to make a series of four ascents at St. Louis in September of that year; at the maximum height, $10\frac{1}{2}$ miles, a temperature of $-62°.5$ F. was recorded. Another series of ten ascents was made in the latter part of November and the first part of December, mostly after sunset, to avoid possible effects of insolation. Two of these balloons travelled with a mean velocity of more than a hundred miles an hour. An extreme height of nearly 10 miles was attained, with a temperature of $-72°.4$ F.; and a reading of $-76°.2$ was once recorded somewhat below 7 miles. In order to continue these observations during the winter, Mr. Rotch made a further series of nine ascents during the latter part of January, 1905. On January 25 the extraordinarily low temperature of $-111°$ F. was registered at the height of about 9 miles, during the prevalence of a high barometric pressure at the ground. A complete publication of the results will be made in the Annals of the Astronomical Observatory of Harvard College.

An interesting pamphlet on the climate of St. Moritz has been published by Dr. A. Nolda, resident physician, with the collaboration of Mr. C. Bührer, director of the meteorological station at Montreux. The object of the paper is to show the claim of St. Moritz to be considered as a desirable health resort, and the meteorological statistics in support of this view are taken from those published by the Swiss Meteorological Institute in 1890–1 and 1900–4 inclusive; they are therefore entirely trustworthy. The village of St. Moritz is in the valley of the Upper Engadine, and the meteorological station has an elevation of 6040 feet. The characteristic features claimed for the station are:—a dry air, clear sky, high solar radiation, low humidity and rainfall, and almost complete immunity from summer and winter fogs; these advantages seem to be fully borne out by the official meteorological reports. The mean monthly temperatures are:—January, 19°·7 F.; July, 53°·8; the mean monthly extremes are:—January, −2°·5, 39°·7; July, 39°·9, 72°·7; the absolute extremes:—January, −15°·1, July, 76°·8. The mean annual humidity is 67 per cent.; on some days the atmospheric moisture falls to a point unknown in the lowlands of temperate latitudes; in 1900–4 instances are recorded of 10 per cent. to 16 per cent. The mean annual rainfall is 35·2 inches; rain and snow fall on an average on 128 days, and if we deduct the days when less than 0·04 inch fell, only 104 really rainy days remain. Compared with other places this is a very small number.

A copy of the *University of Colorado Studies* (vol. iii., No. 1), has reached us, containing brief historical, literary, psychological, and sociological articles by members of the university staff, a paper on extinct glaciers of Colorado by Mr. Henderson, and contributions to the natural history of the Rocky Mountains by Prof. T. D. A. Cockerell, in which several new insects and plants are described.

We have received reprints, from the Bulletin of the Museum of Comparative Zoology at Harvard (Geological Series, vol. viii., Nos. 1 and 2), of two papers by Prof. W. M. Davis. One, on the Wasatch, Canyon, and House Ranges, Utah, is a continuation of a paper on the mountain ranges of the Great Basin. The other deals with the glaciation of the Sawatch Range, Colorado.

The *Engineering and Mining Journal* of New York for January 6 contains carefully estimated statistics, compiled by prominent authorities, of production of the more important ores, minerals, and metals in the United States during 1905. The productions of iron, copper, lead, zinc, gold, and silver have all increased over 1904, and the outputs have been the highest recorded.

The introduction of reinforced cement marks a new epoch in the history of building, and an interesting account of some of the results achieved is given in the *Journal of the Franklin Institute of Philadelphia* for January. One of the most remarkable applications is the use of reinforced cement for the construction of dams. This method of building a permanent masonry dam at a comparatively low cost has already rendered financially practicable the utilisation of many water-power sites which otherwise would have been neglected.

In the *Bulletin de la Société d'Encouragement* of December 31, 1905, Dr. L. Guillet gives the results of a careful study of the nickel-vanadium steels. He prepared at the Imphy Steel Works nickel-steel alloys containing 0·2 per cent. and 0·8 per cent. of carbon, and of each series he selected a pearlitic steel, a martensitic steel, and a γ-iron steel, to which he added vanadium in proportions varying from 0·2 per cent. to 7 per cent. The effect of the addition of vanadium is to increase the elastic limit, very considerably in the case of the pearlitic steels. In other cases the increase is insignificant.

We have received from Mr. C. F. J. Galloway a useful paper contributed by him to the *Proceedings of the South Wales Institute of Engineers* (vol. xxiv., No. 6). It describes an application of the Brandt carriage and hydraulic column, successfully employed with hydraulic rock drills in the Simplon Tunnel, at a colliery in South Wales in conjunction with compressed-air rock drills. It proved one of the simplest and best forms of carriage for rock drills hitherto used. Full details of the work done and of the cost of the whole equipment are given.

In the *Transactions of the Institution of Engineers and Shipbuilders in Scotland* (vol. xlix., part iii.) there is an interesting paper by Mr. R. M. Neilson on the evolution and prospects of the elastic fluid turbine. Steam is not the only possible elastic fluid for a turbine; and the much greater ranges of temperature with the same range of pressure obtainable by the employment of other fluids instead of, or in conjunction with, steam deserve serious consideration. Much time has been spent on matters relating to elastic fluid turbines, and a large proportion of it has been devoted to inventions intended to be of a revolutionary nature with little knowledge of what had already been tried by others. The historical sketch of elastic fluid turbines given by the author is consequently most instructive. After an account of the early machines deserving the name of turbine, he describes and illustrates the turbines of Kempelen (1784), Gilman (1837), Wilbrow (1843), Wilson (1848), Fernihough (1850), Wertheim (1877), and De Laval (1882, 1889). The descriptions given of the turbines at present constructed show that although they differ among themselves very considerably, there is a visible tendency of the different types to approach each other. The preliminary experimental stage of the gas turbine has not yet been passed, and it cannot at present be said whether or not it ever will. An efficient gas turbine, which is a turbine both as regards the motor and the pump, seems to depend upon the obtaining of an efficient turbine compressor, or other form of rotary pistonless compressor. In order to determine whether the gas turbine had any reasonable chance of success in the near future, experimental research was needed as to the losses in pneumatic compression to high pressures, the expansion of hot gases in divergent nozzles, the transference of heat from gases to metals at high temperatures and very high velocities, and the oxidation of turbine blades when exposed to the action of air, steam, and carbon dioxide at high temperatures.

In several notices in these columns attention has been directed to the necessity of investigating mathematically the motions of aëroplanes and aërocurves as affording the only effective method of dealing with the problem of stability. A remarkably complete investigation on these lines is given in the *Revue d'Artillerie* for October and November, 1905, by Captain Ferber, who has been assisted in some of the calculations by M. Maillet. The method of treating the problem of longitudinal stability by considering the small oscillations about a steady state had been previously worked at (Bryan and Williams, *Proc. Roy. Soc.*, vol. lxxiii.), but owing to the appointment of the second of these authors to a research studentship, want of time rendered further progress impossible. The problem was then taken up by Captain Ferber, of the French

Artillery, who has given a masterly discussion of not only longitudinal but also lateral stability, and has arrived at a large number of important simple and practical conclusions relating to both the conditions of stability and the trajectories of aëroplanes the motion of which is stable. The paper constitutes by far the most important recent advance in the study of artificial flight.

MESSRS. PERCIVAL MARSHALL AND CO. have published a popular essay entitled "Electric Power. What it is and what it can do," by Mr. Alfred W. Marshall. The price of the pamphlet is 3*d*. net.

MR. NASARVANJI JIVANJI READYMONEY has issued a revised edition of his "Nature-history Museum and Descriptive defining Nature-history Tables," the first edition of which was noticed in our issue for March 30, 1905. Several changes and additions have been made in this painstaking piece of work.

Nos. 16, 17, and 18 of "Materials for a Flora of the Malayan Peninsula," by Sir George King, F.R.S., and Mr. J. Sykes Gamble, F.R.S.—which Messrs. West, Newman and Co., of Hatton Garden, are reprinting from the *Journal of the Asiatic Society of Bengal*—have been received. In addition to an account of the rubiaceous genus Psychotria, the first fasciculus contains descriptions of the Malayan members of eleven natural orders, including 48 genera and 81 species, of which two genera and 17 species are new to science. The second of the present parts describes five natural orders, Myrsinaceæ, Sapotaceæ, Ebenaceæ, Styraceæ, and Oleaceæ. These five orders comprise 24 genera and 221 species. There are no new genera, but the number of new species reaches 103. The last of the three instalments deals with nine natural orders containing 53 genera and 150 species, none of which are described for the first time. Among the orders of which accounts are given may be mentioned Boragineæ, Convolvulaceæ, Solanaceæ, Scrophulariaceæ, and Lentibulariaceæ. When all the fasciculi are available, we hope to review the complete work.

THE Cambridge University Press is publishing, under the title of "Cambridge Tracts in Mathematics and Mathematical Physics," a series of short works on various topics in pure mathematics and theoretical physics. The chief purpose of the undertaking is to assist in the maintenance of a high standard in English mathematical teaching by the continued infusion of new methods and more accurate modes of treatment, and by the extension of knowledge of recent mathematical research. The first of the series, a tract on "Volume and Surface Integrals used in Physics," by Mr. J. G. Leathem, has already been published, and a second, on "The Integration of Functions of a Single Variable," by Mr. G. H. Hardy, will be issued very shortly. The Press has also ready for immediate publication a new and revised edition, in one volume, of Prof. A. E. H. Love's "Treatise on the Mathematical Theory of Elasticity," and a third edition of Prof. Horace Lamb's "Hydrodynamics."

THE fourth year-book, that for 1905, of the Carnegie Institution of Washington has been received. The titles alone of the publications bearing upon the work done under grants from the institution fill eight closely printed pages, and it is impossible here to do more than direct attention to a few of the researches of outstanding importance. Prof. G. E. Hale, as director of the solar observatory at Mount Wilson, California, provides an excellent illustrated account of the astrophysical work done at Mount Wilson under his supervision. Prof. Lewis Boss, director of the Dudley Observatory, Albany, New York, describes his investigations of stellar motion. Mr. Charles B. Davenport, who is in charge of the station for experimental evolution at Cold Spring Harbour, New York, classifies the work in progress there, which is largely what he describes as of the "time-consuming" order, and gives a full report, with illustrations and results, of the experiments conducted during the year. Marine biology is well represented in the year-book by Mr. A. G. Mayer's account of what has been accomplished in connection with the laboratory at Tortugas, Florida. This report includes contributions from the numerous experts working in the laboratory. Several investigators were at work in the Desert Botanical Laboratory, Tucson, Arizona, and substantial progress in numerous directions was made during the year. Prof. T. C. Chamberlin, of the University of Chicago, continues his contributions to solutions of the fundamental problems of geology, and gives a full discussion of the deformations of the earth and of climatic oscillations. Mr. Bailey Willis, of the U.S. Geological Survey, describes his geological studies in Europe, and his attempts to determine the geographical condition of each continent at successive geological epochs. The magnetic survey of the North Pacific Ocean, undertaken by the U.S. Department of Research in Terrestrial Magnetism, and carried out by Mr. J. E. Pratt's party in the *Galilee*, is described by Dr. L. A. Bauer. These annual reports should be a source of gratification to Mr. Carnegie, and it is to be desired that wealthy men in this country could be led to follow an excellent example in the direction of encouraging scientific research and providing for the publication of results.

OUR ASTRONOMICAL COLUMN.

COMET 1905*c* (GIACOBINI).—The following is a continuation of the ephemeris published in No. 4067 of the *Astronomische Nachrichten* by Herr A. Wedemeyer:—

Ephemeris 12h. M.T. Berlin.

1906	α (true) h. m. s.	δ (true) ° ′	log r	log Δ
Feb 8 ...	23 31 16 ...	−21 9 ...	9·7704 ...	0·0694
10 ...	23 49 14 ...	−19 40 ...	9·8058 ...	0·0755
12 ...	0 5 58 ...	−18 7 ...	9·8379 ...	0·0830
14 ...	0 21 33 ...	−16 33 ...	9·8672 ...	0·0918
16 ...	0 36 3 ...	−14 59 ...	9·8942 ...	0·1016
18 ...	0 49 32 ...	−13 26 ...	9·9192 ...	0·1123

The accompanying chart shows, approximately, the apparent path of the comet among the stars from

FIG. 1.—Apparent path of Comet 1905 *c* (Giacobini), February 7–18, 1906.

February 7 to February 18, according to the above ephemeris.

Although still fairly bright, the comet is a difficult object

owing to its close proximity to the sun, and should be looked for immediately after sunset in the south-west quadrant, near to the horizon.

COMET 1906a.—Numerous observations of the new comet discovered by Mr. Brooks at Geneva, U.S.A., have been made, and from the positions determined on January 28, 29, and 30, the following elements and an ephemeris, of which a part is given below, have been calculated by Messrs. Crawford and Champreux:—

Elements.

T = 1905 Dec. 19·47 G.M.T.

$$\left.\begin{aligned} \omega &= 86^\circ\ 22' \\ \Omega &= 285\ 27 \\ i &= 126\ 49 \end{aligned}\right\}\ 1906{\cdot}0$$
$$q = 1{\cdot}2826$$

Ephemeris 12h. G.M.T.

1906	α (h. m.)		δ (° ′)		Brightness
Feb. 8	15 50·4	...	+70 37	...	1·04
,, 12	15 05·9	...	+78 37	...	1·05

Brightness at time of discovery = 1·0.

Thus it will be seen that the comet is now travelling due north, and is easily circumpolar, but it is in a better position for observations after midnight (Kiel *Circular*, No. 85).

A NEW METHOD OF DETERMINING THE MOON'S POSITION PHOTOGRAPHICALLY.—The chief difficulty in photographically recording the moon's position among the stars, for the purpose of determining the errors in the ephemeris, arises from the fact that if the exposures be long enough to record the faint, surrounding stars, the moon's image is tremendously over-exposed, and the star images are lost in the light-fog caused by the prevailing moonshine. Several methods of overcoming this difficulty have been proposed, and Mr. Wade, of the Helwan Observatory, Egypt, now suggests another, which, from his preliminary experiments, promises to be successful.

In this method the camera is mounted so that its optical axis passes horizontally through the centre of an ordinary cœlostat, but the mirror of the latter, instead of being worked to a true plane, is figured as a prism, the two faces of which are inclined at an angle of $7\frac{1}{2}^\circ$, and the edge of the prism is arranged parallel to the polar axis. Thus the photograph obtained includes two fields which are, actually, separated by 15° in right ascension.

The cœlostat is arranged so that one face of the prism reflects the moon's image into the camera, whilst the other face reflects the field of stars situated about 1 hour in right ascension from the moon, and therefore beyond the range of strong moonlight. Then the reflected lunar image is intercepted whilst the reflected star images are exposed for $2\frac{1}{2}$ minutes, when an instantaneous exposure on the moon is made. The operation is completed by exposing the star-field for a second $2\frac{1}{2}$ minutes. By this method Mr. Wade has obtained a number of successful negatives with a 2-inch visual achromatic Dallmeyer lens and a cœlostat of 4 inches diameter (*Monthly Notices Royal Astronomical Society*, vol. lxvi., No. 2).

A CATALOGUE OF SPECTROSCOPIC BINARIES.—A novel and important catalogue, published by the Lick Observatory as Bulletin No. 79, has just been received. It contains all the known particulars of the orbits of the spectroscopic binary stars discovered prior to January 1, 1905.

On that date 140 of these objects were known, 72 of them having been discovered by the Lick observers and 41 at the Yerkes Observatory.

When one remembers that the first of these interesting objects, ζ Ursæ Majoris, was discovered by Prof. Pickering so recently as 1889, it becomes evident that this field of research is likely to contain ample scope for further work; therefore in order to simplify matters for future observers Prof. Campbell and Dr. H. D. Curtis have collected all the known results into the present catalogue. In addition to the positions, magnitudes, spectral types, and orbital details of the binaries, the catalogue contains a valuable column in which the name of the discoverer and references to the bibliography of each binary, together with brief notes, are given.

OBSERVATIONS OF THE LYRID METEORS, APRIL, 1904.—In No. 4067 of the *Astronomische Nachrichten* Dr. Jiří Kaván, of the Prag-Smichow Astronomical Institute, gives the results of his observations of the Lyrids on April 18, 19, 20, and 21, 1904.

Forty-five meteors were observed, twenty of them being recorded between 12h. 5m. and 15h. 25m. (M.E.T.) on April 19. From an analysis of the records, Dr. Kaván has deduced two radiant points for this shower as follows:—

(1) $\alpha = 278^\circ{\cdot}0$ ... $\delta = +30^\circ{\cdot}5$ (near β Lyræ)
(2) $\alpha = 247{\cdot}0$ ... $\delta = +31{\cdot}5$ (near ζ Herculis).

REPORT OF THE MEETING OF THE SOLAR COMMISSION AT INNSBRUCK.

THE commission was constituted by the following action of the Southport meeting of the International Meteorological Committee thus reported:—

"Discussion of the relation of meteorology to astrophysics."

"The members of the Committee had previously taken part in a discussion of this subject at a meeting of Section A of the British Association; and Mr. Shaw proposed that a Commission should be appointed to review and discuss meteorological observations from the point of view of their connection with solar physics. Mr. Shaw's motion was adopted, and MM. Lockyer, Shaw, Pernter, and Angot were elected to serve on this Commission with power to add to their number and to elect their officers."

The following is the list of those who have been appointed members of this commission up to the present time:—

M. A. Angot, Bureau Central Météorologique, Paris.
Prof. H. J. Ångström, University, Upsala.
Geheimrat oberregierungs von Bezold, Berlin.
M. Teisserenc de Bort, Observatoire de Trappes, prés Paris.
Prof. F. H. Bigelow, Weather Bureau, Washington.
Prof. Birkeland, University of Christiania.
Rev. G. R. Cirera, S.J., Observatorio del Ebro, Tortosa, Spain.
Dr. W. G. Davis, Oficina Meteorologica Argentina, Cordoba, Argentine Republic.
M. H. Deslandres, Observatoire d'Astronomie physique, Meudon, Seine et Oise.
Sir John Eliot (secretary), 79 Alleyn Park, Dulwich, London; Bon Porto, Cavalaire, Var, France.
Mr. G. E. Hale, Solar Observatory, Mount Wilson, California, U.S.A.
Hofrat Prof. Dr. J. Hann, 19 Hohe Warte, Vienna, Austria.
M. M. S. Hepites, Institut Météorologique, Bucarest, Roumania.
M. Janssen, Observatoire d'Astronomie physique, Meudon, Seine et Oise.
Prof. W. H. Julius, Rijks Universiteit, Utrecht, Holland.
Hofrat. Prof. Dr. N. Thege v. Konkoly, k. meteor. Reichsanstalt, Budapest.
Prof. Dr. W. Köppen, Seewarte, Hamburg.
Mr. S. P. Langley, Secretary of the Smithsonian Institution, Washington, U.S.A.
Sir Norman Lockyer (president), Solar Physics Observatory, South Kensington, London.
Dr. W. J. S. Lockyer, Solar Physics Observatory, South Kensington, London.
Captain J. H. Lyons, R.E., Survey Department, Cairo, Egypt.
M. E. Marchand, Observatory, Pic du Midi.
Prof. H. Mohn, Meteorologische Institut, Christiania.
Hofrat. Prof. Dr. J. M. Pernter, Hohe Warte, Vienna, Austria.
Prof. Riccò, University of Catania, Sicily, Italy.
Prof. G. B. Rizzo, University of Messina, Sicily, Italy.
Mr. A. L. Rotch, Blue Hill Meteorological Observatory, Cambridge, Mass., U.S.A.
Sir Arthur Rücker, 19 Gledhow Gardens, London, S.W.

General Rykatcheff, St. Petersburg, Russia.
Prof. Dr. J. Scheiner, Konigl. Friedrich Wilhelms Universität, Berlin.
Dr. W. N. Shaw, Meteorological Office, 63 Victoria Street, London.
M. A. Silvado, Direction de Meteorologia, Morro de St. Antanis, Rio de Janeiro, Brazil.
Prof. A. Steen, Meteorological Institute, Christiania.
Mr. R. F. Stupart, Canadian Dominion Meteorological Service, Toronto.
Prof. J. Violle, Conservatoire des Arts et Métiers, Paris.
Prof. Dr. C. H. Wind, University of Utrecht, Holland.
Prof. A. Woeikoff, St. Petersburg, Russia.
Prof. Dr. Max Wolf, Grossherz Ruprecht-Karls Universität, Heidelberg, Germany.
Prof. A. Wölfer, Zurich Observatory, Switzerland.

At a meeting at Cambridge in August (18–23), 1904, Sir Norman Lockyer was elected president and Sir John Eliot secretary.

A provisional programme was considered, and the following resolutions were passed or action taken :—

A letter received from Mr. Hale respecting the cooperation of the Commission with the Committee on Solar Research of the National Academy of Sciences was read, and it was agreed to cooperate with the Committee on questions of common interest.

Upon the initiation of the Committee a union was formed for the study of solar phenomena, and Dr. W. J. S. Lockyer was appointed later by correspondence to attend the meeting of this union at Oxford in September, 1905, as the representative of the Commission.

A scheme of solar observations was approved.

It was resolved (1) that in connection with the observations of solar radiation, observations of the transparency of the air would be desirable, more especially (*a*) on the visibility of distant and high mountains when possible; and (*b*) photometrical observations of Polaris.

The following resolutions were passed :—

(1) That, in the first instance, for the purpose of comparison with solar phenomena, the meteorological observations to be considered should be monthly means of pressure, temperature (including maximum temperature and minimum temperature) and rainfall.

(2) That the members of the Commission be requested to communicate to the secretary a short report of the data available in their respective countries, and the number of years over which they extend.

(3) That a circular be addressed to the various meteorological organisations asking them to send to the secretary, for the purposes of the Commission, a copy of the publications of their offices embodying the data specified in the two preceding resolutions, and that the organisations be also requested to obtain and forward copies of similar publications from the colonies and dependencies of their respective countries.

(4) That the Commission considers it is desirable that the data for the purposes of comparison should be sent to the president of the Commission, South Kensington (Solar Physics Observatory), for tabulation and comparison. The Commission attaches the greatest importance to this work, more especially as it may lead to a practical system of long-period forecasting, and hopes that if it be necessary, an increase of staff at that observatory may be authorised to bring all old observations up to date.

(5) That the establishment of magnetical observatories in about lat. 70° N. (*e.g.* Bosskop, in Norway) and in very high latitudes of the southern hemisphere is of the highest importance for the advancement of science.

Prof. Riccò informed the Commission that it is intended to establish in Italy or Sicily a magnetic observatory with self-recording instruments belonging to the Italian Meteorological Office.

It was agreed that all communications for the Commission should be received at a central address, viz. the Solar Physics Observatory, South Kensington.

At the meeting at Innsbruck, September 11–15, 1905, the following resolutions were adopted :—

(1) That for the sake of brevity the name of the Commission be the Solar Commission of the International Meteorological Committee.

(2) That the secretary be instructed to report the proceedings of the meetings of the Commission held at Cambridge in August, 1904, and at Innsbruck in September, 1905, to the International Meteorological Committee, and to ask that it will take the proper steps to bring their suggestions before the International Association of Academies.

(3) Que pour la pression et la temperature les chefs des différents services météorologiques soient priés de preparer une liste des stations qu'ils considèrent comme suffisantes pour bien representer les différents régimes météorologiques que existent dans leur pays.

(4) Que dans le nord de Siberie et le nord de l'Amerique soient organizés des stations permanentes météorologiques au moins deux ou trois sur chaque continent.

La Commission exprime le desir de recevoir communication des observations des îles dont les noms suivent;[1] insiste sur l'utilité d'assurer la permanence des observations météorologiques dans ses regions, et prie son président de faire par intermédiaire du Comité international des Académies officiellement auprès des divers gouvernements les démarches necessaires pour que des observations météorologiques soient organizés et maintenues dans les stations mentionées ou ces observations n'existent pas d'une manière regulière et permanente.

A form was prepared and approved for the tabulation of the pressure, rainfall and temperature data.

Pour le but que poursuit la Commission, il est désirable que dans toutes les stations, les valeurs normales soient déduites des *mêmes* années (20, 25, ou plus) le millésime de la première année se terminant par 1 ou 6 d'après les recommendations du Congrès météorologique international de Vienne.

The normal period selected for comparison when possible is the twenty-five year period from 1881 to 1905.

M. Angot presented a selected list of stations for France which the Commission decided should be utilised in the circular as an example of the requirements of the Commission. In connection with this selection it was decided that the proportion of mountain stations to plain stations in any country should not exceed one to four.

The questions of magnetic and rainfall data were taken up, and it was resolved

(1) That the Magnetic Commission should be asked to assist the Solar Commission in the selection of magnetic observatories, and to advise as to the amount and extent of information which these observatories would be able to give in order to assist in the investigation of the relations of solar and terrestrial meteorology.

(2) That the suggestion of Mr. Langley that ten-day means as well as monthly means be employed be referred to the Magnetic Commission for opinion.

General Rykatcheff, president of the Magnetic Commission, read a communication in reply to the request mentioned above :—

" Décision de la Commission magnétique par rapport à la demande de la Commission solaire.

" La Commission magnétique a pris certaines décisions qui entrent dans les rues de la Commission solaire, celles sont les décisions sur la publication des courbes troublées, sur les listes des jours calmes et troublés, sur les coefficients exprimant l'activité magnétique de chaque jour et sur la publication d'une liste d'observatoires magnétiques.

La Commission magnétique décide que toutes ces publications seront communiquées aux membres de la Commission solaire.

" Si la Commission solaire trouverait que d'autres données, que celles enumerées tout à l'heure sont désirables, la Commission magnétique se déclare prête à collaborer avec la Commission solaire en la priant toutefois de vouloir bien presiser ses desirs !

" Quant à la question des moyennes par decades la Commission estime que cette question ne peut être resolu que par le comité des directeurs, auquel elle sera remise.

" La Commission magnétique estime qu'il serait bien de diriger l'attention du futur Bureau permanent magnétique sur les demandes de la Commission solaire."

(3) Pour le moment on se contente de demander les données relatives à la pluie aux stations que fournissent déjà celles de la temperature et de la pression; on pourra

[1] The complete list will be given later in the official report of the meeting of the Commission.

ultérieusement étendre le nombre des observations pluviométriques si la necessité s'en fait sentir.

(4) Les chefs des services météorologiques et hydrographiques sont priés d'ajouter aux données météorologiques envoyées à la Commission, autant de données sur la niveau et la debit des rivières et des lacs qu'ils croirent possibles et utiles.

(5) That the secretary be asked to prepare a regional statement of rainfall for India as an example of what the Commission desires in the way of reports of regional rainfall and variation of rainfall for each meteorological organisation.

Instructions were given to Dr. W. J. S. Lockyer for his action as representative of the Commission at the Oxford meeting of the Solar Research Union.

It was resolved that while thanking the Washington Weather Bureau for its courteous offer to publish in the Washington *Monthly Weather Review* the data collected by the Commission, the Commission is not yet in a position to decide upon the most appropriate form of publication.

It was decided that a circular should be sent to the various meteorological organisations in the following terms:—The Commission desire to direct attention to the concluding paragraph of Prof. Violle's report to the International Meteorological Committee, 1903, and would be greatly obliged if the Commission could be informed of the arrangements for observing solar radiation adopted at the observatories of the various meteorological organisations and the methods employed to render the observations comparable with those of other observatories.

A first list of places at which actinometric observations are made was presented.

It was resolved that "une circulaire sera envoyé aux directeurs des services météorologiques pour leur demander de designer les stations de leur pays ou les observations actinométriques sont regulièrement faites. Dans le liste des stations il serait utile d'éviter les grandes villes ou les conditions atmospheriques sont generalment défectueuses."

That steps should be taken to obtain observations from the places mentioned.

La Commission Solaire prie M. le Président de vouloir bien obtenir les courbes de la distribution de l'energie solaire pour les observatoires qui ont déjà l'obligéance de communiquer les autres données indiqués dans les Comptes rendus des Seances de la Conférence de Cambridge, à propos de la physique solaire.

ANTHROPOLOGICAL NOTES.

L'ANTHROPOLOGIE usually devotes much space to archæology, and the recent number (vol. xvi., Nos. 4–5) contains three papers on that subject. Mr. H. Obermaier gives the first instalment of a most useful memoir on Quaternary human remains and the sites in Central Europe where they have occurred. Mr. A. Viré describes a prehistoric cave of the Solutré period at Lacave (Lot); the human bones were too fragmentary to have any value. Mr. E. Cartailhac and Father Breuil continue their account of the mural paintings and engravings of the Pyrenean caves; they give several illustrations; as is usually the case among primitive peoples, the representations of human beings fall greatly below the excellence of animal delineations. The authors come to the conclusion that in the cave of Marsoulas the earlier engravings with linear contours are associated with black paintings, while the later engravings, in which the contours are made with short lines to indicate hair, are associated with polychromatic paintings of animals. In a paper on the myology of a Negro, Messrs. R. Anthony and A. Hazard state that muscles are thick and short, thus indicating strength rather than agility. Hunting and agriculture among the populations of the Sudan are the subjects of a paper by Mr. J. Decorse. Mr. L. G. Seurat describes the marae, or stone altars, of the little frequented eastern islands of the Tuamotu Archipelago. Mr. C. Monteil discourses on the numbers and numeration among the Mandés, a large linguistic family of people of western French Africa. The journal contains the usual valuable *résumé* of recent anthropological literature.

Two papers in the *Journal of the Asiatic Society of Bengal* (vol. lxxiii.) should not be overlooked. Mr. J. E. Friend-Pereira has discovered totemism among the Khonds, where the wider totemic exogamy has been hidden by the narrower and probably newer rule of the "local, communal, or family type." The "septs," as the author terms the totem groups, have the ordinary totem tabus of feeding, use and marriage, and myths of origin. He believes totemism "serves to mark to a primitive people who possess no written characters to record kinship and descent as they begin to get more remote in time the distinction between separate stocks of blood. In other words, totemism is merely a guide for the observance of the rules of exogamy: it is not the cause that originated or evolved these rules." He holds that the explanation of the origin of totemism must be sought for, not in its social, but in its religious aspect. Among the Khonds "the totem ranks as the spirit of the ancestor founder of the stock, who is also the chief tutelary deity of the stock, and the totem class is considered as a manifestation of the chief tutelary deity." Major P. R. T. Gurdon has a valuable short paper on the Khasis, Syntengs, and allied tribes of Assam, among whom mother-right so predominates that males can own only self-acquired property. There are traces of totemism. Ancestors are worshipped by the erection of remarkable memorial stones, of which two illustrations are given; this form of worship largely underlies the Khasi religious system. Divination by the breaking of eggs is very common. Major Gurdon is superintendent of ethnography in Assam, and is apparently preparing a monograph on the people under his charge which, judging from these notes, should be a valuable work.

The current number of the *Journal of the Anthropological Institute* (vol. xxxv., 1905) contains papers in all branches of anthropology. Physical anthropology is represented by a paper by Messrs. F. G. Parsons and C. R. Box on the relations of the cranial sutures to age, and by a critical paper by Dr. C. S. Myers traversing the conclusion of Miss Fawcett that in certain characters a progressive evolution has taken place in regard to the "prehistoric" and modern Egyptians. South African archæology has been much to the fore of late; the notes on the Great Zimbabwe elliptical ruin by Mr. Franklin White, and a paper on the stone forts and pits on the Inyanga Estate, Rhodesia, were written before Mr. Randall-MacIver's subversive views were published. Mr. T. W. Gann discourses on the ancient monuments of Honduras and on the natives now living there. In technology there is a beautifully illustrated paper by Mr. D. Randall-MacIver on the manufacture of pottery in Upper Egypt. Mr. N. W. Thomas enumerates the varieties of the canoes and rafts in Australia and their distribution. Mr. E. B. Haddon, in a well illustrated paper on the dog-motive in Bornean art, discusses the origin and degeneration of certain designs. Religion is represented by notes by Mr. R. E. Dennett on the philosophy of Bavili of Luango, West Africa. Finally, a report on the ethnology of the Stlatlumh, one of the Salish tribes of British Columbia, by Mr. C. Hill Tout, is a good example of a paper on regional ethnography. It will be seen that the journal maintains its high standard, both for the quality of its matter and the excellence of its illustrations.

A GAS CALORIMETER.

THE paper on a new gas calorimeter which was read before the Royal Society by Mr. C. V. Boys, F.R.S., on December 7, 1905, is of interest, partly on account of the causes which led to the design, and partly on account of the features which are original.

The agitation of the gas companies in favour of reducing the candle-power of gas on the ground that gas of lower candle-power is cheaper while the diminution of the light afforded by a luminous flame is of little consequence as incandescent lighting is so largely used, while it has succeeded in many cases in getting the statutory lighting power reduced, has on the other hand raised the question whether the value of the gas for heating purposes

and for power may not be reduced also, so that while the flame-lighting power may be reduced without much detriment, the consequent fall of heating-power may be a serious loss to the public. In the London Gas Act, 1905, such risk has been met by the obligation to test the calorific value of the gas for information only, but no penalties are incurred, even though the gas should prove to be of much less heating value than it has been.

The gas referees have therefore had the question of a suitable calorimeter before them, and in the "Notification" issued on January 1 (see p. 273) the calorimeter designed by Mr. Boys, who is one of them, is prescribed for use in official testings.

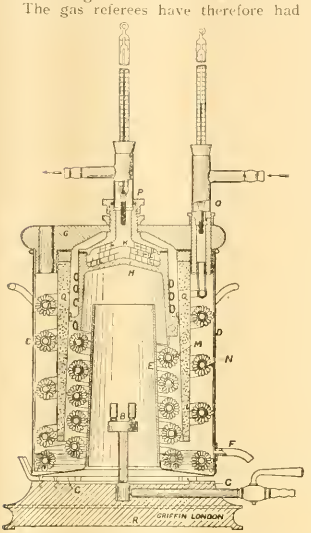

FIG. 1.

The calorimeter in question is of the Hartley type, *i.e.* a stream of water constantly passes through the instrument, and in so doing it is raised in temperature by the heat produced by the combustion of a stream of gas. The observations available enable the observer to ascertain the calorific value of the gas.

The best known instrument of this class is the Junker calorimeter, and it is in relation to this that the new features introduced by Mr. Boys are best described. From the accompanying figure it will be seen that the gas is burned at two small union jets instead of in the usual long Bunsen flame. The hot gases rising into the bell H descend outside the chimney E through the wires of the inner coil M. This and the outer coil N are made of the well known motor-car radiator tube invented by Mr. Clarkson. The circulating water enters the outer coil at the union O, and leaving the inner coil enters the space above the bell H, where it circulates between two dished plates and then leaves at the union P. The two lower turns of the Clarkson tube are immersed in a condensed water bath with an overflow F, which may be turned in any direction. This water bath serves to keep the chimney cool enough not to burn, but not cool enough to cause condensation to occur on the inner surface. One result of this construction is the slow passage of the products of combustion through the instrument and the small resistance they encounter. Hence the instrument need not be more than a foot high. The circulation of the water through the instrument strictly in series in every part prevents the formation of pockets or streaks of warmer water and consequent spasmodic changes of the outlet thermometer reading, and such small changes as might remain are almost entirely destroyed in the temperature equalising chamber above the bell H. The result is that, with a rise of temperature of 23° C., the variations do not exceed two or three hundredths of a degree, and even this appears to be largely due to friction in the meter insufficiently corrected by the governor.

Five minutes after lighting the gas the outlet thermometer is within 6 per cent. of its ultimate rise; in ten minutes it is within 2·2 per cent., and in fifteen minutes it is less than ½ per cent. In this and other respects the gas examiner who will have to use the instrument will find that not only accuracy, but his convenience has been studied.

One feature is quite peculiar. While hitherto gas calorimeters have been soldered up so as to be of the nature of mystery boxes, this can be seen in its essential features, while it can be completely taken to pieces in a few minutes for examination of every part.

After use the coil system is lifted out of the outer vessel by the lid and is then immersed in a dilute solution of bicarbonate of soda, so as to neutralise the weak sulphuric acid condensed upon the metal and prevent it and its dissolved oxygen from prematurely destroying the metal-work of the coils. The instrument is made by Messrs. Griffin and Sons.

THE ELECTRIC PRODUCTION OF NITRATES FROM THE ATMOSPHERE.[1]

As the demand of the white races for wheat as a foodstuff increases, the acreage devoted to wheat growing increases, but at a less rapid rate; and being limited by climatic conditions will in a few years, perhaps less than thirty, be entirely taken up. Then, as Sir William Crookes pointed out in his presidential address in 1898, there will be a wheat famine, unless the world's yield per acre (at present about 12·7 bushels per acre on the average) can be raised by use of fertilisers. Of such fertilisers the chief is nitrate of soda, exported from the nitre beds in Chili. The demand for this has risen from 1,000,000 tons in 1892 to 1,543,120 tons in 1905, and the supply will at the present rate be exhausted in less than fifty years. Then the only chance of averting starvation lies, as Crookes pointed out, through the laboratory.

In 1781, Cavendish had observed that nitrogen, which exists in illimitable quantities in the air, can be caused to enter into combination with oxygen, and later he showed that nitrous fumes could be produced by passing electric sparks through air. Although this laboratory experiment had undoubtedly pointed the way, though the chemistry of the arc flame had been investigated in 1880 by Dewar, and though Crookes and Lord Rayleigh had both employed electric discharges to cause nitrogen and oxygen to enter into combination, no commercial process had been found practical for the synthesis of nitrates from the air until recently.

After referring, in passing, to the tentative processes of Bradley and Lovejoy, of Kowalski, of Naville, and to the cyanamide and cyanide processes, attention was directed to the process of Birkeland and Eyde, of Christiania, for the fixation of atmospheric nitrogen, and their synthetic production of nitrates, by use of a special electric furnace. In this furnace an alternating electric arc was produced at between 3000 and 4000 volts, but under special conditions which resulted from the researches of Prof. Birkeland, the arc being formed between the poles of a large electromagnet, which forced it to take the form of a roaring disc of flame. Such a disc of flame was shown in the lecture theatre by a model apparatus sent from Christiania. In the furnaces, as used in Norway, the disc of flame was 4 feet or 5 feet in diameter, and was enclosed in a metal envelope lined with firebrick. Through this furnace air was blown, and emerged charged with nitric oxide fumes. These fumes were collected, allowed time further to oxidise, then absorbed in water-towers or in quicklime, nitric acid and nitrate of lime being the products. The research station near Arendal was described, also the factory at Notodden, in the Hitterdal, where electric power to the extent of 1500 kilowatts was already taken from the Tinnfoss waterfall for the production of nitrate of lime. This product in several forms, including a basic nitrate, was known as Norwegian saltpetre. Experiment had shown that it was equally good as a fertiliser with Chili saltpetre, and the lime in it was of special advantage for certain soils. The yield of product in these furnaces was most satisfactory, and the factory at Notodden—which had been in commercial operation since the spring of 1905—was about to be enlarged; the neighbouring waterfall of

[1] Abstract of a discourse delivered at the Royal Institution on Friday, February 2, by Prof. Silvanus P. Thompson, F.R.S.

Svaelgfos being now in course of utilisation would furnish 23,000 horse-power. The Norwegian company had further projects in hand for the utilisation of three other waterfalls, including the Rjukanfos, the most considerable fall in Telemarken, which would yield more than 200,000 horse-power. According to the statement of Prof. Otto Witt, the yield of the Birkeland-Eyde furnaces was more than 500 kilograms of nitric acid per year for every kilowatt of power. The conditions in Norway were exceptionally good for the furnishing of power at exceedingly low rates. Hence the new product could compete with Chili saltpetre on the market, and would become every year more valuable as the demand for nitrates increased, and the natural supplies became exhausted.

POLAR EXPLORATION.

After discussion at a meeting of explorers and geographers interested in the study of the polar regions, a statement was submitted to the congress held at Mons in September, 1905, setting forth the expediency of founding an International Association for the Study of the Polar Regions, with the objects of "(1) obtaining an international agreement upon different questions associated with polar geography; (2) making a general effort to reach the terrestrial poles; (3) organising expeditions having for their object an extension of our knowledge of the polar regions in every respect; and (4) forming a programme of scientific work to be carried out in the different countries during the existence of the International Polar Expeditions." The congress unanimously passed a resolution expressing the wish "(1) to see the formation of this Association in 1906 by a previous meeting of a general Conference of the larger scientific and maritime nations, who have taken part in the principal polar expeditions up to the present time; and (2) to see that the Belgian Government takes the initiative in approaching the Governments of other countries."

We have received a copy of a letter which has been addressed by M. Lecointe, to whom the congress entrusted the work of making the necessary preliminary arrangements, to the presidents of academies and of learned societies all over the world. It is proposed to hold the first conference at the beginning of May, for the consideration of general questions, and to discuss in detail "(1) the basis of a series of polar expeditions; (2) the programme of term of observations to be carried out in all the observatories; and (3) the text of the working arrangements of the International Association" at a second conference, composed of State delegates and delegates from academies and learned societies, in September. The conclusions arrived at by the second conference will be transmitted for examination to the Belgian Government, which eventually will ask the support of other countries for the new association.

In connection with the proposed International Association for the Study of the Polar Regions, M. Lecointe invites polar explorers to send him papers or notices dealing with questions which will be considered at the general conference in May next. A paper of the kind has been issued in which M. Henryk Arctowski makes a number of suggestions for work in the future. M. Arctowski expresses the opinion that in future Arctic research much use may be made of ice-breakers of the type of Makaroff's *Yermak*. With regard to Antarctic exploration, the settlement of the continental question is admittedly of primary importance, but M. Arctowski strongly urges the advisability of exploring thoroughly the circumpolar areas as a preliminary, especially by hydrographical expeditions.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The recommendation of the Forestry Syndicate with regard to the general management of the examinations, the schedules of the proposed forestry examination, &c., passed the Senate last Thursday. The most important of these recommendations is that the general conduct of the examinations and the prescription of courses of training are to be entrusted to a committee of the Board of Agricultural Studies. Such a committee will include the professors of agriculture, botany, chemistry, and geology, and the reader in agricultural chemistry, together with three other members of the Board of Agricultural Studies. The committee will have the power to co-opt annually, if it thinks fit, four other persons.

The professor of experimental physics gives notice that a course of three lectures on "The Life-history of Surface Air Currents" will be given by Dr. W. N. Shaw, F.R.S., director of the Meteorological Office, in the Cavendish Laboratory on Wednesdays, February 14 and February 21, and Thursday, March 1.

London.—Prof. E. A. Minchin commenced at University College on Monday a course of lectures on "Parasitic Protozoa." Prof. Minchin recently returned from Uganda, where he was engaged as one of the special commissioners of the Tropical Diseases Committee of the Royal Society in research on the life-history of the trypanosome of sleeping sickness.

Prof. Drude has been elected rector of the Dresden Technical High School for the ensuing year.

During January, Dr. Bolam, lecturer on chemistry at Queen Margaret College, Glasgow University, delivered in Leith Nautical College a short course of lectures on "The Chemistry of Dangerous Cargoes" to large nautical audiences. Mr. James Currie (of Messrs. James Currie and Co.) presided, and pointed out the importance of the course in view of the very complex cargoes merchant ships were now carrying.

Mr. H. F. Trippel directs attention to an important point in connection with army entrance examinations in a letter to the *Pall Mall Gazette* of February 3. Mathematics is a compulsory subject for every candidate competing for admission to the Royal Military Academy, Woolwich; yet Mr. Trippel says that in the recent examination one of the competitors who scored zero in mathematics was placed among the successful candidates. It appears, therefore, that though it is compulsory to take mathematics in the competitive examination, a candidate may do so without having any serious intention of gaining a single mark in the subject. Now that the attention of the authorities has been directed to the defect in the regulations which permits this course to be followed, it is to be hoped that a minimum standard of marks to be gained in mathematics by all candidates will be prescribed, or some other remedy found.

SOCIETIES AND ACADEMIES.

London.

Geological Society, January 10.—Dr. J. E. Marr, F.R.S., president, in the chair.—The clay-with-flints: its origin and distribution: A. J. **Jukes-Browne.** Until recently the clay-with-flints has been regarded as being, in the main, a residue from the slow solution of the Chalk. Of late years, the opinion has been growing that it consists very largely of material derived from the Eocene. The present paper is devoted to an examination of the facts, with the view of ascertaining whether the clay-with-flints could possibly be derived from the Chalk, or whether the theory of its derivation from the Eocene is confirmed by more detailed inquiry. From several lines of investigation the author concludes (1) that the clay-with-flints cannot have been formed from mere solution of the Upper Chalk; (2) that all its components, except the unbroken and angular flints, could have been furnished by the Reading beds; (3) that the positions occupied by it are such that no great thickness of Chalk can have been destroyed to form it, the tracts being seldom more than 30 feet or 40 feet below the local plane of the Eocene base, or the presumed level of that plane.—Footprints from the Permian of Mansfield (Nottinghamshire): G. **Hickling.** These fossils were discovered in 1897 by Mr. Francis Holmes in the Rock Valley Quarry, Mansfield, in a local, lenticular mass of sandstone intercalated in the Magnesian Limestone. The prints present some resemblance to those named *Ichnium acrodactylum*, from the Upper Permian of Thuringia.

Zoological Society, January 16.—Mr. Howard Saunders, vice-president, in the chair.—Some bones of the lynx (*Felix lynx*) found in a limestone cavern in Cales Dale, Derbyshire: W. Storrs **Fox**. This was only the third record of remains of this species having been met with in the British Islands.—Mammals recently collected in the Malay Peninsula by Mr. C. B. Kloss, and presented to the National Museum: J. L. **Bonhote**. The collection contained examples of seventeen species, chiefly rodents, of which two, representing well known Bornean species, were described as new. There was also a series of *Mus jarak*, a species hitherto known from one specimen only, and recently described by the author.—The minute structure of the teeth of the creodonts: C. S. **Tomes**. The author stated that suggestions which had been made as to a possible relationship between the creodonts and the polyprotodont marsupials had rendered it interesting to see how far the structure of their teeth either supported or tended to disprove such speculations. Marsupial teeth possessed in the structure of their enamel a well marked peculiarity, namely, the free penetration of the epiblastic enamel by tubes continuous with those of the mesoblastic dentine, and it happened that recent Carnivora, the descendants, more or less direct, of the creodonts, also presented a disposition of the prisms of their enamel somewhat unusual amongst Mammalia. Teeth of Hyænodon, Sinopa, Oxyæna, Pachyæna, Borhyæna, Didynictis, and Cynodictis had been examined, and in none of them were marsupial characters observed; on the contrary, in most of them characteristic carnivorous patterns were found, so that in Oligocene and Eocene times their enamel had already attained to its full specialisations.—Contributions to the anatomy of the Ophidia: F. E. **Beddard**.—Synopsis of the toads of the genus Nectophryne, with special remarks on some known species and description of a new species from German East Africa: Dr. J. **Roux**.

Royal Meteorological Society, January 17.—Mr. Richard Bentley, president, in the chair.—Annual general meeting.—Address on meteorology in daily life: R. **Bentley**. The president referred to the increasing interest shown lately throughout the country in the study of meteorology, and to the recent advances which had been made in it—more especially in the analysis of the composition of the atmosphere—and in the investigation of the upper currents of the air. He also laid stress on the increasing urgency of safeguarding the water supply, and gave various illustrations of the effects of weather on human life, on the land, on navigation, on transit, &c.

Royal Microscopical Society, January 17.—Dr. D. H. Scott, F.R.S., president, in the chair, annual meeting.—Annual address, the subject being "The Life and Work of Bernard Renault": **President**.

Chemical Society, January 18.—Prof. R. Meldola, F.R.S., president, in the chair.—The refractive indices of crystallising solutions, with especial reference to the passage from the metastable to the labile condition: H. A. **Miers** and F. **Isaac**. The authors found that the refractive index of a strong solution of sodium nitrate, measured at intervals while the liquid cools, rises to a maximum value and then falls, crystals appearing before the maximum is reached. There are always two periods of crystallisation: a first, in which a few crystals are growing gradually; a second, in which many crystals appear spontaneously. The authors regard these as being undoubtedly the metastable and labile states.—The effect of constitution on the rotatory power of optically active nitrogen compounds, part i.: M. B. **Thomas** and H. O. **Jones**. The resolution of a set of optically active nitrogen compounds and the examination of the rotatory power of their salts in dilute aqueous solution have been made in order to find the rotatory power of the ions. The values of $[M]_D$ for some of the principal alkyl radicals are given.—The determination of available plant food in soil by the use of weak acid solvents: A. D. **Hall** and A. **Amos**. The authors have investigated the effect of repeating the attack of weak acid solvents on soils of known history derived from the Rothamsted experimental plots. In the case of soils continuously manured with superphosphate, the phosphoric acid goes into solution at a rate which decreases logarithmically, but soils which have received complex manures do not show the same regular decrement in the amounts of phosphoric acid passing into solution.—The action of ammonia and amines on diazo-benzene picrate: O. **Silberrad** and G. **Rotter**.—The preparation of bistriazobenzene: O. **Silberrad** and B. J. **Smart**.—Gradual decomposition of ethyl diazoacetate: O. **Silberrad** and C. S. **Roy**.—Studies on nitrogen iodide, iii., the action of methyl and benzyl iodides: O. **Silberrad** and B. J. **Smart**.—Action of bromine on benzeneazo-*o*-nitrophenol: J. T. **Hewitt** and N. **Walker**.—The condensation of dimethyldihydroresorcin and of chloroketodimethyltetrahydrobenzene with primary amines, part i., monamines, ammonia, aniline, and *p*-toluidine: P. **Haas**.—Silicon researches, part x., silicon thiocyanate: J. E. **Reynolds**. The author found that silicon thiocyanate, $Si(SCN)_4$, is best prepared by prolonged digestion of excess of pure lead thiocyanate in a benzene solution of silicon tetrachloride.—Halogen derivatives of substituted oxamides: F. D. **Chattaway** and W. H. **Lewis**. A number of substances obtained by the action of halogens on substituted oxamides are described.—Menthyl benzene-sulphonate and menthyl naphthalene-β-sulphonate: T. S. **Patterson** and J. **Frew**.—Some reactions and new compounds of fluorine: E. B. R. **Prideaux**. The fluorine prepared by the electrolysis of anhydrous hydrogen fluoride, contained in a copper vessel, was found to contain oxygen produced at the anode even after the current had passed for a considerable time. Liquid fluorine has no solvent or chemical action on iodine or solid bromine. Bromine fluoride, BrF_3, was prepared for the first time. Gaseous fluorides of selenium, SeF_6, and tellurium, TeF_6, were prepared by direct combination. The vapour pressure curve of SF_6 was compared with those of SeF_6 and TeF_6, and shown to be similar.—Contributions to the chemistry of the rare earths, part i.: M. **Esposito**. The various methods advocated by Watts, Brauner, Popps, Mosander, Debray and others for the separation of cerium, lanthanum, and "old didymium" have been examined comparatively.—A synthesis of aldehydes by Grignard's reaction: G. W. **Monier-Williams**.—The action of ultraviolet light on moist and dry carbon dioxide: S. **Chadwick**, J. E. **Ramsbottom**, and D. L. **Chapman**.—A contribution to the study of stable diazo-compounds, preliminary note: G. T. **Morgan** and W. O. **Wootton**.—Triarylsulphonium bases: S. **Smiles** and R. **Le Rossignol**.—An improved apparatus for the continuous extraction of liquids with ether: R. S. **Bowman**. In this apparatus, which comprises a simple system of tubes, a condenser, and two ordinary flasks, the extraction is effected by passing cool liquid ether through the solution.

Physical Society, January 26.—Prof. J. H. Poynting, F.R.S., president, in the chair.—The isothermal distillation of nitrogen and oxygen and of argon and oxygen: J. K. **Inglis**. Mixtures of liquid nitrogen and oxygen are particularly suitable for an exact study of the relations obtaining during isothermal distillation, for the distillation bulb being the coldest instead of the hottest part of the apparatus, errors due to back condensation, &c., can be eliminated. In addition, the vapour can easily be circulated and passed time after time through the liquid until equilibrium is complete. Experiments were carried out in this way in a specially designed apparatus, and the results showed that the ratio of nitrogen to oxygen in the vapour was not in a constant proportion to the same ratio in the liquid. When, however, the partial pressures of nitrogen and oxygen were plotted against the *concentrations* in the liquid a straight line was obtained in the case of nitrogen and a curve in the case of oxygen. This indicated that nitrogen obeyed Henry's law of solubility, and the deviation in the case of oxygen pointed to its being slightly associated in the liquid state when mixed with nitrogen. A few experiments were also carried out with mixtures of argon and oxygen. At the temperature used, argon was a volatile solid, and therefore the greatest concentration of argon that could be obtained was that of the saturated solution in oxygen. Argon seemed to agree with nitrogen in obeying Henry's law.—The use of chilled cast iron for permanent magnets: A. **Campbell**. The present investigation was made on rings in addition to rods of the standard dimensions usual in testing magnet-steels. All

the specimens were heated to 1000° C. and then chilled in cold water, care being taken to support them during the process, as cast-iron is very brittle at such a high temperature. The rods were tested for maximum remanent B and coërcivity by Madame Curie's method, the magnetised bar being placed in a long solenoid producing a demagnetising field which was gradually increased until a search-coil slipped along the bar showed that the demagnetisation was complete. The results showed the chilled cast-iron to be not very inferior to ordinary magnet-steel. By ballistic tests on the two rings, their permeability curves were obtained, and these indicated that the simple process of chilling used was quite satisfactory even for a tolerably massive ring of 6 sq. cm. cross section. The cheapness and ease of working cast-iron should encourage instrument makers to test its capabilities in various instruments.—Experiments on the propagation of longitudinal waves of magnetic flux along iron wires and rods: Prof. **Lyle** and Mr. **Baldwin.** The experiments described in the paper were undertaken with the object of determining if there is a definite rate of propagation of magnetism in iron. The method adopted was to produce magnetisation at a particular point on a bar by means of a coil through which an alternating current was passed, and then to observe the magnetic flux at various distances from the coil by means of a small secondary coil, free to be moved to various places on the bar. By the use of Prof. Lyle's wave-tracer the magnetic flux at various points along the bar was thus obtainable. The wave curve was then analysed by Fourier's series. Various curves given in the paper show the value of the constants in Fourier's series and of the lag in the magnetisation as the coil was moved along the bar. Contrary to what had been observed in previous researches, the authors found that the phase lag, instead of continuously increasing along the bar, reached a maximum value and then diminished, proving the absence of true wave propagation.

Mineralogical Society, January 23.—Prof. H. A. Miers, F.R.S., president, in the chair.—Studies in crystallisation; sodium nitrate: H. A. **Miers** and J. **Chevalier.** Microscopic observations were made upon solutions of known strength contained in open tubes or sealed tubes maintained at a known temperature, or in the form of drops upon a slide, with the object of comparing the growth of crystals in metastable and labile solutions respectively. The limits of the labile state (in which the solution can crystallise spontaneously) have been fixed by previous experiments by H. A. Miers and Miss F. Isaac. If a crystal of the salt be introduced into a supersaturated solution which is not labile, the centres of growth of new crystals are on its surface, and they grow in parallel positions upon it; if it be introduced into a labile solution the new centres of growth are in its neighbourhood, and the crystals fall upon it in various positions. If it be moved about in either, a cloud of crystals is produced; but in the metastable solution this appears to be due to minute crystals which are swept from its surface. A crystal having appeared spontaneously can continue to grow in a labile solution without producing others in its neighbourhood, but if introduced it at once produces a cloud. This may be because the growing crystal is surrounded by a zone of metastable solution.—Geikielite and the ferro-magnesian titanates: T. **Crook** and B. M. **Jones.** Geikielite occurs in association with magnesian menaccanite and common ilmenite (menaccanite) in the gem gravels of the Balangoda and Rakwana districts of Ceylon. A considerable number of analyses indicate that geikielite varies in composition, the iron oxides ranging from 8 per cent. to 14 per cent. No specimen has hitherto been found which contains less than 8·1 per cent. of iron oxide. For this reason the formula $(Mg,Fe)TiO_3$ is preferable to $MgTiO_3$ as expressing the true composition of geikielite. Magnesian menaccanite containing about 28 per cent. of iron oxide is very closely allied to geikielite in all its properties, more so than to common ilmenite. The alteration products of geikielite are similar to those of ilmenite, consisting of rutile and so-called leucoxene; the latter is a mixture of amorphous titanic acid, sphene, and limonite. It seems advisable to classify the ferro-magnesian titanates as ilmenites and geikielites, treating magnesian menaccanite (which has the formula $(Fe,Mg)TiO_3$, where $Fe : Mg = 1 : 1$) as the middle member of the series.—G. F. Herbert **Smith** exhibited, and explained the use of, a diagram for the graphical determination of the refractive index from the prism angle and the angle of minimum deviation. He also explained a simple test for ascertaining the pair of faces corresponding to any refracted image.

Dublin.

Royal Dublin Society, December 19, 1905.—Dr. R. F. Scharff in the chair.—The causes of "blowing" in tins of condensed milk: Dr. G. H. **Pethybridge.** Blowing (*i.e.* bulging) is caused by the accumulation of gas produced by the fermentation of the cane sugar added during manufacture by certain wild yeasts or torulæ, which can ferment saturated solutions of sugar, and appear to be present in the original milk supplies, and are not introduced during the process of manufacture.—Two new species of Collembola for Ireland: Prof. G. H. **Carpenter.** The species described belong to the genera Isotoma and Entomobrya, the latter showing some interesting special affinities with Orchesella.

Edinburgh.

Royal Society, January 8.—Prof. Crum Brown, vice-president, in the chair.—*Bathydraco Scotiae*, Poisson abyssal nouveau recueilli par l'Expedition Antarctique national Écossaise. Note préliminaire: Louis **Dollo.** The genus Bathydraco was instituted by Günther in 1878 for a small fish (*B. antarcticus*, Günth.) from the south east of Heard Island, inhabiting a depth of 1260 fathoms. The new species, named by M. Dollo, was obtained in the Weddell Sea at a depth of 1410 fathoms.—Influence of thymus feeding on allantoin excretion: Dr. J. **Maclachlan.** The work was based on experiments carried out in the laboratory of the Royal College of Physicians of Edinburgh. Reference was made to the very unsatisfactory nature of the evidence on the influence of uric acid and nucleins on the production of allantoin, and it was pointed out that the administration of thymus substance was invariably followed by a large production of allantoin. The point investigated was whether this was due to the conversion of the nucleins and puric bodies contained in the thymus or to some specific action of the substance. Boiling the thymus before it was administered reduced its power of producing allantoin to less than half. Thymus also was found to exercise a much more marked effect in causing the production of allantoin than other glands, such as pancreas, liver, and lymphatic glands, which are also rich in nucleins. The conclusion drawn was that raw thymus when administered produced a specific action on the metabolism by which the formation of allantoin was increased.—A theorem in hyper-complex numbers: J. H. Maclagan **Wedderburn.** A short proof was given of a theorem, first proved by Scheffers, that an algebra which contains the quaternion algebra can, if the moduli of the two algebras are the same, be expressed as the product of the quaternion algebra and another algebra. The theorem was then extended to a large and important class of algebras.

January 22.—Lord M'Laren, vice-president, in the chair.—A form of initiational disturbance more convenient than that of §§ 3–31 of previous papers on waves: Lord **Kelvin.** The investigations of §§ 5–31, including the "front and rear" of infinitely long free processions of waves in deep water, are all founded on superposition of equidistant initiational disturbances, the first of two typical forms described in §§ 3, 4. In this form the initial disturbance is everywhere elevation or everywhere depression, and its amount at great distances from the middle varies inversely as the square root of the distance from a horizontal line at a small height above the water surface in the middle of the disturbance. A type-disturbance derived mathematically from that used in §§ 5–31 by double differentiation with reference to time, or by single differentiation of the second of the forms of §§ 3, 4 with reference to space, is given in the present paper, and illustrated by diagrams of curves placed before the society, in which the initial disturbance has as much water above as below the undisturbed level; and at great distances the depression or elevation varies inversely as the 3/2 power

of the distance. This derived solution is used in the two following papers, for which it is found much more convenient than the solution used in §§ 5–31.—Illustrations of the indefinite extension and multiplication of a group of two-dimensional deep-sea waves, initially finite: Lord **Kelvin.** The water is left at rest and free, after being artificially displaced to a configuration of a finite number of sinusoidal mountains and valleys—five mountains and four valleys in the initiation of the diagrams placed before the society. Immediately after the water is left free, the disturbance begins analysing itself into two groups of waves, seen travelling in contrary directions from the middle line of the diagram. The perceptible fronts of these two groups extend rightwards and leftwards from the end of the initial single static group, far beyond the "hypothetical fronts" supposed to travel at half the wave velocity, which (according to the dynamics of Osborne Reynolds and Rayleigh in their important and interesting consideration of the work required to feed a uniform procession of water-waves) would be the actual fronts if the free groups remained uniform. How far this is from being the truth is illustrated by the diagrams. Besides the great extension of the fronts outward from the middle, we see that the two groups, after emergence from perceptible co-existence in the middle, travel with their rears leaving a widening space between them of water not perceptibly disturbed, and with wavelets in ever augmenting number following slower and slower in the rear of each group and causing the extreme perceptible rear to travel at a much smaller speed than half the "wave velocity." It is obviously difficult to give any definition of an "effective front," or of a "centre of group," or of a "virtual rear," according to which we could regard the group as travelling with half the wave velocity or *with any single definite velocity*.—The initiation and continued growth of a train of two-dimensional waves due to the sudden commencement of a stationary periodically varying forcive: Lord **Kelvin.** A forcive consisting of a finite sinusoidally varying pressure is applied, and kept through all time applied, to the surface of the water within a finite practically limited space on each side of the middle line of the disturbance. In the beginning the water was everywhere at rest and its surface horizontal. The problem to be solved is, to find the elevation or depression of the water at any distance from the mid-line of the working forcive, and at any time after the forcive began to act. The solution was illustrated by two diagrams—time curves—one showing the motion of the water at the mid-line of the working forcive, the other showing the motion at a distance from this line equal to the wave-length that would be in an endless uniform procession of waves having period equal to the period of the disturbing forcive. Calculations are in progress to give the motion of the water at eight wave-lengths from the source. The detailed calculations were made and the curves drawn for Lord Kelvin by Mr. George Green.

Erratum.—In the report of the meeting of November 20, 1905 (NATURE, December 28, 1905), the words "quite did away with" on p. 216, line 23, should be "had no appreciable effect on."

PARIS.

Academy of Sciences, January 29.—M. H. Poincaré in the chair.—New researches on the insoluble alkaline compounds contained in living plants: M. **Berthelot.**—The capture of a whale (genus Kogia) near Roscoff, English Channel: Yves **Delage.** The animal was captured at Siec, about 6 kilometres from Roscoff. The species is extremely rare, and has never been previously observed in European waters.—Certain systems of circles and spheres which occur in the deformation of quadrics: C. **Guichard.**—The perpetual secretary announced the death of Sir John Burdon-Sanderson, correspondant for the section of medicine and surgery.—Differential equations of the second order of which the general integral is uniform: M. **Gambier.**—The flame spectrum of mercury: C. **de Watteville.** Attempts to photograph a flame spectrum of mercury have been hitherto unsuccessful. By the use of solutions of the acetate and cyanide of mercury, sprayed into a flame, the author has been successful in obtaining the flame spectrum of mercury, consisting of the single line 2536·72. This line was measured by Kayser and Runge in the arc spectrum of mercury.—The duration of the discharge in an X-ray tube: André **Broca.** With equivalent sparking distances varying from 6 cm. to 10 cm., the time was practically constant, 0·0006 sec.—The diminution of the radio-activity of polonium with time: Mme. **Curie.** The intensity of the radiation diminishes with the time according to a simple exponential law, $I = I_0 e^{-at}$. If t is expressed in days, $a = 0{\cdot}00495$, or the intensity falls to half its value in 140 days. A diagram is given showing the linear relation between log I and the time, the deviations between the values obtained from the above law and from experiment not exceeding 3 per cent. The agreement of the constant (0·00495) with that found by Marckwald for radiotellurium (0·00497) shows that the latter substance is identical with polonium.—The sulphates of some rare metals: Camille **Matignon.** Thermochemical measurements on the sulphates of lanthanum, praseodymium, neodymium, and samarium.—The rapid preparation of solutions of hydriodic acid: F. **Bodroux.** A given weight of iodine is divided into two equal portions. By the interaction of barium peroxide and the first portion, barium iodide is produced; the remainder of the iodine is dissolved in the solution of barium iodide, and the liquid treated with sulphur dioxide until decolorised, filtered from the barium sulphate, and redistilled.—An alloy of thorium and aluminium: O. **Hönigschmid.** This alloy, the composition of which corresponds to the formula $ThAl_3$, can be obtained in the form of long hexagonal prismatic needles possessing the colour and metallic lustre of aluminium, by the reduction of thorium oxide by aluminium in the electric furnace. It can also be obtained by the interaction of aluminium and the double fluoride of aluminium and thorium at a high temperature.—Researches on the halogen compounds of the borates of barium and strontium: L. **Ouvrard.** The borates of barium and strontium appear to enter into combination with chlorine and bromine less easily than the corresponding salts of calcium, only one halogen compound of each being obtainable.—α- and β-campholytic alcohols: G. **Blanc.** Details of preparation and physical properties. The pyruvic ester of each is described, and the corresponding semicarbazones.—The influence of the reaction of the medium upon the activity of the diastases: A. **Fernbach.** Remarks on a recent note on the same subject by L. Maquenne and E. Roux.—The nutrition of green plants by amides in the absence of carbon dioxide: Jules **Lefèvre.** Experiments made on the dwarf nasturtium led to the following conclusions:—Plants deprived of carbon dioxide and amides lose a notable proportion of their initial weight, this loss being due to respiration. Plants kept in the light, with amides present in the soil, in spite of the absence of carbon dioxide, developed and increased their dry weight. Light is essential for the utilisation of the amides by the plant.—A new parasitic fungus, *Trematovalsa Matruchoti*, causing the disease of the silver lime tree: Nicolas **Jacobesco.** This fungus is the cause of a disease which has ravaged the lime forests of Wallachia. It appears to belong to a new family.—The classification into genera of the family of the Bradypodidæ (genus Hemibradypus): R. **Anthony.**—Contribution to the general morphology of the higher Protozoa: J. **Kunstler** and Ch. **Gineste.**—The anatomy and histology of the Ixodidæ: A. **Bonnet.**—The effect of the injection of extract of the interstitial gland of the testicle on the growth: P. **Ancel** and P. **Bouin.**—Tables of growth drawn up in 1905 from the measurements of 4400 Parisian children between the ages of one and fifteen years: MM. **Variot** and **Chaumet.** The results are given both in graphical and tabular form, comparison being made with similar measurements of Bowditch (Massachusetts) and Rotch (Boston).—The physiological conditions of oral teaching: Pierre **Bonnier.** The effects of a want of knowledge of the principles of voice production are throat troubles with the teachers and increased mental effort on the part of the pupils. Measurements are given showing the importance of the latter effect.—Chloroform anæsthesia. The estimation of the chloroform before, during, and after anæsthesia is set up, and the quantity in the blood at the moment of death: Maurice **Nicloux.**—The Neocretacean ammonites collected by the Swedish Antarctic Expedition: W. **Kilian.**—The geology of the Peloponnesus: Ph. **Négris.**

GOTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), parts iv. and v. for 1905, contains the following memoirs communicated to the society :—

July 8.—Determination of all curves by the translation of which minimal surfaces are generated : P. **Stäckel.**

July 22.—Outlines of a general theory of linear integral equations, x., Riemann's problems in the theory of functions of a complex variable : D. **Hilbert.**—On finite algebras : L. E. **Dickson.**—On pyroelectricity in centro-symmetric crystals ; with appendix (October 28) : On the piezoelectricity of centric crystals : W. **Voigt.**

August 5.—On the origin of the salt deposits of north-west Germany : A. **von Koenen.**

November 25.—Remarks on an essay on the stellate appearance of the stars (*Nachrichten*, 1905, p. 238). The effect of the background on the estimation of magnitude (*e.g.* of the moon on the horizon). BIOLOGICAL HERESIES.

The Nature and Origin of Living Matter. By Dr. H. Charlton Bastian, F.R.S. Pp. 344; with 245 illustrations from photomicrographs. (London: T. Fisher Unwin, 1905.) Price 12*s.* 6*d.* net.

DR. H. CHARLTON BASTIAN re-expounds his well known biological heresies with a vigour and industry worthy of a better cause. The first heresy is that "*archebiosis*" is a present occurrence, that is, that living organisms may here and now arise from non-living materials. What seems to most biologists so difficult to conceive with any concreteness, that their evolutionist faith is strained a little to believe it may have occurred *once* long ago, may be seen occurring any day in this veteran experimenter's laboratory. What Pasteur looked out for in vain for a score of years has been revealed to Bastian's persistent patience. The second heresy is that "*heterogenesis*" is not infrequent, that is, that a living creature may give rise to alien offspring, to organisms quite different from itself, it may be belonging to a different class altogether. Against the fact of the persistence or continuity of hereditary resemblance we are accustomed to balance the fact of variation; but now we are asked to make room for what is more than the most convinced believer in mutations or transilience ever dreamed of, namely, such facts of heterogenesis as the production of infusorians from a rotifer's egg. Our convictions as to the specific plasmic architecture of different forms of life, our difficulty in imagining how chlorophyll corpuscles can become a swarm of sun-animalcules, must be corrected, like other prejudices, by facing the facts. To ignore these is the worst form of *ignorantia elenchi* of which scientific students can be guilty. If nature's method includes the hop, step, and leap phenomena, which this book describes at great length, what can excuse the blindness of those who persist that evolution is like a snail's continuous crawl?

To see what Dr. Bastian interprets as archebiosis, we are recommended to take an infusion of turnip or fresh beef, to filter this through two layers of the finest Swedish paper, to let a drop fall on a cleaned microscope slip, to put a cover-glass on, to remove excess of fluid with blotting-paper, to allow one or more air-bubbles to remain in the film, to seal up with melted paraffin wax, to fix upon a clear space free from particles near an air-bubble, to incubate at blood-heat for two or three hours, and to await events. The expected happens—multitudes of living particles appear. How can we account for their origin? Three hypotheses present themselves, (*a*) that they have arisen through the reproductive multiplication of one or more germs that had escaped observation in the film; (*b*) that they have developed from a multitude of diffusely disseminated *invisible* germs; or (*c*) that they have been produced *de novo* in the fluid by a process of archebiosis. The author argues that the third interpretation is the true one. One of the arguments is based on the uniformity of nature:—

"To assume, as the great majority of Evolutionists do, that Archebiosis, or the natural origin of living matter, took place once only in the remote past and that it has not been repeated, or if repeated in past times, that it no longer goes on, is to look upon this process as a kind of natural miracle, and to postulate a break in continuity which ought only to be possible in the face of overwhelming evidence of its reality. This latter is, however, as I contend, altogether absent to anything like an adequate extent."

This kind of argument applied to other great events in evolution has the advantage of fostering an expectant attitude. Nature may be repeating herself oftener than we think.

Many of us have made flask experiments with super-heated organic fluids, which remained sterile for years without any hint of archebiosis; but, of course, these experiments only prove that living organisms do not arise under these severe conditions. We must give archebiosis a chance, and unluckily that chance usually means either an open door to infection or imperfect sterilisation. But the surer work we make with sterilisation, the greater likelihood is there of our destroying what Dr. Bastian calls the *germinality of the fluids.* When organisms do *not* appear in the sterilised medium the sceptical experimenter says "Biogenesis is confirmed," whereas he ought to say "Unluckily, I have destroyed the germinality of good archebiotic material." When organisms *do* appear in the sterilised medium the sceptical experimenter says "What an ass I am!" but if he were not so slow of heart to believe, he should say "Archebiosis for ever."

As to the original archebiosis in free nature, the author makes the suggestion that nitrate of ammonia (or nitrite?), which is formed in the atmosphere in thunderstorms and brought down by the thunder shower, may have played an important part in the mixture of ingredients in which protoplasm was first synthesised.

Dr. Bastian's patient experiments on heterogenesis raise, as it seems to us, some interesting questions concerning the variability of minute organisms, the phases in the life-history of many forms which are very inadequately known, the occurrence of "latent germs" in the interior of healthy fruits and animal organs, and so on. But we are too bigoted to believe that diatoms can be produced by the transformation of the cells of an unrelated alga, that anabena or actinophrys or amœbæ can arise from chlorophyll corpuscles, that the eggs of a fly may be transformed into infusorians, or that several different kinds of ciliata may arise from the eggs of one and the same rotifer. While all this is incredible to us because it is magical and unmeaning—incongruous with our experience of nature's workings—the difficulty is to interpret what Dr. Bastian saw and photographed. We venture the suggestion that in some of the egg-experiments he may have been on the track of ovivorous parasites such as are known to infest the eggs of some aquatic insects.

R

While we must stand aloof from Dr. Bastian's heresies, we cannot but admire his dogged support of what seems to us a lost cause. It is something to stand *unus contra mundum* with no loss of courage or of good humour. We also sympathise with some of the positions which the author maintains in the introductory part of his book, *e.g.* as to the innate or intrinsic variability of living matter, and as to the importance of discontinuous variations or mutations. There is also much vigorous criticism of Weismann's last volume, "The Evolution Theory," and a defence of Spencer's concept of "physiological units" as against Weismann's "determinants." But when, in regard to the transmission of modifications, Dr. Bastian says that "Weismann frankly admits the whole point in dispute—namely, that *acquired characters can be, and are, frequently inherited*," we must express our surprise at what seems to us an extraordinary misunderstanding. J. A. T.

A STANDARD TREATISE ON PHYSICS.

Lehrbuch der Physik. By O. D. Chwolson. Vol. iii. Translated into German by E. Berg. Pp. xi+988; illustrated. (Brunswick: Vieweg und Sohn, 1905.) Price 16 marks.

Traité de Physique. By O. D. Chwolson. Translated from the Russian and German editions into French by E. Davaux, with Notes on Theoretical Physics by MM. E. and F. Cosserat. Vol. i., part i., pp. xiii+407; vol. ii., part i., pp. vii+202. (Paris: A Hermann, 1906.) Price 16 francs and 6 francs respectively.

THE first two volumes of this important translation from Russian into German have already been noticed in these columns. The present volume embraces the science of heat, including thermodynamics. The treatment throughout is most admirable both for accuracy and lucidity, and the treatise may be expected to become generally known in this more accessible shape. Each chapter is followed by copious references to original sources of information; these are divided into sections numbered according to the parts of the text to which they relate; they constitute a valuable summary of the most important memoirs, especially as they include quite recent work as well as the earlier work which formed the foundation of the science of heat. The illustrations are excellently done.

Besides the phenomena which are usually described in a treatise on physics (thermometry, expansion, thermal capacity, laws of cooling, conductivity, general thermodynamics, and equations of state), chapters are to be found here on thermochemical investigations and the theory of solutions, including the phase rule. These are not in any way skimped. An outline of everything that is worth knowing seems to be included. The matter is not served up in a haphazard manner; but the relative value of different investigations is well brought out by the amounts of space which are devoted to them. The book is a happy mixture of theory and practice. For example, while a delightfully clear explanation is given of the meaning of the various partial differential coefficients which arise in theoretical thermodynamics, there is also given one of the very few existing correct accounts of the implication of the Joule-Thomson experiment.

The methods of Planck are followed in connection with thermodynamics. The play of entropy in irreversible transformations is made very clear; a student, by its perusal, could hardly fail to get nearer to a true conception of the nature of such processes.

The results of an investigation are not merely summed up in a formula; in most cases a table of experimental data upon which the formula is based is also provided. This, of course, is as it should be. for it puts the reader at once in touch with the actual experiment, and differentiates the volume from a mere collection of physical tables.

Altogether, we do not hesitate to say that the three volumes form as satisfactory a treatise on the part of physics to which they relate as we have ever met with. They are to be followed by a fourth volume on electricity and magnetism.

In the translation into French both the Russian and German editions are made use of, while additional notes on theoretical physics are added by MM. E. and F. Cosserat, the former of whom is a professor in the University of Toulouse. This also will appear in four volumes; the present instalment consists of parts of the first two. The additional notes will be kept quite distinct from the main text. One such note (consisting of 37 pages) now appears on the dynamics of a particle and of a rigid body. This is an attempt to re-state the principles of mechanics in such a way as to remove the difficulties pointed out by M. Poincaré in the application of mechanical principles to natural phenomena. These difficulties arise, according to Poincaré, from a too faithful application to all phenomena of the theory of the astronomical universe. The system of mechanics expounded is in general based on energetics, but a wider form than usual is given to this principle. It is impossible to criticise the theory presented until the remaining notes bearing on it have appeared.

With regard to the French edition in general we are very well pleased, and we look forward to its completion, for there are many to whom it will prove more welcome than its German equivalent. The treatise bids fair to prove itself the leading text-book of physics for general use.

CLIMBS IN WESTERN CANADA.

In the Heart of the Canadian Rockies. By James Outram. Pp. 466; with maps and 46 illustrations. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1905.) Price 12*s.* 6*d.* net.

IN the "Apology" with which this volume is prefaced, the author tells how he went to the mountains during a part of three summers to recuperate from mental overstrain, and states that he has been hampered by the same disability in preparing his book. Nevertheless, he has succeeded in producing a useful piece of work, which brings together an account of all that has been accomplished in the

Canadian Rockies by himself and by other kindred spirits.

Though essentially and avowedly a mountain-climber's book, it incidentally places before the reader much information regarding the physical geography of an imperfectly known region that is full of interest. The author's sympathy in the natural beauty of this magnificent country is expressed simply and moderately, and his descriptions therefore, though not particularly vivid, ring true. The aim and effort of his toilsome journeyings was ever to reach the mountain-tops—preferably the tops hitherto untrodden—and all other considerations were subordinate to this desire. How difficult often was the attainment, and yet how great was his success, is faithfully chronicled in these pages. Along the main chain of the Rockies—those huge stratified wedges left by Nature's Quarriers to show how much has been excavated from Mount Columbia (12,500 feet) in the north to Mount Lefroy (11,290 feet) in the south, and also on the crests of the Ottertail Range outstanding to the west—Mr. Outram and his Swiss guides have scored their innocent conquests and have brought back increased knowledge of forests, glaciers, snow-fields, and craggy peaks.

By conveniently interweaving in his narrative full extracts from the records of other explorers, the author enables us to recognise the salient features of this wilderness of mountains, and in so doing to increase our sense of enjoyment in them. For, as the author has noted, it is curious how, when confronted by some wide and novel prospect, we instinctively search for some feature already known, upon which our new perceptions may form themselves; and great is the relief to our confused senses as soon as a recognisable point is found. In mountain scenery, lack of familiarity usually implies also lack of that knowledge of distances and heights which is an essential ingredient to the full impressiveness of the prospect: for it is not the low-angled picture in the eye, but the interpretation of it, that stirs emotion. The ancients did not know their mountains well enough to appreciate them.

For the same reason it is essential that mountains should have names; but it seems deplorable that almost all the peaks of the Canadian Rockies should have had meaningless personal names attached to them. Better the most tongue-twisting native term or the most bizarre appellation of the backwoodsman! Yet it must be admitted that we agree with the author in desiring something less cumbrous than "The West Branch of the North Fork of the North Saskatchewan" as the name for a stream!

The book is well illustrated by reproductions from photographs of many of the mountains and other striking features in the scenery of the region. But photographs of this kind, and still more the process-illustrations prepared from them, yield only a feeble image, useful perhaps as a reminiscence to anyone who has experienced the scene, but always unsatisfying.

By an evident oversight, no scale is attached to the two maps interleaved in the text, though these are not on the same scale as the folder at the end of the volume. And is it by accident or design that the seven-line quotation of Sir Edwin Arnold's verse which is given at the beginning of the first chapter of the book is repeated, with a slight variation, at the end of the last chapter?

G. W. L.

SCIENCE AND ART OF CARPENTRY.

A Manual of Carpentry and Joinery. By J. W. Riley. Pp. viii + 500. (London: Macmillan and Co., Ltd., 1905.) Price 6s. net.

THIS is a handy little volume on a well-worn subject, about which there are many works extant, but it contains a good deal of useful information for the student in one of the noblest of the crafts. It was Lord Avebury who compared wood to metal, and dwelt on the higher qualities of the former material as a field for the perpetuation of the more enduring forms of art.

The present manual, besides dealing with the various operations of the carpenter, starts with the consideration of geometry, mensuration, and mechanics as a necessary preliminary for his education if he would work with benefit to himself and his employers. The qualities of various kinds of timber, its structure and growth, method of conversion, defects, and preservation are explained. Chapters on plane and solid geometry and mensuration in relation to carpentry follow, and these are probably the best chapters in the book, because of their importance to the student in their relation to the craft.

The chapter on tools is well illustrated—saws, planes, chisels, gouges and centre bits being shown. The inclusion of wood-working machinery is an innovation which will be welcomed because of the increasing importance of machinery in these days. This chapter is also well illustrated with woodcuts of sufficiently large size to render them useful and explanatory. In fact, although some might say that machines are hardly a part of a student's education, we think the author is right in including them, and it certainly is a novel feature in a text-book for elementary students. Joints and fastenings in floors, roofs and beams, dovetails of various forms used in joinery, and keying and clamping are then described.

The various kinds of wooden floors, the method of "trimming" round fireplaces, and the joints of different kinds between floor boards are also dealt with. We should like to have seen a condemnation of the usual system of constructing floors with a hollow space between floor boards and plaster ceiling, forming a series of continuous dustbins for the collection of filth of all kinds. Many architects frequently omit the plaster ceiling altogether.

The usual types of wooden roofs and trusses and the method of finding bevels for rafters at different inclinations, the different kinds of partitions, scaffolding, jib cranes, shoring of buildings, are all parts of the craft which Mr. Riley has carefully explained with illustrations. The chapter on the mechanics of carpentry and the theory of the parallelogram of

forces, the use of a polar diagram and its application to weighted beams are clearly set out.

Door and panelled framing, revolving vestibule doors, hinges and locks, and the different varieties of windows, sash or casement are explained and illustrated. We cannot understand why writers on the subject are always content to show window frames "in reveal" when they appear to so much better advantage only slightly set back from the face of the wall, as in "Queen Anne" and "Georgian" architecture, and as carried out by so many of the best architects of to-day.

There are also chapters on roof lights and conservatories, staircase work and handrailing, and workshop practice, together with summaries and questions from papers set at the City and Guilds examinations in the subject.

OUR BOOK SHELF.

Die Explosivstoffe mit besonderer Berucksichtigung der neuren Patente die Schiessbaumwolle (Nitrocellulosen). By Dr. Richard Escales. Pp. viii+308. (Leipzig: Veit and Co.) Price 10 marks.

THIS is the second volume of a series of special works on explosives. Although the first volume on "Gunpowder and Similar Mixtures" was issued as recently as 1904, it has been found necessary to prepare a new edition, and doubtless the first edition of the volume under consideration will soon be exhausted. The whole series when completed should form a valuable reference work on all subjects relating to explosives.

The book is thoroughly up to date, and reference will hardly be in vain for any information either as to details of manufacture or the more purely scientific questions relating to nitrocellulose or closely allied bodies. The testing of guncottons to determine their stability and the influence of methods of preparation on this have received a great deal of attention during the last three or four years, since it is generally recognised that the older stability tests are often unsatisfactory when taken alone. The author has collected and arranged in excellent form all possible information on this important matter up to quite a recent date.

Special reference is made to new patents, and this information will be of great service to those engaged in the manufacture of this important class of bodies.

J. S. S. B.

Lehrbuch der technischen Physik. By Prof. Hans Lorenz. Zweiter Band, Technische Warmelehre. Pp. ix+544. (Munchen: R. Oldenbourg, 1904.)

THE first volume of this text-book, dealing with the mechanics of solids, appeared some three years ago. It was to have been followed by a volume on hydromechanics, but this has been delayed to include later developments, and its place has been taken by the present volume on heat, which was originally intended to come third in the series. The general scope of the book is similar to that of the first volume. It is not a "technical" handbook as we understand it. There are no descriptions or figures of machines, or even of instruments for measurement. There are no details of experimental methods, nor any mention of precautions necessary for securing accurate results. The whole work is as purely theoretical as any Cambridge mathematical text-book; but the theory is limited to such parts of the subject as have practical applications, with a few numerical tables introduced here and there for the comparison of the equations with experimental results. Such a book might be written by anyone of sufficient mathematical ability without any practical knowledge of the subject, and might be thoroughly assimilated by the student without imparting to him any power of applying the theory to a practical case. One cannot help feeling that, in a subject where so much depends on experiment, and for the technical student who wishes to learn how to apply his knowledge, the utility of the book would be greatly enhanced by a judicious admixture of practice with the theory.

From the purely theoretical standpoint there are many details which are open to criticism. Empirical and theoretical formulæ are in places so interwoven that the student would find it very difficult to disentangle the theory from the consequences of some purely empirical assumption. Though one would certainly hesitate to recommend the book to the technical student wishing to learn how to apply the theory, it might provide him with a useful kind of mental discipline, and prove a good antidote to the more common kind of technical treatise in which experimental results are reduced to a series of purely empirical and often theoretically inconsistent formulæ.

H. L. C.

The Making of East Yorkshire: a Chapter in Local Geography. By T. Sheppard. Pp. x+29; 4 plates. (London: Brown and Son, 1906.) Price 1s.

THE teachers of Yorkshire are blessed by nature with an environment of abounding interest; added to this they have, what is equally to their advantage, a goodly supply of able exponents of nature's beauties, amongst whom the author of this brochure takes a worthy place.

Mr. Sheppard gives a clear account of the geological vicissitudes through which east Yorkshire has passed from Liassic to recent times. He has naturally selected the salient points, but a word or two about the conditions which governed the deposition of some of the argillaceous deposits would have resulted in a better balanced story. The imaginative reader who attempts to visualise the statement at the foot of p. 20 will be presented with an awesome and none too truthful picture—but this is quite a small matter.

Every teacher in east Yorkshire should possess a copy of the pamphlet; and it would be an excellent thing if our other counties could each be supplied with a similar sketch of their geological history.

J. A. H.

Jahrbuch der Chemie. Edited by Richard Meyer. Pp. xii+589. (Brunswick: Vieweg und Sohn, 1905.) Price 16s.

WE have previously had occasion to commend Meyer's "Jahrbuch" to English readers, and the new volume compares favourably with its predecessors.

That lucidity in some of the abstracts is sacrificed to brevity naturally follows from the vast amount of information which is compressed into a limited space; after all, one valuable feature of a year-book is the completeness of its references. It has been previously observed that the "Jahrbuch" has a distinctly German bias, which, perhaps, cannot be entirely repressed, but scarcely excuses the omission in the present volume of references to certain foreign memoirs of the first importance.

An apology for its late appearance accompanies the volume, and we are led to infer that the delay may have been occasioned in some measure by the regrettable loss of Dr. Bodländer from the staff of contributors, whose place, it may be added, on the section of physical chemistry is now taken by Dr. A. Coehn.

J. B. C.

Elements of Applied Microscopy. By Charles-Edward Amory Winslow. Pp. xii + 183. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 6*s.* 6*d.* net.

This little book is planned on novel lines, and contains a good deal of information in a small compass. As it is primarily intended for class use, practical details are briefly dealt with, and more space is thus available for descriptions of the various objects which the microscopist is intended to study. The first three chapters deal with the theory, construction, and manipulation of the microscope, and the preparation and mounting of objects. Next, micrometry and the camera lucida are described, and the subsequent chapters are devoted to the microscopy of starches, of foods and drugs and their adulterants, the examination of textile fibres and of paper, forensic microscopy, microchemistry, and petrography and metallography. Sufficient information is given to stimulate the student's powers of observation and desire for further knowledge. The chapter on the microscopy of paper is a particularly good one. Altogether the book should usefully fulfil the object for which it has been written.

Auslese aus meiner Unterrichts- und Vorlesungspraxis. By Dr. H. Schubert. Zweiter Band. Pp. 218. (Leipzig: Göschen, 1905.) Price 4 marks.

This is a very entertaining instalment of Prof. Schubert's lectures. The first section deals with triangles having rational sides and areas, pyramids with rational edges and volumes, and similar subjects. Tables and formulæ are given which will be useful to those who wish to set neat numerical exercises in trigonometry and mensuration. Section ii. is devoted to continued fractions, the Pellian equation, expression of an integer (when possible) as the sum of two squares, and so on. Section iii. is on the elementary calculation of logarithms, and forms a supplement to a similar chapter in the first volume.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Secondary Röntgen Rays and Atomic Weight.

In papers on secondary Röntgen radiation and polarised Röntgen radiation I have shown that all the phenomena of secondary radiation (as indicated by an electroscope placed several centimetres from the radiator) may, from substances of low atomic weight, be accounted for by considering the corpuscles or electrons constituting the atoms, to be accelerated in the direction of electric displacement in each primary Röntgen pulse as it passes through such substances, and that the interaction between the corpuscles affects only to a small extent the character of the secondary radiation proceeding from the substance. In light atoms there is almost complete independence of motion of the corpuscles within the limits of disturbance produced by all primary beams experimented upon.

It was also shown (Nature, March 9, 1905) that this independence of motion disappears in heavier atoms in which there may be conceived to be a more intimate relation between the corpuscles, inter-corpuscular forces being brought into play which have the effect of widening the secondary pulses and producing accelerations in the corpuscles in directions other than those of electric displacement in the primary pulse. Until recently I have been unable to make experiments on a sufficient number of elements of higher atomic weight to arrive at any law connecting the penetrating power of the secondary radiation with the atomic weight of the radiator. Recent investigation has, however, shown that beyond the region of atomic weights in which the character of secondary radiation is almost independent of the nature of the radiator, the absorbability of the radiation is a periodic function of the atomic weight, the periodicity agreeing so far as these experiments have gone with the periodicity in chemical properties.

A detailed account of these results will be published shortly.

They, however, afford striking evidence of a connection between chemical properties and distribution of corpuscles in the atom, such as Prof. J. J. Thomson suggests in his conception of the constitution of the atom; for the character of the secondary radiation set up by a given primary can only, according to the theory which has been shown to account for all the phenomena I have hitherto observed, be affected by the relation between the radiating corpuscle and its neighbours.

The results also suggest a method of determining atomic weights by interpolation, for a small variation in atomic weight is usually accompanied by a very considerable change in absorbability of the secondary radiation, and though in these experiments great accuracy has not been essential, it appears that in many regions a variation of atomic weight by much less than 1 would be indicated.

The experiments are being continued.

Charles G. Barkla.

University of Liverpool, February 9.

The Falkland Island Fox.

In a review in the current number of Nature of Mr. Renshaw's "Some Mammalian Types," reference is made to the "Antarctic wolf of the Falkland Islands exterminated by the sheep farmers in self defence." Might I be permitted to add a word on this subject in correction of an erroneous impression current among many naturalists with regard to this animal? During a visit to the Falkland Islands in 1903, and again in 1904, I made careful inquiries with regard to the native wolf or fox. The oldest sheep farmers in the islands, men who remembered when the fox was still plentiful, insisted that it was quite a mistake to credit it with attacking sheep; this never occurred, and the reason that the farmers waged war against the foxes was because the sheep, apparently mistaking them for dogs, especially at night, in their terror ran into the bogs and swamps which abound in the islands and were consequently lost. None of the farmers whose experience went back to the time of these foxes had any memory of sheep being killed or even mauled by them. In making this correction, I must say that I have not seen Mr. Renshaw's book, and consequently do not know what reason he attributes for the extermination of the fox.

R. N. Rudmose-Brown.

Scottish National Antarctic Expedition, Edinburgh, February 10.

Chinese Names of Colours.

On the interesting observation on Chinese names of colours of Mr. H. Crook, in Nature (January 11), I would add this little information. Prof. Giles in his great dictionary gives (No. 4845) 雪青 as "a very light violet colour"; Wells Williams (p. 820) as "a purple colour." Mr. de Zelinski and Clémence Royer, in an interesting note "Sur les noms des couleurs en japonais" ("Congrès internat. des Orientalistes, Compte rendu de la 1ère session, Paris, 1873, vol. i., pp. 83–87), give another example, in Japanese, of the same kind.

浅葱 (*asagi*), literally "*a light yellow*," signifies, following Prof. de Rosny, "*bleu de ciel*"! Mr. Hepburn, in his Japanese dictionary, fifth edition, Tokyo, 1894, renders the same expression by "*a light green or pale colour.*"

Analogous oddities can also be found in European languages, as the French "*azur cendré*," or "*une rose* (the flower) *jaune*," &c.

Firenze, Via Ricasoli 49, Italy.

NOTES ON SOME CORNISH CIRCLES.

The Merry Maidens, Lat. 50° 4′ N.

ONE of the best preserved circles that I know of is near Penzance. It is called the Merry Maidens[1] (Dawns-Maen), and is thus described by Lukis[2] (p. 1):—

"This very perfect Circle, which is 75 feet 8 inches in diameter, stands in a cultivated field which slopes gently to the south.

"It consists of 19 granite stones placed at tolerably regular distances from each other, but there is a gap on the east side, where another stone was most probably once erected.

"Many of the stones are rectangular in plan at the ground level, vary from 3 feet 3 inches to 4 feet in height, and are separated by a space of from 10 to 12 feet. There is a somewhat shorter interval between four of the stones on the south side.

"In the vicinity of this monument are two monoliths called the Pipers; another called Goon-Rith; a holed stone (not long ago there were two others); and several [5] Cairns."

Lukis thus describes "the Pipers":—

"Two rude stone pillars of granite stand erect, 317 feet apart, and about 400 yards to the north-east of the Circle of Dawns-Maen. No. 1 is 15 feet high, 4 feet 6 inches in breadth, and has an average thickness of 22 inches, and is 2 feet 9 inches out of the perpendicular. The stone is of a laminated nature, and a thin fragment has flaked off from the upper part. No. 2 is 13 feet 6 inches high, and is much split perpendicularly. At the ground level its plan in section is nearly a square of about 3 feet."

Goon-Rith is next described:—"No 3 is naturally of a rectangular form in plan, and is 10 feet 6 inches in height. The land on which it stands is called Goon-Rith, or Red Downs. The upper part of the stone is of irregular shape."

Borlase, in his "History of Cornwall" (1769), only mentions the circle, but W. C. Borlase in his "Nænia Cornubiæ" (1872) gives a very rough plan including the stones before mentioned and several barrows, some of which have been ploughed up.

At varying distances from the circle and in widely different azimuths are other standing stones, ancient crosses and holed stones, while some of the barrows can still be traced.

The descriptions of the locality given by Borlase and Lukis, however, do not exhaust the points of interest. Edmonds[1] writes as follows:—

"A cave still perfect . . . is on an eminence in the tenement of Boleit (Boleigh) in St. Buryan, and about a furlong south-west of the village of Trewoofe (Trove). It is called the 'Fowgow,' and consists of a trench 6 feet deep and 36 long, faced on each side with unhewn and uncemented stones, across which, to serve as a roof, long stone posts or slabs are laid covered with thick turf planted with furze. The breadth of the cave is about 5 feet. On its north-west side, near the south-west end, a narrow passage leads into a branch cave of considerable extent, constructed in the same manner. At the south-west end is an entrance by a descending path; but this, as well as the cave itself, is so well concealed by the furze that the whole looks like an ordinary furze break without any way into it. The direction of the line of this cave is about north-east and south-west, which line, if continued towards the south-west, would pass close to the two ancient pillars called the Pipers, and the Druidical temple of Dawns Myin, all within half of a mile."

Photo. by Lady Lockyer.

FIG. 1—The Merry Maidens (looking East).

This fougou is situated on a hill on the other side of the Lamorna Valley, near the village of Castallack, and the site of the Roundago shown in the 1-inch ordnance map.

Borlase[2] says that many similar caves were to be seen "in these parts" in his time, and others had been destroyed by converting the stones to other uses.

There is evidence that the circle conditions at the Merry Maidens were once similar to those at Stenness, Stanton Drew, the Hurlers, Tregaseal, and Botallack, that is that there was more than one, the numbers running from 2 to 7. Mr. Horton Bolitho, without whose aid in local investigations this paper in all probability would never have been written, in one of his visits came across "the oldest inhabitant," who remembered a second circle. He said, "It was covered with furze and never shown to antiquarians"; ultimately the field in which it stood was

[1] I may here remark that "9 maidens" is very common as a name for a circle in Cornwall. It is a short title for 19 maidens. Lukis implies that Dawns-Maen once consisted of 20 stones. If all the circles followed suit it would be interesting to note if the oresent number of 19 is always associated with a gap on the eastern sides. The "pipers" are, of course, the musicians who keep the maidens merry, as does the "blind fiddler" at Boscowen-un Circle.

[2] "Prehistoric Stone Monuments, Cornwall.

[1] "The Land's End District," p. 46.

[2] "Antiquities," p. 274.

ploughed up and the stones removed. It is to prevent a similar fate happening to the "Merry Maidens" themselves that Lord Falmouth will not allow the field in which they stand to be ploughed, and all antiquarians certainly owe him a debt of gratitude for this and other proofs of his interest in antiquities. Mr. Bolitho carefully marked the site thus indicated on a copy of the 25-inch map. I shall subsequently show that the circle which formerly existed here, like the others named, was located on an important sight-line.

Mr. Horton Bolitho was good enough to make a careful examination of the barrows A and B of Borlase.[1] In A (S. 69° W.) he found a long stone still lying in the barrow, suggesting that the barrow had been built round it, and that the apex of the barrow formed a new alignment. In B there is either another recumbent long stone or the capstone of a dolmen. This suggests work for the local antiquarians.

I should state that there may be some doubt about barrow A, for there are two not far from each other with approximate azimuths S. 69° W. and S. 64° W. The destruction of these and other barrows was probably the accompaniment of the reclamation of waste lands and the consequent interference with antiquities which in Cornwall has mostly taken place since 1800.

But it did not begin then, nor has it been confined to barrows. Dr. Borlase in his parochial memoranda under date September 29, 1752, describes a monolith 20 feet above ground, and planted 4 feet in it, the "Men Peru" (stone of sorrow) in the parish of Constantine. A farmer acknowledged that he had cut it up, and had made twenty gate-posts out of it.

My wife and I visited the Merry Maidens at Easter, 1905, for the purpose of making a reconnaissance. Mr. Horton Bolitho and Mr. Cornish were good enough to accompany us.

On my return to London I began work on the 25-inch Ordnance map, and subsequently Colonel R. C. Hellard, R.E., director of the Ordnance Survey, was kind enough to send me the true azimuths of the Pipers. In October, 1905, Mr. Horton Bolitho and Captain Henderson, whose help at the Hurlers I have already had an opportunity of acknowledging, made a much more complete survey of the adjacent standing stones and barrows.

In this survey they not only made use of the 25-inch map, but of the old plan given by W. C. Borlase dating from about 1870. Although the outstanding stones shown by Borlase remain, some of the barrows indicated by him have disappeared.

In January, 1906, my wife and I paid other visits to the monuments, and Mr. Horton Bolitho was again good enough to accompany us. Thanks to him permission had been obtained to break an opening in the high wall-boundary which prevented any view along the "Pipers" sight-line. I may here add that unfortunately in Cornwall the field boundaries often consist of high stone walls topped by furze, so that the outstanding stones once visible from the circles can now no longer be seen from them; another trouble is that from this cause the angular height of the sky-line along the alignment cannot be measured in many cases.

I will now proceed to refer to the chief sight-lines seriatim. The first is that connecting the circle which still exists with the site of the ancient one. On this line exactly I found four points, a barrow (L) which Borlase had missed (further from the circle than his barrow A), the site, the present circle, and the fougou; azimuth from centre of circle N. 64° E. and S. 64° W. This is the May year line found at Stonehenge, Stenness, the Hurlers and Stanton Drew.

In connection with this there is another sight-line which must not be passed over; from the circle the bearing of the church of St. Burian is about N. 64° W.; like the fougou it is situated on a hill, and near it are ancient crosses which I suspect were menhirs first and crosses afterwards.[1] However this may be, we see in this azimuth of 64° three times repeated that the May and August sunrises and sunsets and the February and November sunsets were provided for.

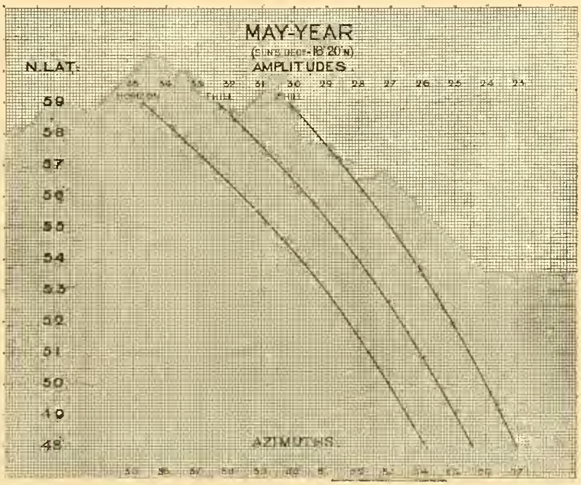

FIG. 2.—The place of the May sunrise in British latitudes.

With regard to the other sight-lines I will begin with that of the Pipers as it is quite obviously connected with the eastern circle only; the stones could not have been seen from the other on account of rising ground. The barrow shown in this direction by Borlase has now entirely disappeared, and the earth has evidently been spread over the surrounding field; its surface is therefore higher than formerly, so that when the opening was made in the wall the top of the nearest piper could not be seen from the centre of the circle; an elevation of about 2 feet from the

[1] "Nænia," p. 214.

[1] In A.D. 658 a council assembled at Nantes decreed:—"As in remote places and in woodlands there stand certain stones which the people often worship, and at which vows are made, and to which oblations are presented—we decree that they be all cast down and concealed in such a place that their worshippers may not be able to find them."

"Now the carrying out of their order was left to the country parsons, and partly because they had themselves been brought up to respect these stones, and partly because the execution of the decree would have brought down a storm upon their heads, they contented themselves with putting a cross on top of the stones."—"Book of Brittany," by Baring-Gould, p. 20.

ground level was necessary. Walking straight from the circle to the first piper, the second piper was exactly in a line, though at a much lower level. This showed that the ordnance values were not quite accurate, which was not to be wondered at as no direct observation had been possible. I therefore adopted the mean of the ordnance values as the true azimuth:—

	°	′	″	
Piper 1.—N.	37	58	36	E.
Piper 2.—	38	52	36	
Mean	38	25	36	

The sky-line from the centre of the circle was defined by the site of the vanished barrow, angular elevation 20′, and it is highly probable that the function of the barrow when built was to provide a new sight-line when the star-rise place was no longer exactly pointed out by the piper line.

With these data the star in question was Capella, dec. 29° 58′ N., heralding the February sunrise, 2160 B.C.

I next come to the famous menhir Goon-Rith. The conditions are as follows: from the circle Az. S. 81° 35′ W. Altitude of sky-line 34′.

Concerning this alignment from the circle, it may be stated that it cuts across many ancient stones, including one resembling a rock basin or laver, and another either a holed stone or the socket of a stone cross. I suspect also the presence in old days of a holy well attached to the circle, for there is a pool of water in a depression which is shown in the 25-inch map.

I regard it as quite possible that we are here in presence of the remains of a cursus, an old *via sacra*, for processions between the circle and the monolith.

I have not been able to find any astronomical use for this stone from the circle or from the site of the old one, but if we suppose it to have been used like the Barnstone at Stenness for observations *over* the circle its use at once becomes obvious.

From the azimuth given, the declination of the star was 5° 24′ N. Now this was the position of the Pleiades B.C. 1960, when they would have warned the rising of the May sun.

So that it is possible that the erection of the Pipers and of Goon-Rith took place at about the same time, and represent the first operations.

The next alignment has an azimuth of S. 69° W.; from the circle, it would be the same within a degree from the site of the one which has disappeared, altitude of sky-line 18′; this line is to a stone cross on rising ground, doubtless a re-dressing of an old menhir, and on the line nearer the circle are the remains of a barrow.

With these data the star in question was Antares, dec. S. 13° 18′, heralding the May sunrise 1310 B.C.

There is another stone cross defining a line az. N. 11° 45′ E. from the circle, altitude of sky-line about the same as along the piper azimuth; an intervening house prevents measurement. These values give us N. dec. 38° 46′, referring to Arcturus warning the August sunrise in 1640 B.C.

The three alignments already referred to, then, give us the warning stars for three out of the four quarter days of the May year, the astronomical conditions of which in Cornwall are shown in the accompanying diagrams.

NORMAN LOCKYER.

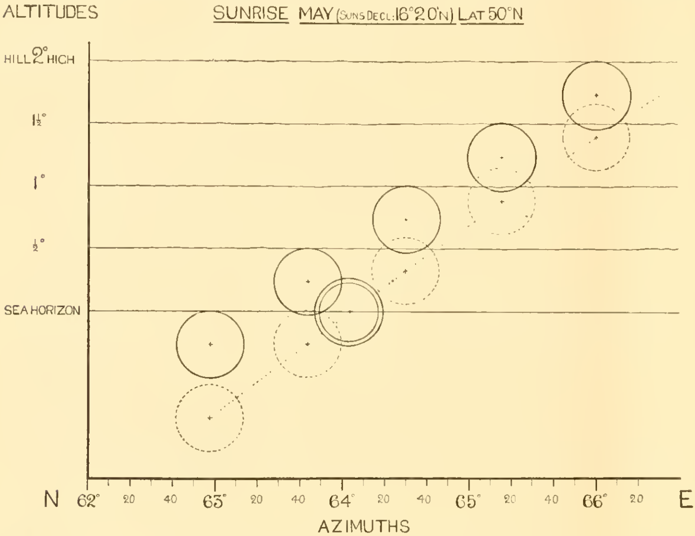

FIG. —Showing the influence of the height of the sky-line on the apparent place of sunrise. The double circle shows the tabular place of sun's centre.

THE SERUM THERAPY OF PLAGUE.

THE discovery of diphtheria antitoxin and the excellent results obtained with it in practice, which in the Metropolitan Asylums Board hospitals has resulted in a reduction in the case-mortality from about 29 to 11 per cent., raised hopes that a panacea had at last been found for all microbic diseases. But it must be confessed that expectations have not been realised, and as regards other therapeutic sera none has proved nearly so efficacious as the diphtheria serum.

Several reasons may be given for this. The antitoxic sera, *i.e.* therapeutic sera prepared by the injection of bacterial toxins, are much more potent than anti-microbic sera, and possess antidotal properties proportional to their strength. But unfortunately most micro-organisms do not produce an extra-cellular toxin, like the diphtheria bacillus does; the toxic substances are more or less intimately associated with the bacterial cells, as in staphylococcic and streptococcic (septic) infections, typhoid, plague, &c. Now

the anti-microbic sera seem to neutralise through the interaction of two substances, one present in the serum, the other a constituent of the patient's body and limited in amount, so that when the whole of the latter has taken part in the neutralisation, no additional amount of the therapeutic serum produces a further neutralisation.

Again, an anti-streptococcic serum prepared with streptococcus A, though active against A, does not necessarily neutralise another streptococcus B. In diphtheria also, a local and visible lesion generally enables a diagnosis to be made, and serum treatment to be applied, before any great amount of tissue damage has been done, whereas in tetanus, for which a very potent antitoxin has also been prepared, it is the results of tissue damage which lead to a diagnosis. No therapeutic serum can, of course, *repair* tissue damage, and if this has proceeded beyond a certain degree the condition becomes incompatible with life. It is noteworthy that even in diphtheria, if treatment be delayed beyond the third day, antitoxic treatment produces results little better than treatment without antitoxin, tissue damage having proceeded to too great an extent during the interval.

The fearful prevalence of plague in India during the last few years, which has caused the death of hundreds of thousands of the inhabitants of that great Empire, has naturally directed attention to the serum therapy of this disease, since no ordinary form of treatment has any particularly beneficial effect, and the Government of India has therefore been well advised to devote one of its scientific memoirs [1] to the subject, under the editorship of Lieut.-Col. Bannerman, M.D., I.M.S., who has had much experience of plague. Various forms of anti-plague serum were the subjects of trial, the Roux-Yersin, Lustig, Haffkine, Terni, and Brazil, the details of the preparation of which are given, and tables of the results obtained. Col. Bannerman concludes from a study of the circumstances and of the case-mortality of the various series of cases treated with the different sera that (1) the Roux-Yersin serum did not affect the case-mortality in the slightest degree, (2) in three out of the four trials made with Lustig's serum the case-mortality of the serum cases was higher than among those receiving ordinary treatment, (3) with Haffkine's serum there is no certain evidence of its efficiency, (4) with Terni's serum there is a difference of 0.91 per cent. only in favour of the serum-treated cases, and (5) with Brazil's serum, though there is a difference of 2.85 per cent. in favour of the serum-treated cases, it is problematical if this can definitely be ascribed to the serum.

As regards case-mortality, therefore, these trials do not suggest that serum therapy in plague is of much, if of any, value, but clinically there is an amelioration in the symptoms, and the cases when treated with serum live for a longer period than without it. We might add that the series of cases treated with Terni's and with Brazil's serum (110 and 70 respectively) are too small to warrant any definite conclusions. Bannerman from these results considers that it will be necessary to commence anew the study of the serum therapy of plague, and with this we cordially agree. At the same time we cannot help thinking that it would be desirable to make a much more extended use than has been done of the intravenous method of administration of the serum.

R. T. HEWLETT.

[1] *Scientific Memoirs of the Government of India*, No. 20, 1905. Serum Therapy of Plague in India. Reports by Mr. W. M. Haffkine, C.I.E., and various Officers of the Plague Research Laboratory, Bombay. Edited with an Introduction by Lieut.-Col. Bannerman, M.D., B.Sc., I.M.S., Director, Plague Research Laboratory, Bombay.

SEA COAST PROTECTION.

A CONFERENCE of local authorities having districts situated on the seaboard of England was held in London on February 6 on the subject of the defence of the coasts against erosion by the sea, and the national responsibility in regard to the matter. This conference was convened by the chairman of the Herne Bay District Council. The matter had been taken up by the sea-side towns on the east coast in 1903, and a deputation was then appointed to wait on Mr. Balfour, but nothing came of this. The conference recently held consisted chiefly of representatives of towns on the south coast, and a resolution was adopted "That representatives of this conference be appointed to approach the Prime Minister and President of the Board of Trade, to request the Government to introduce into Parliament a Bill declaratory of the aforementioned principles and defining ways and means whereby some relief towards, or allowance in respect of, the cost and maintenance of protective works might be contributed by the Government." The report of the meeting that appeared in the public journals does not say what "the aforementioned principles" consist of.

The members who attended this conference consisted almost entirely of representatives of sea-side towns, where promenades and similar works have been constructed for the purpose of enhancing the attractions of these places.

The *Engineer*, in an article on this conference, points out that to protect efficiently long stretches of purely agricultural land, the sea margin of which consists of friable and easily eroded material exposed to the inroads of the sea, would (as shown in the book on "The Sea Coast," published by Messrs. Longmans and Co.) involve a capital and maintenance expenditure out of proportion to the advantages secured, the value of the land preserved during the life of the protective works not being equal to one-third of the outlay required for protecting it.

In the case of sea-side resorts or other localities where the coast-line is of considerable value, the *Engineer* points out that while the preservation of the littoral is an absolute necessity, the benefits to be derived by protection are almost wholly local, and the owners of agricultural land not worth the cost of protection would have a perfectly legitimate grievance if Imperial funds were spent for the benefit of their wealthier neighbours. It may also be added that all inland towns would have an equal right to protest against contributing towards money spent on these sea-side towns, where promenades and other works have been constructed to attract visitors, and thereby have enormously increased the value of the property of those whose land is adjacent.

There was one part of the subject of coast erosion alluded to at the meeting which might with more reason be pressed on the attention of the Government, that is, the prevention of the removal of sand and shingle from the beach, which now forms a natural protection to the shore. As the law now stands, the Board of Trade, on being applied to, will order a local inquiry where complaint is made of injury done by such removal, and if as the result of such inquiry it is shown that such removal is injurious, the Board can, under its statutory powers, issue an order forbidding any further removal. The cost of these inquiries, however, is considerable.

In some cases the Government itself is the offender, shingle being taken for making concrete for its coast works. In many cases the local authorities, who are now asking for State relief, have been the worst offenders in this respect, by placing their sea walls so

as to shut in the natural shingle banks behind the walls or using the material from them for their works.

The Government might justly be asked to obtain such an alteration in the existing law as would make any removal unlawful unless it could be shown that such removal would not in any way be injurious to adjacent property, and making it the duty of the coastguards to report where any removal of shingle or sand is taking place.

NOTES.

THE present year will witness the fiftieth anniversary of the foundation of a great branch of chemical industry which, perhaps more than any other discovery in applied chemistry, has reacted upon the science itself to its lasting benefit. Half a century ago the first artificial colouring matter obtained from a coal-tar product was discovered and manufactured by William Henry Perkin under the trade name of "Mauve." The subsequent development of the coal-tar colour industry has been one continuous series of triumphs, and the colossal scale on which organic compounds of great complexity are now manufactured, often in a state approaching chemical purity, cannot but strike the future historian of scientific industry as one of the most marvellous achievements of applied organic chemistry of the present age. The marvel is enhanced when it is borne in mind that the whole of this industrial development, which has been made possible by the intervention of pure science at every stage, has taken place during the last half-century. The founder of the industry, Dr. Perkin, is happily still with us in full vigour, and a movement is now being organised to celebrate the jubilee of the discovery and to do honour to the discoverer. Preliminary meetings have been held under the auspices of the Chemical Society and a provisional committee formed, which committee has prepared a scheme for submission to a public meeting for adoption at the Mansion House on February 26 at 3 p.m., when the Lord Mayor has consented to take the chair. That the importance of the movement is being appreciated in this country is shown by the fact that, in addition to all the leading chemists and manufacturing chemists, the committee already comprises the names of Lords Halsbury, Rayleigh, Alverstone, and Avebury, the Right Hons. R. B. Haldane, A. J. Balfour, and Joseph Chamberlain, and representatives of the universities, Royal Society, the City companies, &c. The appreciation, moreover, is not limited to Perkin's own countrymen, and it is known that when the scheme has been formally adopted at the Mansion House meeting on February 26 other countries, and especially Germany, the present headquarters of the industry, will participate in the movement. Those who are interested in the scheme are invited to attend the meeting. The secretary to the committee is Prof. A. G. Green, of Leeds University, from whom particulars can be obtained.

A PORTRAIT of Dr. H. C. Sorby, F.R.S., subscribed for privately, and presented by the subscribers to the University of Sheffield, in commemoration of Dr. Sorby's scientific work and labours as one of the founders of the university, was unveiled on Monday, in the presence of a large assembly of leading citizens and other admirers of his devotion to scientific research and to the cause of higher education in Sheffield. Alderman Franklin, as president of the university council, opened the proceedings, and the portrait was unveiled by the Lady Mayoress. Mr. Simeon Snell and Prof. W. M. Hicks, F.R.S., who organised the movement for the presentation, in asking the University to accept the portrait, referred to Dr. Sorby's long association with Sheffield—he might, in fact, be regarded as the Dalton or the Priestley of Sheffield—and to his sixty years of active work for the advancement of science and the extension of natural knowledge. The state of Dr. Sorby's bodily health prevented him from being present at the ceremony, but he expressed his appreciation of the honour in a letter to Alderman Franklin. The portrait is a replica of one painted by Mrs. M. L. Waller, and now hanging in the rooms of the Sheffield Literary and Philosophical Society.

THE gold medal of the Royal Astronomical Society has this year been awarded to Prof. W. W. Campbell, of the Lick Observatory, for his spectroscopic researches on the motions of stars in the line of sight. The medal was presented at the eighty-sixth anniversary meeting of the society on February 9, when the American Ambassador, Mr. Whitelaw Reid, received the medal on behalf of Prof. Campbell, who was unable to be present. Mr. Whitelaw Reid, in accepting the medal on Prof. Campbell's behalf, said he would certainly value the decoration as highly as a soldier or statesman would value one sent him by a Sovereign. The United States is proud of every advance in art or science made by her sons—prouder of these than of triumphs in trade or in war—and it will be gratified that this high recognition for service to one of the noblest of sciences came from a land to which they are so closely related.——It may be remarked that this is the third consecutive year that this medal has been awarded to an American astronomer. In fact, Mr. Choate, the late American Ambassador, in receiving the medal for Prof. Lewis Boss last year, remarked that it seemed quite one of the annual duties of the Ambassador to proceed to the rooms of the Royal Astronomical Society to receive the gold medal. Out of the list of the last thirteen medallists, no less than seven hail from the United States.

ACTIVE steps are being taken at York to ensure the success of the meeting of the British Association to be held there next August. Last Saturday, at a large and distinguished assembly, over which the Lord Mayor of York presided, the arrangements in connection with the forthcoming visit were advanced a further stage. A reception committee representative of the city and county was elected, and it was resolved to raise a fund of not less than 250*l*. for the necessary expenses of the meeting. In an appropriate speech, the Lord Mayor moved "That this meeting agrees cordially to welcome the British Association to York this year from August 1–8, and in doing so attaches special interest to the fact that the Association began its existence in York seventy-five years ago." The Dean of York seconded this resolution (which was carried unanimously); and in supporting it Dr. Tempest Anderson referred to local connections with the association, the first officials of which included some of the leading members of the Yorkshire Philosophical Society. The local reception committee appointed on Saturday is an unusually strong one: the president is the Lord Archbishop of York; chairman, the Lord Mayor (Mr. R. H. V. Wragge); vice-chairman, Dr. Tempest Anderson; treasurer, Sir J. Sykes Rymer; and secretaries, Mr. R. Percy Dale and Mr. C. E. Elmhirst. Pro-Chancellor A. G. Lupton (University of Leeds) and Prof. W. M. Hicks (University of Sheffield) both spoke at the meeting, and expressed the desire of their universities to assist in making the forthcoming meeting of the association a success.

Sir William Crookes has been elected a corresponding member of the physical section of the Paris Academy of Sciences in succession to the late M. Bichat.

The second congress of the German Röntgen Society will be held at Berlin on April 1–2, under the presidency of Prof. Eberlein.

The largest steel ingot ever made was cast at Manchester on February 1. It weighed no less than 120 tons, and was cast on the Whitworth system of fluid compression. The 120 tons of molten steel were subjected to a pressure of 12,000 tons in order to make the ingot homogeneous and sound throughout.

In order to lessen the smoke and soot nuisance in the town of Helsingfors, the municipal authorities have appointed an engineer, Mr. Ed. Cedercreutz, first to examine and test the boiler and furnace installations in the town, and then to propose suitable means for diminishing the above mentioned source of annoyance.

In honour of the late Prof. Edouard Grimaux, who by reason of his numerous chemical researches, and particularly his contributions on the atomic theory, has taken a high place among French men of science, it is proposed to erect some form of memorial in his native town of Rochefort-sur-Mer. Contributions to the memorial fund are to be addressed to the Mayor of Rochefort, M. E. Marianelli.

The Society of German Portland Cement Manufacturers will hold its twenty-ninth general meeting in Berlin on February 16–17. On the agenda list are the following papers, amongst others:—Report from the society's laboratory, Dr. Framm, of Karlshorst; report of the sea-water commission, Dr. Eng. Rudolf Dyckerhoff, of Amöneburg; report of the committee for examining the change of volume and the time of binding of Portland cement, Dr. Müller, of Rüdersdorf; hydraulic binding appliances, Dr. Goslich, of Züllchow; rotating furnaces, Dr. Michaëlis, sen., of Berlin; the acidity of water and its removal, Mr. H. Wehner, of Kissingen.

On January 28, at Stensjöholm, near Ryssby, in Sweden, the agricultural chemist Prof. Alexander Müller died in his seventy-eighth year. A native-born German, Müller received his early education in Chemnitz and Freiburg, and at the University of Leipzig. In 1851 he was appointed lecturer in chemistry at the Trade School in Chemnitz; from there, in 1856, he was appointed director of the agricultural experimental section of the Landbruks Academy in Stockholm, and consulting agricultural adviser for Sweden and Norway. In this capacity Müller displayed great ingenuity in conducting numerous practical experimental investigations for the welfare of Scandinavian agriculture. The earliest of his published researches dealt chiefly with dairy methods, hygienic questions, and the proper working of various soils. In later years he occupied himself mainly with questions relating to the cleansing of towns, and, indeed, published a number of papers on this subject.

By the death on January 13, at the early age of forty-six, of Prof. A. S. Popow, physical science in general, and Russian science in particular, has lost one of the pioneer band of physicists in the field of wireless telegraphy. After studying at the St. Petersburg University from 1877 to 1883, Prof. Popow was appointed first an assistant, and later professor of physics in the Mining School for Officers at Kronstadt, whilst he also delivered lectures at the Technical High School for the Russian Marine from 1890 to 1901. His zeal for work was extraordinary; although he devoted himself strenuously to experimental work in different branches of electrotechnics, he also found time to superintend the electrical station at Nijni Novgorod, whither he betook himself each summer. His work in 1895 was particularly rich in results, for in the summer of that year he succeeded in signalling over long distances by means of electromagnetic waves, and also invented an apparatus for graphically indicating and recording storms, which in 1896 was introduced into the meteorological observatory of the St. Petersburg Forest Academy, whilst the Parisian firm of Dacretoit constructed a receiving station for wireless telegraphy according to Popow's plans, which have been taken as a model for the installation throughout the Russian Marine. In 1905 Popow was appointed professor of physics at the electrochemical institute in St. Petersburg, and on September 28, 1905, on the declaration of the academic freedom of Russian universities, he was elected director of the institute. Popow's intellectual gifts, his attachment to scientific research, and geniality of intercourse at all times, secured for him the warmest sympathy and respect from both colleagues and students.

In reply to the request made by Prof. S. P. Thompson in last week's Nature (p. 340) for the dates of birth and death of William Nicol, the inventor of the Nicol prism, two correspondents state that Nicol was born about 1768 and died in 1851 at Edinburgh, where he was a teacher of physics. (See the "Century Cyclopedia of Names" published by the *Times*, p. 737.)

It is announced by *Science* that there is a movement being started to present to the City of Philadelphia a statue of Dr. Joseph Leidy. Dr. Leidy, who was born in that city in 1823, and died there in 1891, added much to its scientific eminence, and as president of the Academy of Natural Sciences, professor of human and comparative anatomy and zoology in the University of Pennsylvania, and president of the Wagner Free Institute of Science, accomplished much for these institutions.

The Cairo correspondent of the *Times* states that Mr. T. Barron, the geological surveyor to the Anglo-Sudan Administration, died on January 31 at El Koweit. While in the Survey Department of the Public Works Ministry in Cairo, Mr. Barron rendered excellent services in revising the geology of the country between Cairo and Suez. In 1904 Mr. Barron's services were lent to the Sudan Government, and part of the work with which he was then entrusted included the investigation of the lignite deposits of Tchelga, in north-west Abyssinia. He eventually joined the Sudan service.

Dr. C. G. Seligmann, Hunterian professor for 1906, delivered the first of his three lectures on Monday in the theatre of the Royal College of Surgeons, and took as his subject the "Physical Anthropology and Ethnology of British New Guinea." After directing attention to the general features of New Guinea, Dr. Seligmann proceeded to classify the natives of British New Guinea into four main stocks, Papuo-Melanesian in the south-east, Motuan around Port Moresby, Eastern Papuan in the hinterland or mountainous region, and West Papuan in the large western area, much of which is still unknown. The lecturer pointed out that there were linguistic and other resemblances between his Papuo-Melanesian stock and the island Melanesians, particularly those of the Solomon Islands. There is an area of brachycephaly on the west

of the Papuan Gulf for which it is very difficult to account; members of this stock seem to form part of the population south of the Fly River. The average stature rises in proceeding from the centre of the Gulf eastwards. There is no reason to suspect Australian influence, even in the Torres Straits Islands.—The lectures are open to the public; the second was given yesterday, and the concluding one will be delivered to-morrow (Friday) at five o'clock.

PROF. S. H. REYNOLDS, University College, Bristol, informs us that the rock fall at Cheddar on the night of Sunday, February 4, is not a matter of any very great moment, though much has been made of it in the papers. The point at which it took place is a quarry on the northern or dip slope side of the gorge, which here follows the strike of the rocks. The fallen rock detached itself from the quarry face along the bend of a master joint, and estimates of its amount vary from 70,000 tons to 500,000 tons; but an experienced quarry owner has assured Prof. Reynolds that 20,000 tons is about the amount of the fall. Though this may seem a very large amount, the fall is entirely confined to the face of the quarry, and the general features and beauty of the gorge are absolutely unaffected by it.

FIG. 1.—The recent rock-fall at Cheddar.

IN the annual report on British New Guinea for 1903, Sir F. Winter described a people on the Musa River, named Agaiambo; according to the newspaper reports of the period they are web-footed dwarfs; subsequent information went to show that they had been wiped out by a hostile tribe. The latest report, for 1904–5, shows that this latter item was incorrect, for ten members of the tribe have been measured by Captain Barton, and their photographs sent to Sydney. Unfortunately, much of the latest information is contradictory of the earlier report; the Agaiambo are stated to kneel in their canoes or sit on their heels, and to this circumstance their physical peculiarities are attributed; but Sir F. Winter says that they stand. Moreover, it is difficult to see how sitting on the heel could produce, as alleged, a protrusion of the heel. There is no evidence to show that the tribe is web-footed; they are not dwarfs; the man seen by Sir F. Winter stood as high as an ordinary native; what was peculiar about him was that the lower extremities were badly developed, so that his hips were 3 inches lower than those of the ordinary native. This feature seems to be borne out by the later evidence. There is no reason at present to suppose that they are of different stock from their neighbours; they are said to speak the same language as the Barigi, with whom they barter produce.

IN a paper on library aids to mathematical research, published in the *Proceedings of the Royal Society of Edinburgh*, Dr. Thomas Muir has touched upon a subject of ever-growing importance that has not yet received the systematic attention in this country which it needs. It deals with the requirements of the scientific investigator classed under the two general main categories of books and books about books. The paper is confined to the single subject of mathematics, with reference to Scotland in particular, but, as Dr. Muir remarks, "there can be no doubt, however, that other subjects are in as bad a plight, and that the whole question of library aid is worth serious and prompt attention from all scientific men." Commencing with "books about books," or summaries of existing literature, and excluding the "Bibliotheca Mathematica," which is different in scope, Dr. Muir finds that the mathematician is adequately provided for as regards past literature by Poggendorff's "Handwörterbuch" and the Royal Society catalogues, and as regards current literature by the "Jahrbuch über die Fortschritte," the Amsterdam "Revue semestrelle," and the "International Catalogue of Scientific Literature." But when it comes to the books themselves, the present state of affairs is eminently unsatisfactory. Confining his attention to the sixty-seven serials, mainly mathematical, included in the list published in the "International Catalogue, A" for 1903, Dr. Muir tabulates the state of affairs in the libraries of the University and Royal Society of Edinburgh and the University and Philosophical Society of Glasgow. He finds that only thirty-four of the sixty-seven periodicals are to be found in the combined libraries of southern Scotland, and many sets are incomplete, but that a considerable duplication exists in the libraries in question. Austrian mathematics is unrepresented. An annual expenditure of 100*l.* would suffice to purchase and preserve all the serials on the list, but even without any expenditure whatever the whole object could be attained by cooperation between the several libraries and gradual elimination of the cases of duplication. Dr. Muir considers that mathematical research at present can only be pursued in Scotland with difficulty and uncertainty, and that research in mathematical history is practically an impossibility. What Dr. Muir says regarding Scotland applies with still more force to libraries elsewhere. If he had extended his study, for example, to Wales, he would have found three separate libraries in the three university colleges each with only some 10*l.* or so per annum for purchase and binding of books and periodicals.

THE opening article in the January number of *Himmel und Erde* is devoted to the discussion of the question whether the attributes of organisms can be due to physical causes. In concluding this article, the author, Dr. V. Franz, of Breslau, points out that, although a physical origin of life is highly probable, its demonstration is a matter of almost insuperable difficulty.

IN the January issue of the *Museums Journal*, Mr. J. Minto discusses the relation of provincial museums to national institutions. After pointing out that local museums cannot at the present day grow with the requisite rapidity and properly discharge their educational functions if dependent solely upon donations, the author expresses himself as follows:—"It will take years to do away with

the idea of museums still entertained by many members of committees, as store-houses of curiosities, and to understand that museums must form part of the educational machinery of the nation."

WE reproduce from an article on the Florida Keys, published in the *National Geographic Magazine* for February, an exceedingly interesting photograph of an alligator's nest, showing a large number of eggs, from some of which young alligators have been hatched. In common

FIG. 1.—An alligator's n st, with newly-hatched alligators, in Fl rida. From the *National Geographic Magazine*.

with the caimans of Central and South America, the Mississippi alligator lays a number of eggs amid brushwood, which are carefully covered over with débris, and guarded during the period of incubation by the parent. In due course the young alligators are hatched, and soon make their way to the water, the nest, at least in the case of some of the Brazilian caimans, being opened by the female parent in order to facilitate the escape of her progeny.

IN an instructive article entitled "Saving California's Fruit Crops," published in the *Century Magazine* for February, the author, Mr. W. S. Harwood, dwells on the important services Mr. Compere has rendered to fruit-growers in America, and thus throughout the world, by his efforts to discover insects which will hold in check some of the most injurious insect fruit-pests. Mr. Compere's idea is that every injurious insect has an enemy in some part of the world, if only it can be found. He discovered, for instance, in Spain, a region where the codling-moth lives, but where the ravages of the worm to which its eggs give birth were slight. Investigation showed that this was due to an ichneumon-fly, by which the pest was kept in check. Naturally it was assumed that what held good for Spain would also be efficient in California, and a number of ichneumon-pupæ were accordingly packed and dispatched to the States. When the flies hatched they at once set to work on the codling-moth caterpillars, with the result that a swarm of young ichneumons has been produced, and it is hoped that in course of time the codling-moth pest may become a thing of the past. Another plan is to send a small tree of the species affected by a particular pest to the country where the enemy lives, whence it is returned to its native home provided with a stock of destroyers.

To the *American Naturalist* for January Lieut.-Colonel C. D. Durnford contributes an article (also published synchronously in this country in the *Annals and Magazine of Natural History*) on the flight of flying-fishes. In this it is maintained that the ordinary "aëroplane theory" of the flight of these fishes is based on an absolute mechanical impossibility, and that the real explanation is to be found in an intensely rapid vibration of the wing-like pectoral fins—a vibration which is revealed to the eye when the movement slows down as the fish touches the crest of a wave. In another article in the same journal Messrs. Dexler and Freund furnish some interesting information with regard to the mode of life of the dugong, noting also the various methods employed in the capture of these animals in Queensland. It is confirmed that dugongs do not voluntarily leave the water, while it is suggested that they seldom enter brackish, and are incapable of living in fresh water. Much interest attaches to the existence of a slimy coating for the protection of the eye, a similar coating also occurring in whales, although in the latter instance it is of an oily nature, in order to prevent its being too easily washed away by the sea-water.

IN *Macmillan's Magazine* for February, Mr. H. L. Puxley describes the unhygienic conditions which largely obtain in the production and distribution of milk, and suggests the precautions which should be taken to ensure a wholesome milk supply.

MESSRS. SANDERS AND CROWHURST, Shaftesbury Avenue, W., have submitted for our inspection a series of excellent lantern slides, and an album, entitled "Wild Birds at Home," of sixty beautiful reproductions of photographs taken with the "Birdland" camera, which has been made specially for natural history photography. A comparison of these life-like pictures—which are faithful representations of the actual environments of the birds depicted, untouched in any way by engravers—with the woodcuts which comparatively few years ago were the only illustrations available for works on natural history will demonstrate vividly the astonishing advances in pictorial illus-

FIG. 1.—Gannets on the wing. From a photograph taken with the "Birdland" Camera.

tration made possible by instruments like the "Birdland" camera in the hands of patient observers. Photographs of this high excellence both encourage and assist the study of animal life.

THE *Journal of Hygiene* for January (vi., No. 1) contains papers by Prof. Muir and Mr. Browning on anti-immune bodies and complementoids and on the action of comple-

ment as agglutinin, by Mr. MacConkey on a method for hastening the liquefaction of gelatin by the *B. clouceae*, by Dr. Boycott on the bacteriology of para-typhoid fever, and by Dr. Haldane on a portable apparatus for gas analysis. Dr. Sandilands writes on epidemic diarrhœa and the bacterial content of food, suggesting that flies may be the active agents in conveying this disease, no mention, however, being made of Dr. Nash's previous work in this direction. Prof. Ronald Ross directs attention to the occurrence of flagellated protozoan parasites in the mosquito (*C. fatigans*), which he suggests may invalidate Schaudinn's work on the development of the hæmosporidian *Halteridium danilewskyi* in this insect. Dr. Hamilton Wright also contributes a reply to Dr. Travers's criticism of preventive measures against beri-beri, which appeared in a former number of the Journal.

A SELECT list of works prepared at the Royal Botanic Gardens, Kew, by members of the staff, or in collaboration with them, has just been published as No. 1 of the *Kew Bulletin*, 1905. The list is extensive, as it goes so far back as 1859, when Grisebach's "Flora of the British West Indies" began to appear, and it includes Dr. Watt's "Dictionary of Economic Products of India" and the *Annals of Botany*. It is to be hoped that this number is a precursor to the resuscitation of the Bulletin.

FROM the Department of Agriculture, Nairobi, a leaflet, No. 10, has been issued on the insect and fungoid pests reported during the year 1904-5. The larvæ of a moth, *Spodoptera exempta*, destroyed the vegetation near Nairobi; a ladybird, *Epilachna similis*, is mentioned as doing great damage to maize and wheat; and several beetles and other insects were observed. Amongst fungi, wheat-rust proved fatal to the prospects of the wheat crop, dwarf beans suffered from rust and anthracnose, and the crop of chick-pea, *Cicer arietinum*, was completely destroyed by a *uredo*-fungus.

THE historic quotation connected with Darwin's examination of the primrose might well be repeated with reference to a posthumous paper on the oxlip by the late Prof. Errera, edited by Miss J. Wéry for the *Receuil de l'Institut botanique*, Brussels (vol. vi.). The paper furnishes a good illustration of Prof. Errera's talent for drawing deductions from simple experiments or observations. It was found that although the number of long-styled and short-styled plants was about equal, a bunch of flowers collected at random nearly always contained more of the long-styled, this being due to the slightly larger size of the flowers; the balance is maintained by the direct fertilisation of a larger number of short-styled flowers.

WE have received the report of the Meteorological Service of Canada for the year 1903. At the chief stations observations are taken day and night at equal intervals of time not exceeding four hours; at other stations they are taken three times daily, except in the case of those recording only rainfall and the general state of the weather. For the purpose of weather forecasts the country is divided into ten districts; the general success of fully or partially verified predictions amounted to 86 per cent. The results for the numerous stations are very carefully prepared, and include observations in Newfoundland, Labrador, and Bermuda, together with a chronicle of the chief characteristics of the weather in each month. Maximum shade temperatures of 99° were registered at Alberni, British Columbia, in June, Melfort, N.W. Territories, and St. Alban's, Manitoba, in July; minimum, −67°, at Good Hope, N.W. Territories, in February.

THE *U.S. Monthly Weather Review* for September last contains an account of the Japanese meteorological service in Korea and Manchuria. At the beginning of the Russo-Japanese war, Prof. Wada, who had been connected with the meteorological service of Japan since 1879, was entrusted by the Japanese Government with the organisation of a similar system in Korea and Manchuria, and is now completing the work as chief of that service; up to the present time fourteen stations have been established. A first-class observatory has been established at Chemulpo; the other stations, including Mukden, Fusan, and Port Arthur, are mostly of the second order. All the coast stations issue daily weather predictions, which are made known by means of flags; the central observatory issues storm warnings when an atmospheric disturbance is expected on or near the coasts of Korea and Manchuria, and day and night signals are immediately displayed at all stations.

IN view of the fact that acetylene gas is used in Germany to a very large extent, it is proposed to form a guild of acetylene apparatus owners for the purpose of collecting, arranging, and distributing information on methods of preparation and storing and on the uses of acetylene.

IT has long been known that the province of the Pechora is rich in mineral treasures. Quite recently a party of Russian and Belgian engineers examined the basin of the Ussa, and made rich finds of naphtha and copper ores. In fact, it is stated that the quantity of naphtha to be obtained from surface deposits in the Pechora district exceeds that present in the Caucasus, and is of a better quality, whilst the tonnage of easily workable copper ores is given as many millions. But for the working of these treasure-fields a large sum of money will be required, inasmuch as even the most primitive roads and methods of easy communication are practically unknown; also the population, and consequently the supply of labour, is extremely small. However, it is reported from St. Petersburg that energetic efforts are being made to obtain the necessary capital.

IN the *Lancet* for December 16, 1905, Dr. P. W. Latham describes a new method of directly transforming α-benzoyl-amino-*p*-hydroxycinnamic acid into tyrosine, by heating it with potassium cyanide, which acts as a reducing agent, and subsequently boiling the product with aqueous barium hydroxide. A theory, based on these observations, is advanced as to the method of formation of tyrosine in the animal body.

IN a note published in the *Annalen der Physik* (series 4, vol. xviii., p. 860), Prof. B. Walter recommends the use of a material called "picein," manufactured by the New York-Hamburg Indiarubber Company, as a cement for joining together pieces of physical apparatus; it is preferable to sealing-wax on account of the ease with which it can be worked, and the fact that it does not become brittle. As it is insoluble in water and alcohol, it can be used in contact with solutions prepared with these solvents, for example in absorption cells.

WE have received a reprint of a memoir by Prof. Augusto Righi, published in the *Memorie* of the Royal Academy of Sciences of Bologna (series vi., vol. ii., p. 151), in which full details are given of the method used in ascertaining the connection existing between the atomic weight of an element and the amount of secondary radiation it emits when subjected to the β and γ rays of radium; the results have already been noticed in NATURE (vol. lxxii. p. 350).

IN the *Atti dei Lincei* (series 5, vol. xiv., ii., 207) Prof. A. Righi describes a number of experiments which were made with the purpose of ascertaining the influence of the rays of radium on the resistance of certain solid and liquid dielectrics. A marked increase in the conductivity under the influence of the rays was observed in the case of liquid vaseline and olive oil, but with benzene, petroleum ether, and carbon bisulphide a much smaller effect was found. When solid colophony was subjected to the action of the rays, a change of conductivity could not be detected.

A WORK upon steam turbines, by Messrs. T. Stevens and H. M. Hobart, giving the most recent results in practice and having a concise account of the latest types, will be issued by Messrs. Whittaker and Co. in March.

MESSRS. SWAN SONNENSCHEIN AND CO., LTD., have now published the "Public Schools Year-book" for 1906, being the seventeenth issue of this important annual. Among other useful chapters which the volume contains, in addition to full particulars of 117 public schools, those dealing with engineering, medicine, agriculture, and horticulture as professions are of particular value to parents desiring occupations for their boys.

MR. FRANCIS HODGSON has published the third volume of the second series of the *Proceedings of the London Mathematical Society*. The volume runs to 482 pages, and includes papers read before the society during the period December 8, 1904, to November 9, 1905. As the papers read at meetings of the society are briefly described in our "Societies and Academies" columns, there is no necessity for a detailed statement of the contents of the volume, though it may be added that, in addition to the papers, the volume includes records of the proceedings at meetings and an obituary notice of the late Mr. Robert Tucker by Prof. M. J. M. Hill, F.R.S.

OUR ASTRONOMICAL COLUMN.

COMET 1905*c* (GIACOBINI).—Herr A. Wedemeyer gives a continuation of his daily ephemeris for comet 1905*c* in No. 4074 of the *Astronomische Nachrichten*. The following is an extract therefrom:—

Ephemeris 12h. M.T. Berlin.

1906	α (true) h. m. s.	δ (true) ° ′	log *r*	log Δ	Brightness
Feb 18	0 49 32	−13 26	9·9192	0·1123	2·91
20	1 2 3	−11 55	9·9424	0·1237	2·48
22	1 13 48	−10 27	9·9640	0·1355	2·13
24	1 24 45	− 9 2	9·9843	0·1477	1·83
26	1 35 0	− 7 41	0·0034	0·1602	1·58
28	1 44 37	− 6 24	0·0214	0·1728	1·38

Brightness at time of discovery = 1·0.

It will be noticed that the comet has rapidly decreased in brightness, and, as its magnitude when discovered was only about 10·0, has become a more difficult object. On February 18 it will set about $2\frac{1}{2}$ hours after sunset in the south-west.

COMET 1906*a* (BROOKS).—Several observations of comet 1906*a* are recorded in No. 4073 of the *Astronomische Nachrichten*, in which also appear a set of elements and an ephemeris calculated by Herr M. Ebell.

The magnitude of the comet on January 28–31 was about 10·0, and Prof. Hartwig, observing with the Bamberg heliometer on the latter date, recorded that the comet was round, had no tail, and had a central nucleus which appeared to be about one magnitude fainter than a 9·3 magnitude star.

The latter part of Herr Ebell's ephemeris is given below:—

12h. M.T. Berlin.

1906	α (true) h. m. s.	δ (true)	log *r*	log Δ	Brightness
Feb. 16	12 4 44	+84 35	0·1909	9·9742	0·99
17	10 35 41	+84 48			
18	9 13 22	+84 15	0·1955	9·9817	0·94
19	8 12 51	+83 8			
20	7 32 10	+81 43	0·2001	9·9912	0·88

Although near to the pole, the comet is not an easy object, owing to its small magnitude, which is now decreasing.

OBSERVATIONS OF EROS.—The results of a number of observations of Eros, made at the Arcetri Observatory between July 26 and August 25, 1905, appear in No. 4073 of the *Astronomische Nachrichten*.

Variations in the magnitude of the asteroid were observed as follows:—July 28, mag. = 11·4; August 7, mag. = 10·9; August 23, mag. = 12·0.

Comets 1905*b* and 1905*c* were also observed at Arcetri, and the results are given in the same journal.

CATALOGUE OF STARS WITHIN TWO DEGREES OF THE NORTH POLE.—Publication No. 2 of the Vassar College Observatory is devoted to a catalogue of 408 stars all of which are within 2° of the North Pole. The coordinates and magnitudes have been determined from eight plates taken by Prof. Donner, of the Helsingfors (Finland) Observatory, by Dr. Caroline E. Furness. A previous publication (No. 1) dealt similarly with the stars situated within 1° of the pole, and to this the present volume forms a sequel. The positions are given for 1888·0, and in cases where the star is common to both, references are given to the B.D.M. and Carrington catalogues. The present work is published by the Carnegie Institution, and forms No. 45 in the publications of that body.

THE FIRE NEAR MOUNT WILSON OBSERVATORY.—Writing to *Popular Astronomy*, No. 2, vol. xiv., Prof. Hale corrects the recent report concerning the forest fire on Mount Lowe, and states that, as the fire did not come within several miles of the Solar Observatory, the observers there were never in any fear that the buildings or instruments might be injured.

THE INCREASING PERIOD OF β LYRÆ.—In an article published in No. 367 of the *Observatory*, Dr. Alex. W. Roberts makes an interesting suggestion concerning the diminishing rate of increase in the period of β Lyræ.

Having discussed a number of previous observations, he has deduced a formula which gives the period of this variable at any date, the epoch being 1900·0. The suggested cause is that in β Lyræ we have a binary in which the component stars are slowly receding from each other under tidal forces, and if this is so it provides direct evidence in support of Prof. Darwin's theory regarding the evolution of planetary and stellar systems.

THE UNITED STATES NAVAL OBSERVATORY.—Rear-Admiral Chester's report of the operations of the United States Naval Observatory for the fiscal year ending June 30, 1905, shows that the staff is again to be congratulated on the amount of work performed. Nearly 950 observations, including 218 of Saturn's satellites, were made with the equatorial, and 9179 observations were made with the meridian instruments; the latter included nearly 4000 observations of Gill's "zodiacal stars" and an equal number of "standard stars."

The A.G. Zone Catalogue of the stars between −13° 50′ and −18° 10′ is nearing completion; all the stars have been observed, and most of the observations have been reduced to 1900·0.

With the photoheliograph, photographs of the sun were obtained on 166 days, and showed spots and faculæ on the solar disc on 162 days. Whilst engaged upon this work, Mr. G. H. Peters made some valuable observations regarding the focal variation due to temperature. A new triple lens of $7\frac{1}{2}$ inches aperture and 65 feet focal length, giving a solar image of about 7 inches diameter, has been procured, and was to be used for solar photography after its employment on the 1905 eclipse expedition to Spain.

The branch observatory at Tutuila, Samoa, was, on the date of the report, rapidly approaching completion.

RECENT REPORTS OF GEOLOGICAL SURVEYS.[1]

Cleavage.

THE subject of rock cleavage is one of perennial interest; only a short time ago were Dr. Becker's views noticed in these columns, views founded upon experiment and analysis. Now, Dr. Leith (1) lays before us his reading of the same problems after attacking them by the way of micro-sections and field observations. The author makes the term "rock cleavage" very comprehensive; he recognises among cleavable rocks two broad divisions, which he calls respectively protoclase, or original cleavage rock, and metaclase, or secondary cleavage rock. The former class includes such structures as bedding in sediments and flow structure in lavas; the latter class is considered under the heads "fracture cleavage" and "flow cleavage." Fracture cleavage is conditioned by the existence of incipient or cemented and welded parallel fractures, and is independent of the parallel arrangement of the mineral constituents. Flow cleavage is conditioned solely by a parallel arrangement of the minerals. The one is a phenomenon of the zone of fracture, the other of the zone of flowage in the lithosphere. Fracture cleavage is made to include, wholly or in part, those structures that have been variously described as close-joint-cleavage, false

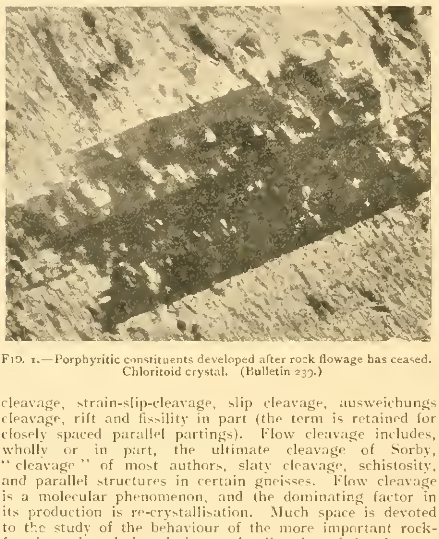

FIG. 1.—Porphyritic constituents developed after rock flowage has ceased. Chloritoid crystal. (Bulletin 239.)

cleavage, strain-slip-cleavage, slip cleavage, ausweichungs cleavage, rift and fissility in part (the term is retained for closely spaced parallel partings). Flow cleavage includes, wholly or in part, the ultimate cleavage of Sorby, "cleavage" of most authors, slaty cleavage, schistosity, and parallel structures in certain gneisses. Flow cleavage is a molecular phenomenon, and the dominating factor in its production is re-crystallisation. Much space is devoted to the study of the behaviour of the more important rock-forming minerals in relation to the direction of the cleavage in rocks, and many thin slices have been examined to determine how far there existed a parallelism between the cleavage of the rock and dimensional and vector properties of given mineral species.

The bulletin is evidently the result of a great deal of work, and contains a clear statement of the author's views; the illustrations are excellent, and it must be read by all interested in the subject, but it cannot be said greatly to advance our knowledge.

The Geology of Cements.

Several reports have appeared from time to time dealing with the raw cement materials of individual States; in Bulletin No. 243, E. C. Eckel (2) summarises the available information for the United States as a whole. "The object has been to treat the subject from the geological rather than from the technical standpoint, although the technology of the cement manufacture is also discussed with sufficient fulness for the purpose of the report." While mainly a compilation, and bearing the impress of composite authorship, there is in this volume an air of freshness about the facts and of uniformity about their presentation which is doubtless due to the circumstance that Mr. Eckel personally visited every district in which cement is being produced, and examined nearly every plant in operation. Nor were the undeveloped deposits of cement material neglected.

The bulk of the report is devoted to Portland cement materials in the several States; the geological characters and relationships of the limestones, clays, and natural cement rock are clearly explained, abundant analyses are shown, and the peculiar local conditions of transport and fuel, as well as the available markets, are briefly discussed. The cement materials are derived from rocks of the most diverse geological age, ranging from Cambrian up to recent marls and alluvial silts. Short sections are given to the "natural" cement resources and to the Puzzolan cements. We noticed in the section on the grinding of raw materials no reference to the influence of the degree of fineness upon the temperature required for a suitable clinker.

General Geology.

The average British geologist, if his range of vision is not quite limited by the importance of the exposure in his own back garden, if he can momentarily turn from pebble-picking and the unravelling of zones, may enjoy by following Prof. Russell across central Oregon, a pleasant and profitable, if somewhat tantalising, hour. The region included in this preliminary report (3) comprises the country between the Snake River on the east and the Cascade Range on the west, and thus takes in the extreme northern part of the Great Basin.

The predominant rocks of central Oregon are volcanic; an older series of rhyolites and andesites is succeeded by a younger series of basaltic rocks, which are again followed in the Pauline Lake district by andesitic outbursts. The oldest of the rocks dates from early Tertiary times; the youngest may be only a few centuries old.

The sedimentary rocks are represented by soft clays, sands and volcanic dust of Tertiary age. The most conspicuous elevations in central Oregon are of volcanic origin; many are old worn-down craters and peaks, but young volcanoes, particularly as the Cascades are approached, are exceedingly abundant. "Their cones, so recent in numerous instances that erosion has not yet broken their crater rims, are so numerous that 50 or more may frequently be counted in a single view, while a change of a few miles in the position of the observer brings perhaps as many more within the range of vision."

Many interesting features in the water supply and drainage of the country are described in these pages, but none exceeds in interest the fascinating story of the Deschutes River, about the point where it is joined by its tributary the Crooked River. First we find that the Deschutes in Tertiary times had eroded a great valley twenty to thirty miles wide in parts; then most of this valley was filled to a depth of more than 700 feet by water-borne volcanic dust and lapilli with a little sand and clay; this was followed by a sheet of basalt some 80 feet thick. Displaced in this way from their old courses, the Deschutes and its tributaries cut fresh channels and made canyons in the new material 800 feet deep and about one mile wide, until

once more an outburst of basaltic lava filled up the canyons to a depth of at least 500 feet. Still in their old courses, but displaced from their channels, the streams had again to commence re-excavation. At the present time they have cut through more than 500 feet of the hard basalt without reaching its bottom. The two periods of canyon cutting probably belong to the "Sierran" epoch of Le Conte.

Hot springs, desert conditions, glaciation, and the influence of domestic animals upon river erosion form the subjects of notes. The illustrations are beautiful, and helpful to the text.

FIG. 2.—View of double-crested moraine on south-side of Hayden Glacier, looking west. (Bulletin 252.)

The region about the northern limit of the Cascade Range was traversed by Messrs. G. O. Smith and F. C. Calkins (4) in a rapid reconnaissance. The older rocks encountered are grouped together as pre-Cretaceous, comprising (1) old-looking schists along the Columbia River and lower Okanogan Valley; (2) supposed Carboniferous sediments with volcanics in the more northern part of the Okanogan Valley; (3) strata similar to the last mentioned exposed in the base of the upper Skagit River; (4) some old sediments and a great volcanic mass near Hamilton; and (5) a great assemblage of strata ranging from Palæozoic to Jurassic lying to the west and north of Mt. Baker.

An extensive development of the Cretaceous is indicated from the Hozomeen Range on the west to the Similkameen Range on the east; the name "Pasayten formation" is proposed for this in place of Prof. Russell's term Similkameen. Sandstones and shales predominate; contemporaneous igneous rocks appear to be absent. Tertiary sediments occupy a much smaller area than do the Cretaceous, but volcanic rocks, presumably of this age, are of some importance. Later formations are represented by glacial and river gravels, and by the andesitic lavas of Mt. Baker.

As compared with their immense importance in the southern Cascades, the part played by volcanic rocks in the boundary section appears very subordinate. Plutonic rocks are greatly developed, the prevailing type being a "grano-diorite." The volcanic rocks range from soda-rhyolite, dacite, acid and basic andesites, to basalt. The dyke rocks include a soda-syenite from south of Bighorn Peak, and a diorite (?) in which apatite occurs in broad, irregular plates as one of the last products of crystallisation. The authors conclude that volcanic and plutonic rocks alike may have been derived from a homogeneous magma, low in alkalies, with soda predominating over potash; hence they may belong to the same province as the rocks of the southern Cascades and the Sierra Nevada.

Dr. Dale has written a short account of the stratigraphy of a strip of the Hudson Valley (5) between the Hudson River on the west and the Rensselaer Plateau and the Taconic Range on the east. The difficulties in the way of delimiting the age and relations of the several formations are the rarity and bad preservation of the fossils, the repeated minor overfolding, and the prevalence of Glacial drift. An excellent map accompanies the paper on the scale of 1 inch to the mile; fossil localities and good outcrops are clearly indicated by a system of coloured spots—a plan worthy of imitation.

The formations represented are Lower Cambrian, Beekmantown shale with Dictyonema and Clonagraptus, the Hudson shale and Hudson schist (Ordovician = Trenton), and the Silurian Rensselaer Grit = Oneida, Medina.

Three crustal movements are recognised in the area:—(*a*) at the close of the Lower Cambrian, Upper and Middle Cambrian are missing; (*b*) the Taconic or Green Mountain movement which folded the Ordovician beds; (*c*) a post-Devonian or Carboniferous movement which folded the Silurian Grit of the Rensselaer Plateau. Minor oscillations are indicated by conglomerates which occur in the Lower Cambrian, in the Hudson shale, and in the Rensselaer Grit.

Although only ten years had elapsed since Cross and Penrose made a careful study of the Cripple Creek district, the people of Colorado asked for a re-survey on account of the great development of underground working in the interval; this re-survey has been undertaken by Messrs. Lindgren and Ransome, who have now issued a report of progress (6) in advance of the laboratory examinations.

FIG. 3.—View in Opal Canyon, Crooked River, Crook County, showing basalt of inner canyon in contact with stratified beds of outer canyon. (Bulletin 252.)

The oldest rocks in the district are the muscovite and fibrolite schists; these are closely associated with fine-grained granitic gneiss. Both gneiss and schist are cut by a reddish granite. A second type of granite is the coarsely porphyritic Pikes Peak type. As a result of the recent work, the views of Cross upon the rocks erupted

from the Cripple Creek volcanic centre are somewhat modified; the various rock types recognised by him are shown to be linked by intermediate forms; they are clearly all divergent eruptive facies of one general magma, characterised by containing from 9 per cent. to 15 per cent. of potash and soda, the soda being always somewhat higher than the potash; no true andesite is recognised. Most of the ore has come from the central area of phonolitic breccia.

The bulk of the telluride ore-bodies is in fissure veins, either simple or complex, being closely spaced and linked together, constituting what is called a "sheeted zone." The fissures radiate from a point to the north of the area; they are uniformly narrow, therefore the amount of gangue and ore is comparatively small. Quartz, fluorspar, and other minerals usually line the walls of the fissures; the rich tellurides are generally the last minerals to form. The authors consider that the unoxidised ore deposits represent the product of one period of general mineralisation not appreciably modified by any secondary enrichment. The last exhalation of the Cripple Creek volcano seems to be a mixture of nitrogen with about 20 per cent. of carbon dioxide and a small amount of oxygen. The gas increases in quantity with the depth, and in some cases interferes seriously with mining operations.

An interesting description of the petrography of the Highwood Mountains of Montana (7) is given by Prof. Pirsson. This region is occupied by a greatly eroded group of volcanoes which were in activity at some time subsequent to the Lower Cretaceous; several necks (stocks) are exposed, and now stand up as prominent peaks. Highwood Peak, the highest point in the group, is composed of syenite (pulaskose) and monzonite (shoshonose); in East Peak the rock is a basic leucite syenite. The Shonkin stock is shown to consist of Missourite, passing by intermediate stages into shonkinite. The Arnoux stock is important as the source of a new variety, *Fergusite* (fergusose), a rather coarse-grained, pseudo-leucitic augite rock, consisting of orthoclase, nepheline, and diopside; it appears to bear a similar relation to the leucitites that missourite does to the leucite basalts. In describing the petrographic characters of the necks, dykes, and extrusive flows, the new nomenclature is used concurrently with the old, so that the conservative reader need not be dismayed by "Trachyphyro-Highwoodose," "grano-shoshonose," or what not. The author concludes with some suggestive remarks on magmatic differentiation.

The annual report of the United States Geological Survey (8) is, as usual, a record of excellent organisation and of abundant energy in all departments.

The twenty-ninth annual report on the geology and natural resources of Indiana (9) contains a monograph of some 650 pages, by Prof. Blatchley, on the clays and clay industries of the State, the reports of the inspectors of mines and natural gas, a paper on the utilisation of convict labour in making road material, an account of the petroleum industry in Indiana in 1904, and a paper on the insect galls of Indiana.

The section on clays is very much like similar reports with which we are becoming daily more familiar; it is an excellent report of its kind. It describes in detail the clay resources of each county, with geological information and analyses; suggestions are given as to available clays and shales that are as yet unworked, and advice is given as to the best way of dealing with them. The use of bricks for road-making is strongly advocated, and the full specifications for the construction of brick pavements in the city of Terre Haute are given; these may prove of interest to those in this country who favour this type of road—the brick roads in Terre Haute have given great satisfaction. The report is illustrated with photographs and maps, and with full statistics of the various branches of the clay industry.

The paper on insect galls, by Dr. Cook, is little more than a catalogue of the galls known in the State. It is provided with a simple introduction to the subject and a bibliography, and with numerous outline sketches and photographs. It should be appreciated in the State. We are not aware that the papers mentioned above are issued separately; if this is not the case it seems unfortunate, for they appeal to such divergent interests.

The summary report of the Geological Survey of Canada (10) for 1904 indicates considerable activity in all quarters of the Dominion. A striking illustration of the usefulness of the survey lies in the discovery of a coal seam 10 feet thick in a bore-hole 2340 feet deep in Cumberland, Nova Scotia. This bore-hole was sunk through a thick cover of unproductive rocks at the suggestion of Mr. Hugh Fletcher, of the Geological Survey staff, after he had worked out the structural geology of the district.

In the Purcell Range, Dr. Daly records an enormous sill of hornblende-gabbro, 2500 feet thick; this he calls the "Moyie sill," from its occurrence at a point where the Moyie River crosses the international boundary. This great mass of basic rock has been thrust into the pre-Cambrian Kitchener quartzite, with the result that its upper portion, some 200 feet thick, has been converted into an acid biotite-granite by assimilation of the siliceous sediment. This has come about principally through the agency of "gravitational differentiation" following the shattering of the quartzite by the heated contact.

Prospecting for iron by means of the magnetometer (Thalen-Tiberg form), an innovation in Canada, seems to have had good results in Charlotte County, New Brunswick. Dr. Barlow contributes some notes on the occurrence of corundum in the intrusive complex of Robillard Mountain at Craigmont. The corundiferous rocks are of syenitic or gabbroid type; scapolite and nepheline often accompany or replace the prevailing felspars. Some of the syenite contains as much as 34 per cent. of corundum.

J. A. H.

THE PERIODICITIES OF SUN-SPOTS.[1]

EVERYBODY knows how to interpret the curve by means of which the intensity of radiation of a body is expressed in terms of the wave-length or frequency, and everybody recognises the utility of such a curve. It allows us at once to distinguish between the line spectrum and the spectrum of bands or the continuous spectrum, and brings out regularities which would be difficult to recognise in the original disturbance. In practice we employ the spectroscope to give us the data from which the curve of intensities is constructed. But what the spectroscope can do for a luminous disturbance, calculation can do for any quantity which fluctuates about a mean value. We are able, therefore, to construct in every case a curve which in all respects is analogous to the graph which connects the period and intensity of radiation. This curve I call the periodograph, and refer to the diagram embodying the curve as the periodogram. There is a periodogram of rainfall or barometric change, and these curves would, in my opinion, if constructed for different localities, yield us most important and characteristic information about climate.

During the last three years I have been occupied in calculating the periodogram of sun-spot variability. The results have been communicated to the Royal Society, and the following is a summary of abstracts which are published in the *Proceedings* of that society. The first paper deals with a detailed examination proving that the process I employ furnishes an analysis which is identical with the experimental spectrum analysis supplied by the grating. In the second paper the method is applied to the statistics of sun-spots.

The data used were Wolf and Wolfer's sun-spot numbers, which give us sufficient information from the year 1749 to the present time. I have in addition used, wherever possible, the measurements of areas which for each synodic revolution of the sun have been collected by the Solar Physics Committee of the British Board of Education from the year 1832 onwards, and the areas measured from photographs at the Greenwich Observatory for each day of the year since January 1, 1883.

The whole of the observations were treated collectively, but the complete interval of 150 years was also divided into two nearly equal portions, which were separately examined. At first sight, the results obtained by a com-

[1] Abstract of two papers, entitled, (1) "The Periodogram and its Optical Applications"; (2) "The Periodicity of Sun-spots." Read before the Royal Society on December 7, 1905.

parison of the two intervals of 75 years were exceedingly puzzling. While the observations beginning with about 1826 showed a nearly homogeneous variation of 11·125 years, this period seemed almost entirely absent between 1749 and 1826. Its place was during that interval taken by two important groups of periodicities, one of which had a periodic time of about 9·25 years, while the second had an average period of 13·75 years. The latter period was represented more nearly by what in spectroscopy is called a "band," extending from 13·25 to 14·25 years, but some of this want of definiteness may be due to the deficiency in observational data. For some time I was inclined to draw the conclusion that such periodicities as we observe are comparatively short lived, and replaced by a number of others which in their turn die out. A more detailed investigation, however, convinced me that the periodicities are, as regards the interval of time elapsing between successive maxima, extremely regular, occurring with what may prove to be astronomical accuracy. The key of the solution is, I believe, to be found in the overlapping of a number of periods, all of which are regular as regards time, but vary considerably as regards intensity, so that one or other may for a certain number of years become inactive. Their real existence is proved by the fact that whenever they reappear after a period of inactivity, the phase of the renewed periodic action fits in exactly with the continuation of the old period.

A periodicity of about 4·78 years runs through the whole of the observations. Its amplitude being about one-sixth of that of the eleven-year period is too great to be accounted for by accident. It appears separately in the series of Wolf's numbers, ranging from 1749–1826 and from 1826–1900. It also appears in the series depending on the measurement of areas. The phases of the period as determined from these series are in good agreement, and even while I was inclined to question the permanency of the eleven-year period I never felt any doubt that during the whole length of 150 years this period has been acting. Its time, determined as accurately as possible from the combined records, was 4·81 years, but I believe that if greater weight were given to the more recent and more complete observations the number would be slightly reduced. As regards the main period, which has certainly given its character to the sun-spot statistics during the greater part of the last century, I find the time as determined from the observations since 1826 alone to be 11·125 years. This agrees well with Wolfer's estimate of 11·124, and Newcomb's investigation, which led to 11·13 as the most probable number.

If to the most accurate series of measurements of sunspot areas which begin in 1832 we apply a process the result of which is the elimination of the chief period, and draw a curve representing what is left, we find decided maxima during the years 1836, 1845, 1853, 1862, and 1870, the intervals being alternately 9 and 8 years, or 8·5 years on the average. The periodogram based on Wolf's numbers for the complete interval 1749–1900 shows a decided maximum of intensity for a periodicity of 8·25 years. Adopting this period provisionally, and disregarding all observations since 1826, we may use Wolf's series previous to that date for the determination of the phase of the period in question, and thus forecast the maxima for the subsequent interval. We thus obtain 1836·3, 1844·7, 1852·9, 1861·2, 1869·4, in almost exact agreement with the above. The slight disagreement of phase would be corrected by assuming the time to have been 8·32 years.

A periodicity of about 13·5 years shows as a maximum of intensity in the periodogram for the complete interval. In connection with it the following facts seem remarkable. There are in Wolf's records three cases of successive maxima having an interval of between 13 and 14 years. They are:—1626·0–1639·5, 1816·4–1829·9, 1870·6–1883·9. Also the interval between 1639·5 and 1816·4 is thirteen times 13·61, and the interval between 1829·9 and 1870·6 is three times 13·57. Thus the maxima all fit in with a period of about 13·6 years, which with varying intensity seems to have run through the whole record of observations.

Not wishing to lay too great a stress on what may prove to be merely a numerical coincidence, I return to the three periods which have been determined with some accuracy. It was only after the periodic times had been independently determined that the following remarkable relationship between the numbers was discovered. Taking frequencies into consideration, we are led to form the reciprocals of the periodic times, and thus find

$$1/11{\cdot}125 = 0{\cdot}08989$$
$$1/8{\cdot}32 = 0{\cdot}12019.$$

Adding up we find

$$1/4{\cdot}76 = 0{\cdot}21008.$$

Hence the sum of the frequencies of two of the periods agrees within the possible errors with the frequency of the third period. But it is also found that the two first numbers are very nearly in the ratio of three to four, so that we may also express the three periodic times as subperiods of 33·375 years. Thus

$$\tfrac{1}{3} \times 33{\cdot}375 = 11{\cdot}125$$
$$\tfrac{1}{4} \times 33{\cdot}375 = 8{\cdot}344$$
$$\tfrac{1}{7} \times 33{\cdot}375 = 4{\cdot}768.$$

How far this connection is accurate or approximate it is impossible to say at present, but the fact that the three periods which have been traced with a considerable degree of certainty should also bear a remarkably simple relationship to each other is worthy of note.

If we accept a period twice as long as that given above, we might account for other periodicities of which at present the times are only approximately determined; thus $\frac{1}{5} \times 66{\cdot}75$ would lead us to 13·34, in fair agreement with the period of 13·57 years which has been mentioned above. But the difference is greater than it should be, and at the present I do not wish to put forward the longer.

ARTHUR SCHUSTER.

NATURAL HISTORY AND ARCHÆOLOGY OF THE WATERLILIES.[1]

MR. CONARD has embodied the result of several years' work on the waterlilies in the sumptuous volume before us. The monograph opens with an historical account of the plants as they were known to the ancients, and then deals with the group from a modern botanical point of view.

An interesting part of the memoir deals with the morphology and development of the plants, and the reader will find much that is worth reading therein. It must be confessed, however, that, taken as a whole, this portion occupies a somewhat large number of pages in proportion to the amount of valuable information it contains. The structure of the root is given at some length, but one would have liked to see a comparative treatment given that embraced not only the roots of different species, but also those of an individual plant at various stages of the life-history. Possibly such an investigation might throw light on the nature or origin of the "Liorrhizic" character of the roots in the waterlilies. Mr. Conard gives a good account of the formation of the intercellular spaces and the diaphragms so characteristic of the order, and he mentions an interesting occurrence of stomata on the under surface of the aërial leaves that rise above the level of the water in *Nymphaea odorata* var. *minor*.

The occurrence of stipules is a point of some note, and it may be remarked that their absence from the early leaves of the seedlings detracts from their phylogenetic significance in the group.

A short sketch of the development of the flower is included in the monograph, and we think it might have been considerably extended with no small advantage. The flowers, as is well known, occupy a remarkable position in waterlilies, where they apparently replace a leaf. The author was led to adopt a suggestion made by Caspary as to the morphology of the flower which explains the anomaly and at the same time appears to fit the facts of development. The anterior sepal, which appears first, and often well below the others, is regarded as morphologically representing the bract, whilst the two lateral sepals are

1 "The Waterlilies. A Monograph of the Genus Nymphæa." By Henry S. Conard. Pp. xiii+279. (Published by the Carnegie Institution of Washington, 1905.)

in like manner formed at the expense of the two prophylls. A similar explanation, it may be remarked, has been advanced, also on good grounds, to explain the otherwise anomalous character of the flower and inflorescence in *Adoxa moschatellina*.

The chief part of the work is devoted to the taxonomy of the group and to the description and delineation of the different species. Distribution and hybridisation are briefly considered, and a short chapter on the culture of the waterlilies is added; the work closes with an excellent bibliography.

The illustrations are numerous, and many of them are finely executed in colour, whilst the paper and printing leave nothing to be desired even by the most fastidious bibliophile. The book certainly deserves a place on the shelves of those who are interested in a group more beautiful than most, and perhaps inferior to none, of the plants that are cultivated for the beauty alike of their form and of their colour.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The general board has nominated the following as electors to professorships:—Prof. W. A. Tilden to the professorship of chemistry, Sir W. D. Niven to the Plumian professorship of astronomy, Sir A. Geikie to the professorship of geology, Prof. J. J. Thomson to the Jacksonian professorship of natural philosophy, Sir W. H. Broadbent to the Downing professorship of medicine, Dr. L. Fletcher to the professorship of mineralogy, Prof. Larmor to the professorship of experimental physics, Sir W. H. White to the professorship of mechanism and applied mechanics, Prof. Schafer to the professorship of physiology, and Dr. J. F. Payne to the professorship of pathology.

Mr. A. R. Brown, of Trinity College, has been elected to the Anthony Wilkin studentship in ethnology and archæology. This is the first election which has been made to this recently founded studentship.

THE Goldsmiths' Company has voted a further sum of 1558*l*., in addition to its previous endowment of the Goldsmiths' College at New Cross, to defray the expenses of putting the buildings in complete working order.

UNDER the auspices of the Society for the Technical Education of Women, founded a few years ago by Mrs. P. N. Arian, a technical high school for women was opened in St. Petersburg on January 28. The new high school has two faculties, one for engineering and building subjects, and the other for electrochemistry, and provides a four-year course in each, which courses it is intended shall be of the same educational standard as those in the same subjects in the present technical high schools.

WE have received a copy of a well illustrated "Souvenir" of the opening last year of the new engineering and metallurgical laboratories of the University of Sheffield. In view of the illustrated article published in NATURE for July 20, 1905, describing the new buildings at Sheffield, it is unnecessary to do more than direct attention to the excellence and great extent of the provision made in this new university for teaching the higher branches of applied science. It is possible from the numerous well executed pictures in the souvenir to form a good idea of the laboratories and their equipment without a visit to Sheffield.

Science announces further munificent gifts to higher education in the United States. Mr. John D. Rockefeller has given 290,000*l*. to the University of Chicago. Of this sum, 200,000*l*. is for the permanent endowment, 70,000*l*. to cover the current expenditures or deficit of the various departments of the University to July 1, 1907, and the remaining 20,000*l*. is to provide a fund, the interest of which is to go to the widow of the late President Harper during her lifetime. By the will of the late Mr. Marshall Field, Chicago receives 1,600,000*l*. for the endowment and maintenance of the Field Columbian Museum. The bequest is on condition that within six years from the death of Mr. Field there shall be provided a satisfactory site for the permanent home of the museum. By the will of the late Mr. W. C. Putnam, the Davenport (Iowa) Academy of Sciences becomes prospectively one of the most richly endowed institutions of its kind in the world. Mr. Putnam left an estate of 140,000*l*. with provisions for limited incomes to relatives, the remainder of the revenues to be paid to the academy, and the entire estate to go to that institution at the death of the surviving brothers and sisters.

UNDER the leadership of Dr. Chiari, a member of the Austrian Government, a petition was recently laid before the Austrian Minister of Education in which the teaching of chemistry in the technical high schools was given the most prominent place. The petition affirmed that the present conditions of the chemical laboratories in the high schools had repeatedly been the subject of severe criticism in technical circles; that neither the space provided, the existing equipment nor the teaching staff was at all adequate to the requirements of modern chemistry. The backwardness of Austrian chemical laboratories could not but most seriously affect the chemical industries; indeed, in no other branch of commerce was a direct and intimate connection with the high schools so absolutely essential. The schools had been neglected, and consequently it was found that instruction in general technical chemistry and the intensive study of those branches of technical chemistry which were particularly suited to Austria had not received that amount of attention which they needed. A scheme involving the erection of a new chemical institute in Vienna was laid before the Government last year. The petitioners desired a speedy settlement of the existing misunderstandings on this subject, as they considered the building of such a chemical institute the first condition to an increased interest in Austrian chemical industries.

A copy of the address delivered by Sir Alexander R. Binnie at the recent distribution of prizes to students of the Merchant Venturers' Technical College, Bristol, has been received. The address dealt in broad outline with education and with what it in a certain sense implies, the acquisition of knowledge. Answering the question, How do we obtain knowledge? Sir Alexander Binnie said it can only be obtained through those senses with which human beings are endowed. First, knowledge includes sensations directly conveyed, that is, personal knowledge. Then there is knowledge of the world conveyed in books, that is, the teaching of authority; and there is a third, an all important division of knowledge, derived partly through observation, and partly through the mysterious property called mind. Observation and reasoning lead, especially in the line of science, to certainties greater, often more sure and more truthful, than those received through the senses. Later in the address Sir Alexander Binnie urged that in all these matters of education it is necessary to be careful; arrogance and self-conceit are quite out of place. There are limitations to all, but in the study of nature, and the great truths that nature reveals, the human mind is enlarged and its conceptions are elevated. In all the knowledge acquired during the years that human beings are permitted to indulge in that wonderful spectacle which nature presents, a preparation is being undergone, and it is to be hoped an advancement from a lower to a higher grade of mind.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 7, 1905.—"The Determination of the Osmotic Pressures of Solutions by the Measurement of their Vapour Pressures." By the Earl of **Berkeley** and E. G. J. **Hartley**. Communicated by W. C. D. Whetham, F.R.S.

The authors find that Ostwald and Walker's "bubbling" method of determining the lowering of the vapour pressure of solutions is unsatisfactory. They therefore use a form of apparatus such that dry air is allowed to pass over the solution, while the latter is continuously stirred, and then over the solvent. By placing two vessels containing

the solution in series, the constancy of weight of the second vessel indicates that the air has been saturated up to the vapour pressure of the solution. The total quantity of vapour given off by the solution and solvent is absorbed by sulphuric acid, and the gain in weight of the latter should equal the loss sustained by the two former. With solutions in water, it is pointed out that, on account of the condensation of solvent in the tube leading to the sulphuric acid, this never quite obtains. The loss of weight of the solution in conjunction with that of the solvent give, however, the data for calculating the osmotic pressure. It is shown that Arrhenius's formula, when applied to concentrated solutions, does not connect the true osmotic pressure with the lowering of vapour pressure; and a more correct relation is deduced from a consideration of the hydrostatic pressures about a column of solution which is closed at the lower end by a semi-permeable membrane, and is partially immersed in the solvent. It is found that the osmotic pressures of cane-sugar solutions when calculated by way of vapour pressures and when observed directly agree to within 5 per cent. of one another over a range of 20 to 110 atmospheres.

January 25.—"Artificial Double Refraction, due to Æolotropic Distribution, with Application to Colloidal Solutions and Magnetic Fields." By Dr. T. H. **Havelock.** Communicated by Prof. J. Larmor, Sec.R.S.

The sections of the paper are summarised as follows:—

(1) The formal investigation of artificial double refraction in colloidal solutions as due to a deformation of the medium consisting of a change in the packing of the colloidal particles.

(2) The possibility that such deformation may be produced by mechanical stress as arising from the possession of a certain amount of rigidity by such solutions.

(3) The analogy between the effects so produced and the double refraction due to a magnetic field.

Linnean Society, January 18.—Prof. W. A. Herdman, F.R.S., president, in the chair.—Coloured transparencies from flowers in natural colours: T. E. **Waltham.**—The life-history of *Margaritifera Panasesae*: A. W. **Allen.** The paper was interesting as the result of close observation in the field, though practically all had been observed by other observers in various parts of the world, and of various nationalities.—Some endophytic algæ: A. D. **Cotton.** The observations referred chiefly to *Endoderma viride*, Lagerh., which occurs abundantly in the tissues of *Nitophyllum Hilliae*, Grev., a deep-water alga, only obtainable by dredging. The author also gave the result of his study of *Streblonema intestinum*, Holmes and Batters, based upon Reinsch's preparations in the Kew herbarium.—The organ of Jacobson in Sphenodon: Dr. A. **Broom.**

February 1.—Prof. W. A. Herdman, F.R.S., president, in the chair.—The Percy Sladen Trust Expedition in H.M.S. *Sealark* to the Indian Ocean: J. Stanley **Gardiner.** Accounts of the work and results of the expedition were given by Mr. Gardiner in Nature of April 13, August 10, October 5, November 9, December 21, 1905, and January 25 of the present year.

Anthropological Institute, January 23.—Prof. W. Gowland, president, in the chair.—Annual meeting.—Annual address: copper and its alloys in antiquity: **President.** Smelting had its origin in the camp fire, from which the first primitive furnace, a hole in the ground, used even now in parts of Japan, naturally evolved. The lumps of copper discovered in "founders' hoards" had clearly been smelted in this way. The hole was first filled with charcoal, over which was placed the ore, then another layer of charcoal, then more ore, and so on; the draught was obtained by the wind or by primitive bellows. The smelted copper was not run off, but, at the moment of solidification, was pulled out of the fire and broken into pieces on a large stone. This system is still practised in Korea, while the implements used by primitive man have their counterpart at the present day in the tools used by the native smelters in some parts of Africa. Turning to the question of bronze, Prof. Gowland stated that in his opinion this was made directly from a copper ore containing tin, long before the two metals were mixed. In Hungary a copper ore containing antimony takes the place of a copper-tin ore, and the implements found there frequently contain antimony in considerable amounts. He defined bronze as an alloy of copper and tin containing not less than 2 per cent. of tin; lead, arsenic, zinc, &c., being present in very small quantities. The president was of opinion that there was no evidence of a true Copper age in Europe, excluding only Cyprus, which was, of course, exceptional. Copper implements were only used by primitive man as adjuncts to stone implements, which were more efficient as weapons, and when found are only copies of stone implements, or when made in the Bronze age take the form of the implements of that period. In its simple form a copper celt could only be made in an open mould, and therefore only flat celts could be made of copper. The opinion often maintained, that the intention of the makers of bronze weapons was to make an implement in the proportion of 9 : 1, was shown by analysis to be incorrect, as also was the theory that the art of tempering bronze was lost, as it could now be hardened by hammering as well as, if not better than, it was done in the Bronze age. The lecturer also clearly proved that metallic tin was not necessary to the manufacture of bronze, and bronze celts made by him by melting metallic copper with tin ore, and from metal obtained by smelting a mixed ore of copper and tin in a primitive furnace in the metallurgical workshop of the Royal School of Mines, were exhibited. He also showed conclusively that the opinion held by many of the existence of a universal Copper age in Europe, intermediate between the Bronze and Stone periods of culture, was not warranted by the facts of the case.

Geological Society, January 24.—Dr. J. E. Marr, F.R.S., president, in the chair.—The igneous and associated sedimentary rocks of Llangynog (Caermarthenshire): T. C. **Cantrill** and H. H. **Thomas.** The sedimentary rocks associated with the igneous masses comprise Lower Old Red Sandstone, Didymograptus-bifidus beds, and Tetragraptus beds of the Ordovician. They occur in two anticlines, overfolded, and complicated by thrusts. The igneous rocks occur in three well defined areas, which belong to the same petrographical province. Both interbedded and intrusive rocks are represented; the latter include diabases and a large porphyry mass. The extrusive rocks occur in the following order:—(1) augite-andesites; (2) rhyolites; and (3) augite-andesites. The extrusive rocks are interbedded with fluxion-breccias and with tuffs; they are associated with the lower members of the Tetragraptus beds, and are consequently of Lower Arenig age; while the intrusive rocks have been injected into the extrusive rocks, and have also affected the Tetragraptus beds.—The Buttermere and Ennerdale granophyre: R. H. **Rastall.** From the facts put forward it is concluded that the intrusion is an example of an acid-magma, which has crystallised under the set of conditions that gives rise to a perfect development of granophyric structure. The masses appear to be of the "cedar-tree" laccolite type intrusive about the junction of the Skiddaw Slates and the Borrowdale rocks. Besides the normal acidic rock, there are some marginal patches of more basic character, showing obvious genetic relationship. These basic forerunners afford evidence of differentiation of the magma before intrusion an example of Prof. Brögger's deep-magmatic differentiation. Considered as a whole, the character of the magma shows closer affinity to the tonalite group than to the true granites. The more basic types include dolerites, quartz-dolerites, and a rock type intermediate between quartz-dolerites and granophyres. There is also a development of peculiar rock types as the result of the re-mixing of previously differentiated partial magmas of an acid and a basic character respectively.

Challenger Society, January 31.—Dr. R. N. Wolfenden in the chair.—Four deep-water Caridæ from the west coast of Ireland: S. W. **Kemp.** *Acanthephyra purpurea*, a species showing so great variation that it is now possible to rank six other "species" as its synonyms; *A. debilis*, a very rare species with about 100 luminous organs; *Ægeon brendani*, and *Leontocaris lar*, spp. nn.—Report on the Chætognatha of the *Siboga* expedition in the Dutch East Indies: Dr. **Fowler.** Of sixteen species, only one appeared to be new. Among those taken only in deep

hauls were *Sagitta macrocephala* and *S. zetesios*, known only from deep water in the Atlantic, and *Krohnia hamata*. The species captured at the surface supported the alleged uniformity of the Indo-Pacific epiplankton. A systematic revision of all species hitherto described left twenty-four as valid. A revision of all captures of Chætognatha hitherto recorded appeared to show one (*hexaptera*) as cosmopolitan and pantothermal, others as eurythermal, and having a wide but not a universal range, others as confined to a limited area and stenothermal. As regards depth, four have been only recorded from the mesoplankton; two at the surface in polar waters seek the mesoplankton in warm seas; others are confined to the epiplankton. According to temperature, species appear to fall into five classes:—cold water species with a maximum of about 12° C., temperate species, warm water species with a minimum of about 16° C., species with a wide range of temperature, and a single pantothermal species. The writer also presented a note on Antarctic and sub-Antarctic Chætognatha taken on the *Discovery* and *Challenger* expeditions; these established *Krohnia hamata* as truly bipolar, from 81° 30′ N. to 77° 49′ S., and completed the cosmopolitan record of *hexaptera*; they also enabled the N. limit of *hamata* at the surface, and the S. limit of *serratodentata*, to be determined approximately.

Chemical Society, February 1.—Prof. R. Meldola, F.R.S., president, in the chair.—Hydroxylamine-$\alpha\beta$-disulphonates: T. **Haga**. These salts, obtained by hydrolysis of Fremy's *m*-sulphazilates, are decomposed by sodium amalgam, and are proved by the nature of this change to be hydroxylamine-$\alpha\beta$-disulphonates. This is believed to be the first indisputable case of the occurrence of fundamental structural isomerism among inorganic compounds.—Studies in the camphane series, part xxi., benzenediazo-ψ-semicarbazinocamphor and its derivatives: M. O. **Forster**. Compounds of this class have been obtained from diazotised aniline, *p*-toluidine, &c.; they are characterised by the readiness with which dilute alkalis resolve them into camphoryl-ψ-carbamide and the corresponding phenylazoimide.—The relations between absorption spectra and chemical constitution, part i., the chemical reactivity of the carbonyl group: A. W. **Stewart** and E. C. C. **Baly**. It is pointed out that in certain cases the phenomena of tautomerism furnish an explanation of the exceptional reactivity of the carbonyl group. From spectroscopic evidence it appears that in the α-diketones a vibration is going on, which, to a certain extent, resembles that which was found in the case of ethylacetoacetate and its derivatives. The nature of this vibration cannot be easily expressed in the ordinary structural formulæ without the possibility of misconception, but it may be indicated somewhat as follows:—The vibration is brought about by some change in the relations between the carbon and oxygen atoms, and in some respects resembles the transition from the ketonic to the enolic form and back again. Using this analogy, it may be postulated that the two extreme phases of the vibration can be represented by the formulæ

$$\begin{array}{ccc} \text{—C.O} & \qquad & \text{—C:O} \\ \| \;\; | & & \\ \text{—C.O} & & \text{—C O} \\ \text{I.} & & \text{II.} \end{array}$$

It is proposed to call the general phenomenon "isorropesis," and to call "isorropic" those radicals the activity of which is thus produced.—The relation between absorption spectra and chemical constitution, part ii., the quinones and α-diketones: E. C. C. **Baly** and A. W. **Stewart**. In this paper it is shown that isorropesis in α-diketones results in the absorption of light in the visible blue region, so that the substances are intensely yellow. This is evidenced by camphorquinone and diacetyl. These observations strongly support Armstrong's theory that the colour of certain benzene derivatives is due to the quinonoid linking, for they show that the colour is caused, not directly by this linking, but by the isorropesis between the unsaturated atoms where this linking exists.—The relation between absorption spectra and chemical constitution, part iii., the nitranilines and the nitrophenols: E. C. C. **Baly**, W. H. **Edwards**, and A. W. **Stewart**. In this paper are described the absorption spectra of compounds having the quinonoid linking and containing a nitrogen atom in place of one or both of the quinone oxygen atoms. In the discussion, Prof. Armstrong said that Mr. Baly had put aside entirely the view which had long been held that ketonic interactions were conditioned by the combination of various substances with the carbonyl group, and had adopted an entirely *intra*-molecular view of change, whether chemical or physical. He still adhered to the opinion that three absorbing centres were required to produce visible colour, *i.e.* that iodoform, not methylene iodide, might be taken as typical of coloured substances. The colour of compounds such as diacetyl might be accounted for on the assumption that polymeric molecules were present, formed by the association, through the residual affinity of the oxygen atoms, of the ketonic groups, *e.g.*

$$\begin{array}{l} CH_3.\underset{\cdot\cdot}{C}\text{—}\underset{\cdot\cdot}{C}.CH_3 \\ \quad\;\; O \;\;\; O \\ \quad\;\; \dot{O} \;\;\; \dot{O} \\ CH_3.\dot{C} \;\;\; \dot{C}.CH_3. \end{array}$$

This explanation might perhaps also apply to metanitrophenol and metanitraniline. He remarked subsequently that the blue colour of water might be accounted for from this point of view, but not by Mr. Baly's hypothesis.—The action of light on benzaldehydephenylhydrazone: F. D. **Chattaway**.—The union of chlorine and hydrogen: C. H. **Burgess** and D. L. **Chapman**.—Note on the molecular weight of epinephrine: G. **Barger** and A. J. **Ewins**.—The critical temperature and value of ML/Θ of some carbon compounds: J. C. **Brown**. The value of ML/Θ rises very slightly with the increase of CH_2 in the aliphatic alcohols, acids, and esters, but is very constant for the aromatic hydrocarbons.—Slow oxidations in the presence of moisture: N. **Smith**.—Fischer's salt and its decomposition by heat: P. C. **Rây**.—Action of quinones on *o*-diamines, *o*-nitroaniline, *m*-nitroaniline, and 2-nitro-*p*-toluidine. A preliminary note. Some oxidation products of the hydroxybenzoic acids, ii.: A. G. **Perkin**. When gallic acid dissolved in 76 per cent. sulphuric acid is oxidised by means of potassium persulphate, a colouring matter very similar to ellagic acid is produced. This substance, to which the name flavellagic acid is assigned, is probably hexahydroxydiphenylmethylolid.—Contributions to the chemistry of oxygen compounds, part i., the compounds of tertiary phosphine oxides with acids and salts: R. H. **Pickard** and J. **Kenyon**.—The rapid electro-analysis of metals, preliminary note: H. J. S. **Sand**.

Mathematical Society, February 8.—Sir W. D. Niven, vice-president, in the chair.—The Eisenstein-Sylvester extension of Fermat's theorem: Dr. H. F. **Baker**. Sylvester gave in 1861 an expression for the residue, to modulus p, where p is an odd prime, of the integer $(\gamma^{p-1}-1)/p$. The result admits of simple proof and of extension to the case where the modulus is not prime, and the expression obtained for the residue is shown to be one of a definite number of possible representations.—A chapter of the present state in the historical development of the elliptic functions: Prof. H. **Hancock**. The paper deals chiefly with the contributions of Cayley and Eisenstein to that method of developing the theory of elliptic functions which is usually associated with the name of Weierstrass.—The reduction of the ternary quintic and septimic to their canonical forms: Prof. A. C. **Dixon** and Dr. T. **Stuart**. The method employed in the reduction is Sylvester's extended dialytic method of elimination.—The scattering of sound by spheroids and discs: J. W. **Nicholson**. The diffraction of plane sound waves by a very small spheroid has been discussed by Lord Rayleigh. The paper is occupied with the development of formulæ suitable for expressing the scattered waves in the case where the axis of the spheroid is parallel to the direction of the incident disturbance, and the dimensions of the spheroid are sufficiently small compared with the wave-length for an approximation proceeding by powers of the ratio of the equatorial radius to the wave-length to be valid.—A preliminary communication on partitions of numbers in space of two dimensions was made by Major P. A. **MacMahon**.

DUBLIN.

Royal Dublin Society, January 16.—Dr. W. E. Adeney in the chair.—Secondary radiation from compounds: Prof. J. A. **McClelland** and F. E. **Hackett.** The secondary radiation of β particles emitted by substances when they are acted upon by the β rays of radium has been previously measured by one of the authors for a large number of elementary substances. In the present paper a number of chemical compounds have been tested experimentally, and the secondary radiations from the compounds have also been calculated on the assumption that the secondary radiation is an additive atomic property. The close agreement between the calculated and the experimental value shows that the assumption is fully justified. This result is then used to determine the secondary radiation from a number of elements not available in sufficient quantity in the pure state to enable them to be studied directly. The relations previously established between the secondary radiation and the atomic weight are found to hold for all the additional elements thus investigated.—Electromagnetic mass: Prof. A. W. **Conway.** The electromagnetic inertia of an invariable system of electric charges is considered. A quadric is obtained such that if the force has the direction of the radius vector, the "mass" in that direction is as the inverse square of the length, and the direction of the acceleration is the perpendicular on the tangent plane. The mean mass of any such system is $4/3\,C^{-2}$, the work necessary to assemble it from a state of infinite diffusion.—Note on the sublimation of sulphur at ordinary temperatures: R. J. **Moss.** Twenty-five years ago some fragments of ordinary stick sulphur were enclosed in a glass tube, which was then exhausted by a Sprengel pump and sealed. After the lapse of twenty years indications of the formation of a crystalline sublimate became apparent; during the past five years the crystals have increased in number and in size to a marked extent; some of them are now 0·2 mm. in length, and the sublimate is deposited on one side of the tube throughout its whole length. The crystals are apparently rhombic, and are much more complex than those deposited from sulphur solutions.

EDINBURGH.

Royal Society, February 5.—Prof. Crum Brown, vice-president, in the chair.—The relation between normal "take-up" (or contraction) and degree of twist in twisted threads: T. **Oliver.** The paper was chiefly devoted to the properties of two-ply twisted yarns. The effect of twisting together two already twisted single threads was studied theoretically, and special attention was directed to the lengthening in the early stages of the second twisting due to the opening out of the single threads as the second twist was applied in the opposite direction to that of the first twists. Formulæ were deduced connecting the change of length with the amount of twist, and these were then compared with the results of experiment. The comparison was satisfactory, the discrepancies being such as might naturally be expected when due consideration was given to the necessarily imperfect nature of the assumptions on which the theoretical calculations were made. For example, the beginning of the contraction in the second twisting, when experimentally tested, occurred at a later stage than was indicated by the theoretical formula, a discrepancy which could be explained by the extremely probable supposition that the yarn had acquired a "set" in one direction during the first twisting.—Some experimental results in connection with the hydrodynamical theory of seiches: P. **White** and W. **Watson.** These experiments were undertaken at the suggestion of Prof. Chrystal, and the results obtained gave striking confirmation of several of his theoretical conclusions. The seiches were generated in a rectangular trough 5 feet long and 4·5 inches wide. Various bottom contours were obtained by means of blocks of wood cut to the desired form, such as parabola, concave or convex, semi-parabola, symmetrical rectilinear slope, and the quartic form which Prof. Chrystal had found to lead to a simple solution. The seiches were started by the to-and-fro motion of a strip of wire gauze placed at the position of a node of the required seiche, and kept in proper periodic motion by means of an attached heavy pendulum the length of which could be adjusted. By this method seiches of nodalites as high as the fourth, fifth, and even seventh, had in certain cases been obtained. The periods of these were easily determined, but the positions of the nodes and ventral segments could not be determined with the same accuracy. Within the errors of observation, the agreement with theory was generally very close. It was found that with the convex parabolic bottom the seiches were not so persistent as in the case of the concave bottom, but that the trinodal was more persistent than the uninodal. With the quartic contour of bottom the seiches were remarkably persistent up to that of the fourth nodality.

PARIS.

Academy of Sciences, February 5.—M. H. Poincaré in the chair.—On the existence of insoluble potassium compounds in the trunk and bark of the oak: M. **Berthelot.** On the rotatory powers of hexahydrobenzylidene and œnanthylidenecamphors and their corresponding saturated derivatives, compared with the rotatory powers of benzylidene and benzylcamphors: A. **Haller** and F. **March.** These compounds were chosen for comparison since they contain the same number of carbon atoms, the substituting groups, benzylidene, hexahydrobenzylidene, and œnanthylidene, containing gradually increasing numbers of hydrogen atoms. Details are given of the methods of preparation of the various compounds, and of their physical properties. The conclusion is drawn that in benzylidenecamphor and its analogues, as in the benzylcamphors, it is the unsaturated character of the benzene ring which exerts its action on the elevation of the rotatory power of the asymmetric molecule to which it is attached.—Contribution to the chemical study of sea-water: Th. **Schlœsing.** A discussion of the results of chemical analyses of samples of sea-water taken at various points in the Mediterranean. The water of the Mediterranean differs from that of the Atlantic only by its degree of salinity, the mineral constituents of the two oceans being nearly identical.—Quasi-waves of shock, and the distribution of temperature in these quasi-waves: P. **Duhem.**—The provisional elements of the comet 1906*a*: E. **Maubant.** The calculations are based on observations made on January 29, 30, and 31.—Observations made on the sun at the Observatory of Lyons with the 16 cm. Brunner equatorial during the third quarter of 1905: J. **Guillaume.** The results of observations on forty-four days are summarised in three tables giving details of the spots, their distribution in latitude, and the distribution of the faculæ in latitude.—A problem in the calculus of variations: Erik **Holmgren.**—The general solution of the problem of equilibrium in the theory of elasticity, in the case where the displacements of the points of the surface are given: A. **Korn.**—Some results of the triangulation of the Pelvoux-Écrins massif: Paul **Helbronner.** The present paper deals with the rectification of the heights of some of the important peaks.—The condensation of the acetylenic nitriles with alcohols. A general method of synthesis of β-substituted β-oxyalkyl acrylic nitriles: Ch. **Moureu** and I. **Lazennec.** The nitrile $R—C\equiv C—CN$ is treated with alcoholic potash; the product is poured on to ice, extracted with ether, and submitted to distillation in a vacuum. The compound $R—C(OC_2H_5)=CH—CN$ is thus obtained. In the case of the aromatic compounds, this substance is easily hydrolysed by heating with dilute sulphuric acid, furnishing the ketone $R—CO—CH_2—CN$; with fatty compounds the hydrolysis is more difficult, and generally results in further changes.—Attempts at reduction in the diphenylamine series: H. **Duval.** A study of the effects of stannous chloride and zinc dust in alkaline solutions on azo-diaminodiphenylmethane.—Cyclohexylacetone: P. **Freundler.** The only method, out of several tried, which has given the desired ketone is the condensation of the iodide of hexahydro-benzyl-magnesium with acetaldehyde. The secondary alcohol thus obtained is oxidised to the ketone with chromic acid mixture. The yields are not good.—The absorption of alkaline carbonates by the mineral constituents of the soil: J. **Dumont.**—Observations on the preceding note: L. **Maquenne.**—The passage through the spinal ganglions of bundles arising from the motor roots and leading to the dorsal nerves in the Batrachians: P. **Wintrebert.**—The action of hordenine sulphate on soluble ferments and on micro-organisms: L. **Camus.** The sulphate of hordenine

retards the action of pepsin, trypsin, and rennet, but is without action on invertine, maltase, and lipasidin. It exerts an antiseptic action on bacilli.—The proportions of chloroform contained in arterial blood during anæsthesia and the effects produced: J. **Tissot.** There appears to be no direct proportion between the amounts of chloroform present in arterial blood and the anæsthetic effects produced.—Contribution to the study of the pathological anatomy of epithelial cancers of the prostate: MM. **Motz** and **Majewski.**—Trepanning and ventricular puncture in brain disease: O. **Laurent.**—The existence of limestone breccias in the mountains to the south-east of Mt. Blanc: M. **Kilian** and P. **Lory.**—Results of magnetic observations made at the Observatory of Athens during the years 1900–1903: D. **Éginitis.**—Note on an earthquake shock at Ebro: P. **Cirera.** The instruments at the Observatory of Ebro registered a shock between 3.47 p.m. and 6 p.m. on January 31. The magnetograph showed corresponding disturbances.

New South Wales.

Linnean Society, November 29, 1905.—Mr. T. Steel, president, in the chair.—Further notes on hybridisation in the genus Eucalyptus: J. H. **Maiden.** This paper briefly recapitulates recent work on the subject, directs attention to the fact that the credit of the discovery of natural hybridisation in this genus belongs to George Caley, whose observations were made in New South Wales before 1810, and indicates the guides which point to a natural hybrid.—Miscellaneous notes (chiefly taxonomic) on Eucalyptus, part ii.: J. H. **Maiden.** Reasons are given for the contention that the blue or flooded gum of coastal New South Wales (*E. saligna*, Sm.) cannot in reality be separated from the Bangalay (*E. botryoides*, Sm.), and the name var. *botryoides* is proposed for the latter.—On an undescribed species of Cryptocarya from eastern Australia: R. T. **Baker.**—Studies on Australian Mollusca, part ix.: C. **Hedley.** The marine molluscan fauna of New South Wales is enlarged by the addition of new species of Eulimella, Diala, Actæon, Mitromorpha, Rissoa, Bornia, and Cyamiomactra.—Descriptions of three new Australian species of the genus Austrogomphus (Neuroptera: Odonata): R. J. **Tillyard.** (1) A pleomorphic slime-bacterium; (2) the probable identity of the opsonins with the normal agglutinins: R. Greig **Smith.**

DIARY OF SOCIETIES.

THURSDAY, February 15.

Royal Society, at 4.30.—The Influence of Increased Barometric Pressure on Man. No. 1: Dr. L. Hill, F.R.S., and M. Greenwood.—On the Existence of Cell-communications between Blastomeres: C. Shearer.—Innervation of Antagonistic Muscles. Ninth Note: Successive Spinal Induction: Prof. C. S. Sherrington, F.R.S.—The Chemical Constitution of Protoplasm as shown by the Rate of Tissue Disintegration: Dr. H. M. Vernon.—The Development of the Head-Muscles of the Common Fowl (*Gallus domesticus*), together with some Remarks on the Head-Muscles of Reptiles: Prof. F. H. Edgeworth.—Observations on the Labyrinth of Certain Animals: Dr. A. A. Gray.

Chemical Society, at 8.30.—Cuprous Formate: A. Angel.—The Solubility of Triphenylmethane in Organic Liquids with which it forms Crystalline Compounds: H. Hartley and N. G. Thomas.—The Spontaneous Crystallisation of Supersaturated Solutions: H. Hartley.—The Preparation and Properties of some New Tropeines: H. A. D. Jowett and A. C. O. Hann.—Studies in Asymmetric Synthesis, Part IV., The Application of Grignard's Reaction for Asymmetric Syntheses: A. McKenzie.

Linnean Society, at 8.—The Structure of *Isis hippuris*: J. J. Simpson.—Note on the Geographical Distribution of the Genus Shortia, Torr. and Gray: B. Daydon Jackson.—*Exhibition*: Developmental Changes in Zooglœa (with Lantern Slides): Dr. H. Charlton Bastian, F.R.S.

Society of Arts, at 4.30.—The Navigable Waterways of India: R. B. Buckley, C.S.I.

Institution of Mining and Metallurgy, at 8.—Pyritic Smelting: R. C. Alabaster and F. H. Wintle.—The Acme Combined Concentrating Table: L. H. L. Huddart.—Stadia in Careful Work: A. H. Webb.—The Detailed Mapping of Stoping Areas: H. R. Sleeman.—Sinking, Development and Underground Equipment of Deep Level Shafts on the Rand: A. E. Pettit.—The Hydraulic Filling of a Coal Seam at Lens, Pas de Calais, France: L. E. Hill and M. Butt.

FRIDAY, February 16.

Royal Institution, at 9.—The Passage of Electricity through Liquids: W. C. D. Whetham, F.R.S.

Institution of Mechanical Engineers, at 8.—Large Locomotive Boilers: G. J. Churchward.

Geological Society, at 3.—Annual General Meeting.

SATURDAY, February 17.

Association of Teachers in Technical Institutes (Regent Street Polytechnic), at 7.30.—The Teaching of Mathematics to Engineering Students: G. E. St. L. Carson.—The Teaching of Mathematics to Building Trade Students: H. Bustridge.

MONDAY, February 19.

Society of Arts, at 8.—Modern Warships: Sir William White, K.C.B., F.R.S.

Victoria Institute, at 4.30.—The Bible Pedigree of the Nations of the World: M. L. Rouse.

TUESDAY, February 20.

Royal Institution, at 5.—Food and Nutrition: Prof. W. Stirling.

Institution of Civil Engineers, at 8.—A Plea for Better Country Roads: G. R. Jebb.—Country Roads for Modern Traffic: J. E. Blackwall.

Royal Statistical Society, at 5.—Wages in the Engineering and Shipbuilding Trades in the Nineteenth Century: A. L. Bowley and G. H. Wood.

Zoological Society, at 8.30.

WEDNESDAY, February 21.

Society of Arts, at 8.—Fisheries of the North Sea: Walter Garstang.

Geological Society, at 8.—The Constitution of the Interior of the Earth, as revealed by Earthquakes: R. D. Oldham.—The Tarannon Series of Tarannon: Miss Ethel M. R. Wood.

Royal Microscopical Society, at 8.—On an Improved Method of taking Stereophotomicrographs and of Mounting the Prints: H. Taverner.—Exhibition of Slides of Oribatidæ, presented by N. D. F. Pearce.

Royal Meteorological Society, at 7.30.—Report on the Phenological Observations for 1905: E. Mawley.—Discussion of the General Features of the Pressure and Wind Conditions over the Trades-Monsoon Area: W. L. Dallas.—The Dispersal or Prevention of Fogs: Dr. W. B. Newton.

Sociological Society (School of Economics and Political Science, University of London, Clare Market, W.C.), at 8.—A Practicable Eugenic Suggestion: W. McDougall.

THURSDAY, February 22.

Royal Society, at 4.30.—*Probable Papers*: On the Coefficient of Viscous Traction and its Relation to that of Viscosity: Prof. F. T. Trouton, F.R.S.—An Account of the Pendulum Observations made at Kew and Greenwich Observatories in 1903: Major G. P. Lenox-Conyngham.—And other Papers.

Institution of Electrical Engineers, at 8.—Crane Motors and Controllers: C. W. Hill.

FRIDAY, February 23.

Royal Institution, at 9.—The Internal Architecture of Metals: Prof. John O. Arnold.

Physical Society, at 5.

Institution of Civil Engineers, at 8.—The Graphical Determination of the Deflection of Beams: C. H. Sumner.

CONTENTS.

regarded by many people as something quite *chic* and up to date!

In conclusion, Mr. Cunynghame may claim to have presented us with a very clear and well expounded introduction to the important subject of which his book treats.

G. H. B.

TWO EGG-BOOKS.

(1) *Ootheca Wolleyana: an Illustrated Catalogue of the Collection of Birds' Eggs formed by the late John Wolley.* Edited by Alfred Newton. Part iii., Columbæ to Alcæ. (London: R. H. Porter, 1905.) Price 2*l.* 2*s.*

(2) *Eggs of the Native Birds of Britain and List of British Birds, Past and Present.* By W. J. Gordon. Pp. 64; 398 illustrations. (London: Simpkin, Marshall and Co., Ltd., 1905.) Price 3*s.* 6*d.*

In the first of these two books Prof. Newton makes good progress with the catalogue of the unrivalled collection of eggs to which it is devoted, dealing in this instance with the pigeons, game-birds, rails, cranes, bustards, waders, gulls, and auks. Needless to say, it is written in the same style as its two predecessors, consisting almost entirely of Mr. Wolley's original notes, with such comments as the editor considered it advisable to intercalate here and there. To review the fasciculus is impossible within the limits of our space, and we can only refer to a few points of special interest. One of these relates to the eggs of the knot, of which a presumed specimen, laid in confinement, was given to the author by Lord Lilford; the correctness of this identification has been recently confirmed by the discovery of "wild" specimens. Equally interesting is the record of the first known egg of the stint, obtained by Middendorf in Siberia in 1843. The culminating interest of this fasciculus is, however, concentrated on the superb series of eggs of the great auk possessed by Mr. Wolley, which included no less than seven actual specimens, together with several casts. The first of the originals the author bought in 1846 for twenty-eight shillings; it may, perhaps, be now worth ten times as many pounds! Coloured figures (two of each) of the seven auks' eggs and of one of the casts form the illustrations to this fasciculus; and in the execution of these plates Mr. H. Grönvold has surpassed himself, having succeeded not only in showing the colouring and markings to perfection, but also in imitating to a nicety the very grain and texture of the shell. The eight specimens show very clearly the range of variation to which the colour and markings of the eggs of the species were subject.

Mr. Gordon's little book, which is, of course, a work of quite a different class from the last, is a well-intended attempt to place before the public, at a very low price, a satisfactory means of identifying the eggs of those birds which nest in the British Isles, or did so until within a comparatively recent period. That the author has taken great pains in grouping and photographing these eggs is perfectly evident, and if the colouring of the figures is in some instances not quite so true to nature as might be desired, this can scarcely be considered his fault, while, if the low price at which the book is published be taken into consideration, it would be almost unfair to lay the blame on the lithographer. We cannot have perfection combined with cheapness in matters of this sort, and, considering its price, the book is a very creditable production.

In including extinct species of British birds in the list at the end of his work, Mr. Gordon has, we think, been ill-advised, as the majority of these are very imperfectly known, and they are not likely to interest the class of readers to whom this volume will appeal. Still, the inclusion is evidence of broad views on the part of the author. Both Prof. Newton and Mr. Gordon, we are glad to find, remain staunch conservatives in the matter of nomenclature, both as regards the use of generic terms in a wider and more comprehensive sense than is now, unfortunately, the fashion, and above all in eschewing the detestable "*Pica pica*" system. In both these respects, we venture to think, Mr. Gordon's work (the other does not, of course, appeal to the same class) will be far more acceptable to the general public than would have been the case had the author been induced to yield to the prevalent (and we trust fleeting) fashion

R. L.

OUR BOOK SHELF.

Engineering Chemistry: a Manual of Quantitative Chemical Analysis for the Use of Students, Chemists, and Engineers. By Thomas B. Stillman. Third edition. Pp. xxii+597. (Easton, Pa.: The Chemical Publishing Co.) Price 4.50 dollars.

At the present day chemical knowledge is so important a factor in the successful conduct of nearly all technical work that such books as Stillman's "Engineering Chemistry" appeal to a very large audience, and so well has the professor of analytical chemistry in the Stevens Institute done his work that the third edition will be as warmly welcomed as its predecessors. In it much of the work has been revised, the most modern standard methods introduced, and a considerable amount of new matter added, those portions on lubricating oils and the technology of the blast furnace being especially noticeable.

In so excellent a work criticism always seems ungracious, but there are a few points the author would do well to correct in the next edition. For instance, on p. 169 the author gives as a typical analysis of London coal gas

Hydrogen	27·70
Methane	50·00
Carbon monoxide	6·80
Ethylene	13·00
Nitrogen	0·40
Oxygen	0·00
Carbon dioxide	0·10
Aqueous vapour	2·00
	100·00

and calculates that it would have a heating value of 870·15 B.T.U.'s gross.

Such an analysis is so absurdly wrong that it can only have been inserted by error, the main constituents more nearly approximating to hydrogen 50 per cent., methane 36 per cent., and ethylene 4 per cent.

Moreover, the author on p. 183 says that London coal gas has an illuminating value of 16 to 17 candles, and a calorific value of about 668 B.T.U.'s, which is much more nearly true for the gas supplied by the Gas Light and Coke Co. The error is of importance, as an engineer working at the problem of the gas-engine and consulting records of efficiency made with London gas might be seriously misled.

In dealing with water gas, no mention is made of the more modern processes such as the "Dellwik," now so largely used for the production of blue gas for welding, as well as for diluting coal gas.

It is admitted in the preface that the article on practical photometry has not been brought up to date, and this is a pity, as more than seven pages are devoted to the Bunsen photometer and the manipulation of candles, now practically extinct in all but name as a standard of light, whilst a couple of pages on pentane standards would have been of real value.

In spite of a few blemishes, the whole work is so good that no engineering chemist can afford to be without it.

Die Photographie im Hochgebirg. By Emil Terschak. Second edition. Pp. xxiii+62. (Berlin: Gustav Schmidt, 1905.) Price 2.50 marks.

EVERYONE who is of a roving disposition, and takes his camera to Switzerland or the Tyrol, or any other region where mountain climbing is pursued, should, if he wishes to gain by the experience of others, read this book. It is written by a photographer to photographers, and is not only very interesting to read, but contains a great amount of very useful photographic information of a particular kind.

The successful photography of mountain scenery, of ice, snow, and clouds at high altitudes requires not only forethought, but much experience. As it is necessary to carry all the apparatus that is required, the equipment must be well attended to, and since also one does not necessarily wish to climb high altitudes to take again a particular view that has not turned out photographically successful, one must be sure of securing a good negative at every exposure.

The first edition of this book appeared in 1900, but the author has since gained much more useful knowledge, which he has embodied in the present edition. The book is clearly printed in Roman characters on good paper, and the illustrations are numerous and well reproduced.

The Royal Medical and Chirurgical Society of London. Centenary 1805–1905. Written at the request of the President and Council by Dr. Norman Moore and Stephen Paget. Pp. 337. (The Aberdeen University Press, Ltd., 1905.)

THOUGH not the oldest of the medical societies of London, the Royal Medical and Chirurgical Society holds a position second to none, and the present volume of chronicles will not only be welcomed by its Fellows as giving a history of their society, but forms a useful record of the art and science of medicine during the nineteenth century, with comments by the compilers. A noteworthy feature of the volume is the list which is given for each year of the principal papers read before the society, both published and unpublished, extracts being given from the more important ones. Thus, for the year 1833, we find Hilton's unpublished account of *Trichina spiralis* in human muscle, which ante-dated Paget's discovery of this parasite. Short bibliographies of all the presidents and a full index complete this interesting volume, which contains several illustrations of the various premises occupied by the society and a photogravure frontispiece of William Saunders, the first president.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Tidal Researches.

IN NATURE for January 11 (p. 248) appear some criticisms upon my paper entitled "Cotidal Lines for the World."

The critic says:—"The construction of these charts is, unfortunately, but vaguely indicated." In reply to this it may be said that the charts embody all data known to me at the time of their construction, and to such data references as copious as space seemed to permit are given. What is meant by cotidal lines is given in § 17. Notions relating to the local modifications or peculiarities of cotidal lines have been given in considerable detail by means of lemmas and examples. In the construction of these lines, large detailed charts showing soundings wherever known were employed, and these depths were carefully considered in each step of the process. The ranges of tide written along the shore-lines simply represent data, and in no way depend upon any theory or hypothesis. The same is essentially true of the cotidal lines where observations or data are sufficient. Wherever harmonic constants are available, the length of the series analysed is of secondary importance in the construction of cotidal lines, the results from two months being about as satisfactory as those from twenty years.

If we are not permitted to extend cotidal lines outward from the shore, we might about as well draw them upon the land as upon the water, for in either case they would only serve to point out the shore values. The reviewer thinks well of Berghaus's chart, and so do I. However, it is difficult to believe that a philosophical critic could long rest content with cotidal lines extending but a short distance off shore, and forming no connected or consistent system. Of course, the attempt, on my part, at covering all seas does not imply that all charts are equally good. In some instances the data were very meagre, and attention was directed to this fact more than once in the paper.

It seems strange that any serious misunderstanding could exist in reference to the method employed in inferring the times when the water particles are at elongation in particular directions. Does anybody doubt the conclusions reached in § 56, part iv. A? If these conclusions are wrong, let us hear the correct ones. If §§ 60–65, part iv. A, are not clear as they stand, it seems as if § 24, part iv. B (to say nothing of a reply to former criticism, NATURE, April 23, 1903), ought to remove all obscurity.

Perhaps the following remarks may be of some service in this connection:—

Unless the free period of a body of water, or of some portion of this body, approximately agrees with the period of the tidal forces, the tide in the body proper must be small, and generally smaller than the theoretical equilibrium tide for the body in question. But in many parts of the oceans the tide is several times greater than that which could be raised by the forces, even if we could suppose sufficient depths and sufficiently complete boundaries for enabling equilibrium tides to occur. Hence regions the dimensions of which approach critical values must exist in the oceans and account for the principal tides. If the aërial vibrations accompanying a musical tone act upon a series of resonators suited to various pitches, the one or more constructed for the given tone will respond to it, while all others will be practically silent; that is, the dominant impressed motions belong to resonators having critical dimensions, and not to the resonators in general.

That stationary oscillations of unexpectedly large amplitude exist in the oceans there is abundant evidence. In fact, a glance at the charts under criticism will show regions of large ranges over each of which the time of tide varies but little. As a nodal line is approached the range diminishes, and the time of tide changes rapidly in a comparatively short distance. Moreover, the dimensions of the oceans are such that areas having nearly critical

lengths can be readily discovered; these respond well to the forces, and their tides must be the ruling semi-diurnal tides of the oceans. The charts prove the existence of large stationary oscillations. To doubt this fact would be scarcely more reasonable than to doubt the existence of the tide itself. The large ranges of tide imply critical lengths, and critical lengths imply that the phase is controlled by the resistance to the movement.

In a second approximation it may be possible to take into account the actual departures from critical lengths, to make some numerical estimates of the resistance, and to fix more accurately the modes of oscillation having regard to the deflecting force of the earth's rotation. In my paper the latter effect has been considered only in reference to arms or bodies of water tidally dependent upon larger bodies.

As soon as my critics develop their tidal theories sufficiently far for making definite suggestions, I shall be pleased and bound to give such developments careful consideration. In the meantime, I believe that nothing is gained by criticism which does not constantly revert to such facts as have been brought out through observations upon the tides. These constitute the final test of all theories. R. A. Harris.

Washington, D.C., January 26.

It is Mr. Harris's theory with which we were, and continue to be, at variance. We were unable to gather the part played by this theory in the construction of his series of cotidal charts, and hence our statement that this construction was but "vaguely indicated"; but we are glad to be assured that the theory has only been employed in regions where observational data were entirely wanting, and has not been allowed to vitiate, as we feared, results obtained direct from observation.

In reference to the phase theorem which we selected for special comment, Mr. Harris now states that "the large ranges of tide imply critical lengths, and critical lengths imply that the phase is controlled by resistance." The latter part of this theorem we are not prepared to admit unless it be further contended that the critical conditions implied are mathematically *exact*, especially in consideration of the comparatively small frictional influences which can be brought to bear on the motions of the sea. Any departure from the ideal critical state, and we contend that such departures must inevitably occur in a complex system like that of the ocean, will render the determination of phase dependent on such departures as well as on frictional influences, and we differ from Mr. Harris in regarding the former rather than the latter as the more powerful controlling influence in regard to phase. Whence can the large resistances to motion, implied in Mr. Harris's theory, arise? S. S. H.

Atomic Disintegration.

According to the investigations on radium, especially by Prof. Rutherford, there can be no longer any doubt that the formation of helium from radium is due to spontaneous disintegration of the radium atom, and it is the same with the other radio-active elements. Most competent investigators have not hesitated to apply the same point of view also to all the other elements.

The enormous amount of energy set free in the formation of helium—about 10^9 great calories for a gram-atom of helium—must render hopeless any attempts to reverse this process. Considering the conformity of the other gases of the helium type—neon, argon, krypton, and xenon—it seems probable that they owe their existence to a similar disintegration of atoms. It is not surprising, therefore, that all attempts have failed to obtain a chemical compound of those gases, and I do not think such attempts likely to succeed in future. That, as yet, those gases, excepting helium itself, have not been recognised as products of atomic disintegration may be due to their difficult test.

Now it seems to me there is nothing contrary to the view that *disintegration of atoms is an irreversible process, strictly analogous to dissipation of heat.*

Considered in this way, there exists a parallelism not only as regards the first law of thermodynamics—conservation of energy—with the principle of conservation of matter, but also regarding the second law—dissipation of energy, on the one hand, and atomic disintegration on the other. And as it has been stated by Clausius that the world's entropy tends towards a maximum, we may say that likewise the quantity of free helium and the similar "Edelgase" tends towards a maximum.

This parallelism in material and energetical law appears to me well worthy of notice. W. Meigen.

Freiburg i/Br.

Phosphorescence of Pyro-soda Developer.

Some time ago (January, 1904) you were good enough to publish a note on the "Phosphorescence of Photographic Plates," and the following additional particulars of this phenomenon may be of interest. The developer used is the ordinary pyro-metol-soda solution.

If a bromide plate is exposed in the camera, developed, washed for a few moments only, and then placed in aluminium sulphate solution in the dark, the picture becomes luminous and shows forth as a *negative*, the high lights being dark, whilst the shadows are bright, the darkest ones phosphorescing most strongly. If, however, the plate (after having been exposed and developed) is washed thoroughly for half an hour by means of a jet of water under pressure, no phosphorescence is observed on treating it with Al_23SO_4 solution, from which it appears that a trace of the developing solution is necessary to cause phosphorescence in the plate.

If a few spots of unused developing solution are placed in the bottom of a porcelain dish and Al_23SO_4 solution is added (in the dark), the mixture will phosphoresce. But if the developer has been used for developing exposed plates, then its power of phosphorescence is weakened, and if the same portion of solution is used repeatedly for developing, and tested periodically for phosphorescence between the developments, it will be found that its phosphorescing power is diminished after each development, and that it finally vanishes altogether. This explains the production of the phosphorescing negative. The most strongly lighted part of the film is that which will destroy the phosphorescing power of the developer it has absorbed, and the unlighted portion or shadow is that in which the absorbed developer will be least changed, and therefore most strongly phosphorescent.

The addition of various substances to the aluminium salt modifies its phosphorescing power, and some prevent it altogether, even when added in very small quantities. Among those substances which strongly counteract the phosphorescence may be mentioned the salts of thorium, uranium, copper, lead, bismuth, iron, tin, cobalt, nickel, chromium, zinc, cadmium, mercury, platinum, and silver in the order named, while the salts of potassium, sodium, ammonium, lithium, calcium, barium, strontium, magnesium, and manganese seem to have little influence one way or the other.

The only substance found which has the effect of much increasing the brilliancy of the phosphorescence is gold. A solution of $AuCl_3$ alone, in fact, gives a more brilliant phosphorescence than Al_23SO_4. The gold is reduced to the black metallic form, and while this reduction is proceeding light is emitted. Other reducing agents, however, do not appear to emit any light during the process of reduction of $AuCl_3$. The influence of the other metals on the phosphorescing power of the gold solution seems to be practically the same as for aluminium.

Other aluminium salts, such as the nitrate, phosphate (dissolved in HCl), chloride, &c., phosphoresce with pyrometol developer, but none so brilliantly as the sulphate.

Emission of Light by Kanal-strahlen Normal to their Direction.

In a former publication (*Physik. Zeitschrift*, vi., 892, 1905) I have proved that the stream of positive ions which form the Kanal-strahlen show the Doppler effect. In these rays we have, therefore, a positive charge, and at the same time velocity, and also, as a result of the vibrations of the negative electrons, emission of light. Therefore it is

exerting a pressure on the ions against the translation resulting from radiation; besides this force an electromagnetic force—of second order of the ratio of velocity of translation to velocity of light—may arise from the moved charges of the ions and act on the vibrating electrons. The experimental research of the light of Kanal-strahlen emitted normally to their direction has given the following results. The observations have been made on hydrogen; the velocity of the Kanal-strahlen was $0{\cdot}9.10^8$ and $1{\cdot}2.10^8$ cm. sec.$^{-1}$. The spectrograms were taken with a prism-spectrograph and with a concave grating of 1 metre radius.

The total radiation of the line spectrum ($H\alpha$, $H\beta$, . . .) is partially polarised, and the electrical vibrations parallel to the direction of translation have a greater intensity than the vibrations at right-angles to the direction of translation. The difference of intensities is very small.

The lines of hydrogen (when observed normal to the Kanal-strahlen) are displaced towards the red, when compared with the lines emitted by the slow ions in the negative glow. The displacement seems to be proportional to the wave-length, and also proportional to the square of velocity. The displacement of the centre of $H\beta$ is approximately 0·8 Ångström unit for a velocity of $1{\cdot}2.10^8$ cm. sec.$^{-1}$.

Besides this displacement there is observed a broadening of the lines; it seems also to be proportional to the square of velocity, and to increase somewhat with decrease of wave-length. The observations as to the splitting up into components of the broadened line, and also as to the polarisation of its edges, are not concordant enough in the different spectrograms, and are therefore not ready for publication. J. STARK.

Göttingen, January 6.

Inversion-point of the Joule-Kelvin Effect.

IN discussing the Joule-Kelvin effect for a fluid like hydrogen, which shows an inversion point above which heating takes place on free expansion, it is usually assumed that this point is unique. Thus, for example, Olszewski has fixed it experimentally at $-80°{\cdot}5$ C. An examination of the consequences of any of the usually assumed equations of state (such as Van der Waals's or Dieterici's) easily reveals the fact that it must in reality be a function of the pressures to which the gas is subjected. But this is not all. If these consequences are examined for the inversion point corresponding to an infinitesimal change in pressure, it is seen that all the equations of state (which at the same time indicate a critical point) demand that there shall be *two* inversion points (if any) for any given pressure, and that, moreover, for sufficiently high pressures no inversion point will exist. Different equations of state, while unanimous in the above respects, indicate very different temperatures at which inversion should occur. I desire to point out, therefore, that a complete determination of the inversion points corresponding to various pressures affords an exceedingly sensitive means of discriminating between characteristic equations and of indicating the direction in which these require modification.

This matter is discussed in detail in a paper shortly to be published. ALFRED W. PORTER.

University College, W.C., February 19.

A Definition of Temperature.

A BODY containing heat is in a condition from which it tends to release itself (by radiating or conducting away heat), and this tendency only ceases when the body has passed into a heatless condition. The temperature of a body is the *measure* of its tendency at any instant to recover this heatless state (*cf.* Maxwell, "Theory of Heat," 10th ed., p. 32). This suggests a mechanical analogy; a body containing heat is analogous to an elastic medium in a state of strain, from which it tends to release itself in virtue of its restitutional forces; the magnitude of the restitutional force when a body is in a given strained condition measures its tendency to release itself from that strain, and so is analogous to the temperature of a body when in a given thermal condition. The quantity of work stored up in producing this strained condition, and which can be given out again when the body returns to its unstrained condition, is analogous to the quantity of heat the body contains when at a given temperature; it is quite easy to show that we can completely represent the thermal condition of a body by means of a model consisting merely of an elastic rod subjected to a tension. *A temperature, therefore, is analogous to a tension or pressure.* We are now in a position to give a real physical meaning to the "temperature" of a body, and so enable it to be measured in *absolute* units like a mass or a length. Let us take a molecular body devoid of all heat motion and plunge it into a medium the temperature of which is T. Then the medium will exert an intermittent pressure or force on the molecules, thus setting them into motion and generating heat motion in the body. It can easily be shown that this force cannot be infinite, or a cold body placed in a hot medium would *instantly* acquire the temperature of the medium, whereas it always takes a definite time to do so.

The *maximum force* which the medium exerts on a molecule at rest when placed therein is the numerical value of its temperature. Hence we arrive at the following definition of temperature:—

A molecule at rest when placed in a medium possessing temperature is subjected to an intermittent pressure; the greatest value of this pressure is the correct measure of the temperature of the medium in the neighbourhood of the molecule. Another method of stating the same thing is to say that the greatest force required to hold a molecule at rest when placed in a medium is the measure of the temperature of the medium. Still another statement is to say that the temperature of a medium is the magnitude of the force tending to drive heat motion into an absolutely cold body placed therein. A temperature, therefore, should be measured as a pressure in *dynes* per sq. cm. All the ordinary laws of thermodynamics, the flowing of heat from bodies of higher to bodies of lower temperature, Waterston's hypothesis, &c., follow quite simply as a consequence of this definition, as the reader can doubtless work out for himself. GEOFFREY MARTIN.

Kiel, February 10.

Chinese Names of Colours.

IN reply to the letter of Mr. Alfred H. Crook contained in your issue of January 11, I would say that it is possible that the explanation of the Chinese colour-name is to be found in the violet coloured halo which is very commonly noticed by Alpine climbers surrounding moving objects. Dr. Ellis attributes it, I believe, to fatigue of the eye (see discussion in NATURE, May, 1897).

REGINALD A. FESSENDEN.

IN your issue of January 11, Mr. Alfred H. Crook, of Hong Kong, asks why the Chinese should call a bright purple (almost a mauve) "snow green," and he adds that the term "green" is sometimes applied to the colour of the sky, which I take to mean blue. The following is a possible explanation:—

One of the commonest places in nature to find purplish hues is in shadows, and shadows on the snow, when the sky is clear, are decidedly purple. If purple is to be classified among the colours, it will go with the blues, hence "snow green" as meaning "snow blue" would not be such a misnomer as might at first sight appear.

Pittsburg, Pa., February 7. ALFRED SANG.

Sounding Stones.

MR. ALFRED TINGLE (January 4, p. 222) and Mr. Carus-Wilson (January 11, p. 246) may be interested to know that at the caves of Ellora, near Aurangabad, one of the pillars in the rock-cut temples has the same property of sounding under a blow.

The pillar is a massive one close to, or part of, the doorway leading to an inner shrine, and if struck with the clenched fist emits a deep note.

So far as I recollect, this property was confined to a portion of the pillar. W. G. BARNETT.

Poona, January 29.

THE NILE QUEST.[1]

THE story of the search for the sources of the Nile is the longest and most interesting in the annals of geographical exploration. It dates from the earliest days of geography; it has ever presented new problems; and the quarrel over the boundary between the Congo Free State and British East Africa, in the Upper Nile basin, is the latest example of political muddles due to geographical ignorance. The sources of the Nile roused speculation in the earliest days of Egyptian geography, owing to the mysterious rising of the Nile at the driest and hottest time of the year. The view that the river rises owing to the melting of equatorial snows was for long accepted; but it is now known to be the effect of the rainy season on the Abyssinian Mountains, as the contribution from the equatorial snowfields is insignificant, and even the great reservoir, the Victoria Nyanza, gives only a minor addition to the Egyptian floods. The story of the Nile is of especial interest to British students of geography, as the larger share to the solution of its problems has been contributed by British explorers, and practically the whole of the Nile basin, with the exception of Abyssinia, is now under British administration.

The story of the exploration of the Nile is here well and interestingly told. Sir Harry Johnston is known for his literary skill, and for the artistic sense which leads him to denounce (p. 161) "the unspeakable barbarism of the British Administration" in cutting down the fine trees that once grew beside the Ripon Falls; and his distinguished success in the administration of Uganda has given him an especial personal interest in the sources of the Nile, and full access to the latest information. His volume is worthy of a place among the excellent geographical handbooks in Dr. Scott Keltie's "Stories of Exploration." Sir Harry Johnston begins his narrative in the times when, as he tells us (p. 18), 2500 years ago, Phœnicians or Sabæans worked the goldfields of Rhodesia, and with the story of Diogenes, told to Marinus of Tyre in the first century, and preserved to us by the record of Ptolemy in the second century. He continues the history to recent surveys made under the British and Anglo-Egyptian administrations. The story is so long and so full that in 318 pages the author is able to give only brief sketches of the various expeditions. But he gives an exceptionally complete list of them, and his short, critical sketches are a most useful introduction to the original literature. The most valuable part of the book is its account of the minor expeditions, and especially of those carried on from Khartoum from 1840 to 1860. The author writes with wide sympathy for the explorers of all races and all nations, and he gives foreign workers their full share of praise, including Mademoiselle Tinné, "the gracious demi-goddess" of the Egyptian Soudan, and Georg Schweinfurth, "one of the greatest of African explorers." He defends d'Abbadie against the unjust attacks of Beke, and reminds us that Paez and Lobo were predecessors of Bruce. He describes the journey of Marchand (p. 245) as "one of the most splendid feats in African exploration." The author perhaps somewhat underrates the early contributions of the Portuguese; but he reprints a copy of Dapper's map of 1686; so he enables the reader to judge for himself as to the extent of the facts then known about tropical Africa, and as to the nature of the mistakes made by European cartographers in their interpretation of the verbal reports of the untrained Portuguese travellers. D'Anville's map, which is much praised by the author, is less accurate in regard to the

FIG. 1.—A Hima of Mpororo, near Karagwe. From "The Nile Quest."

Upper Nile and the Victoria Nyanza than Dapper's, though issued nearly a century later, and nearly a century and a half later than some of the authorities whom Dapper copied. The Portuguese mistake of giving several outlets from Tanganyika, which Sir Harry Johnston says shows that the Portuguese were "ignorant of the simplest principles of hydrography," was a similar mistake to that made by his own hero, Speke, in giving too many outlets from the Victoria Nyanza. The author quotes with praise Scott-Elliot's "very neat and truthful little map of the eastern and southern flanks of Ruwenzori, a map which until quite recently has been somewhat overlooked by those who have compiled charts of this

[1] "The Nile Quest, a Record of the Exploration of the Nile and its Basin." By Sir Harry Johnston, G.C.M.G., K.C.B., in "The Story of Exploration," edited by Dr. J. Scott Keltie. Pp. 365 (London: Alston Rivers, Ltd.)

region" (p. 269). The ethnographical and zoological references in the book show high expert knowledge, but it may be noticed, perhaps with surprise, that on pp. 297 and 298 he accepts the theory of the marine origin of the fauna of Lake Tanganyika.

The illustrations in the book are numerous and excellent, and it is illustrated by two fine maps by Bartholomew, showing the orographic features, and the characteristics of the surface and vegetation in north-eastern Africa.

FIG. 2.—In the Libyan Desert. From "The Nile Quest."

THE FORM OF THE ATOMS IN RELATION TO THEIR SPECTRA.

SINCE Balmer's important discovery in 1885 that it is possible to calculate the wave-lengths of the first nine lines of the hydrogen spectrum by means of a simple formula, the existence of series of lines, obeying simple mathematical laws, has been established in the case of the spectra of several other elements, notably by the researches of Rydberg and of Kayser and Runge. Among the various attempts that have been made to account for these series of lines, and, in general, for the different spectra, the most promising seems to be that of Prof. F. von Lindemann, of Munich, who in some recent papers[1] has more fully developed an idea that he was first led to enunciate in 1888, after the publication of Lord Kelvin's Baltimore lectures on molecular dynamics. Prof. von Lindemann's method consists, not in deriving an empirical relationship between the wave-lengths or frequencies of the spectral lines, but in investigating mathematically the possible waves which a hypothetical atom can send out into the luminiferous ether.

His assumptions are the simplest possible. His atom consists of a certain amount of elastic isotropic matter of definite shape. The mathematical theory of the different kinds of vibrations of which such a body is capable is well understood, but the actual working out for any special case is difficult because it depends on functions which have to be discovered for each shape, and are, generally speaking, new to mathematicians. The wave-lengths of each kind of vibration sent out into the ether appear always as roots of a transcendental equation involving those functions. Such an equation has an infinite number of roots, each when real corresponding to a definite line. One equation thus corresponds with a "series" of lines. The theory gives for one body a number of such equations, and therefore a number of such "series" of lines, which together form the whole spectrum. This agrees with observed facts.

Prof. von Lindemann investigates, in the first paper quoted, the case of a spherical atom, filled throughout with matter of a definite density and elasticity. In this case, which is comparatively a simple one, the

[1] "Zur Theorie der Spectrallinien," *Sitzungsber. Math. phys. Classen der Kgl. Bayer. Akad.*, 1901, xxxi., 441; 1903, xxxiii., 27; a lecture, printed in the *Suddeutsche Monatshefte* for September, 1905, of which a translation is published in the *Monist* for January of this year, contains a popular summary of the earlier work and an outline of results not yet published in detail.

calculation can be carried fairly far, but it is found that the spectral lines so deduced obey a law of distribution simpler than any that has yet been found by experiment to characterise any substance. Although atoms are usually assumed for physical calculations to be spherical, such a shape apparently is not really possessed by the atom of any substance; but by using the result established in this case, a simple relationship is shown to be necessary between the wave-lengths of the spectral lines of two *similar* elements and their atomic weights. If these two elements are conceived as being built up of the same material, having the same form, density, and elasticity, and only their size different, the wave-lengths of corresponding spectral lines of the two elements are shown to be proportional to the cube roots of their atomic weights; given the lines of one of the elements, those of the second element can be calculated from the equation

$$\frac{\lambda}{\lambda'} = \sqrt[3]{\frac{W}{W'}},$$

where λ and λ' are the corresponding wave-lengths, W and W′ the atomic weights of the two elements. The elements of the following groups are found to obey this rule with a greater or less degree of approximation:—

(1) Zinc, cadmium, and mercury.
(2) Magnesium, calcium, barium, and strontium.
(3) Silver, copper, and gold.

As an illustration, the following series of lines of magnesium and calcium may be given. The arrangement and wave-lengths are those adopted by Kayser and Runge.

Magnesium. Mg=24·4				Calcium. Ca=40·0.			
Subordinate Series.	n	Observed	Calculated	Observed	Difference	n	Subordinate Series
I	4	3838·46	4526·1	4527·1	−1·00	—	—

From the similarity of their spectra, the elements in each of the foregoing groups appear to be similarly constructed, and the probability of this is strengthened by the analogy of their chemical properties. On the other hand, chemical analogy does not necessarily imply similarity of form in the elements, as is shown in the case of the alkali metals (lithium, sodium, potassium, rubidium, cæsium); these elements, in spite of their close chemical similarity, do not exhibit the simple relationship connecting wave-length and atomic weight found in the groups already named. Either these elements may be considered as built up of different kinds of matter, or if of the same material as possessing different shapes.

Assuming that matter is uniform, the shape of the atom may be varied, and instead of the simple sphere the case of an elongated ellipsoid of rotation, formed by revolving an ellipse round its major axis, may be considered. The mathematical theory shows that the spectral lines of such a luminous ellipsoid depend on three numbers, and that therefore these lines will be capable of arrangement in groups according to three principles. These numbers are obtained as the roots of certain transcendental equations, and are to be calculated from the lengths of the axes of the ellipsoid, its density and elasticity, a calculation, however, which on account of its difficulty is hardly practicable. The first of the three numbers determines a group of corresponding lines, a so-called series; the different possible values of the number determine a certain sequence of such series. The second number determines in each series a subordinate group of lines, and the third number a single definite line in each subgroup. The manner in which this third number enters into the calculation shows, moreover, that the frequencies of the single lines in the subgroups will exhibit among themselves constant differences, differences, that is, depending solely on the nature of the given ellipsoid. A type of distribution of the spectral lines is thus afforded by the theory which corresponds with the well known law of distribution established by Rydberg and by Kayser and Runge in the case of the alkali metals. The atoms of these metals (Li, Na, K, Cs, Rb) may therefore be considered as elongated ellipsoids of rotation, the axial lengths being fully defined in the case of each element, and different in the different elements.

A flattened ellipsoid of rotation, the so-called spheroid, is by calculation found also to give rise to groups, series, and subgroups, but the law of constant differences is not so generally applicable. The roots of the transcendental equations are, in this case, partly imaginary, so that several groups consist of a single strong line, others of a limited number of lines. Such a grouping is actually found in the case of the metals gold, silver, and copper. Hydrogen is also of this type, its atom probably consisting of a thin, round plate, which is to be considered as the limiting case of a flattened ellipsoid.

In the more general type of ellipsoid, that with three unequal axes, the wave-lengths of the spectral lines also depend on three numbers, defined by certain equations, but in this case the lines cannot be arranged in series and groups, but range over the whole spectrum. Only when the form of the ellipsoid approximates to that of an ellipsoid of rotation will a few series arise. Such a distribution appears to obtain in the spectra of the alkaline earths (barium, strontium, calcium, and magnesium), that is, with elements lying intermediate in chemical behaviour between the alkalies and ordinary metals; the form here approaches that of the elongated ellipsoid of rotation. With zinc, cadmium, and mercury, the form approximates to the flattened type of the rotation ellipsoid.

Perhaps the most striking consequence of the theory is that which follows from an alteration in the shape of one of the simple ellipsoids of rotation. Such a solid can be imagined as being gradually strained in such a way that it passes into the more general ellipsoid with unequal axes. During such deformation the spectral lines will gradually and continuously change, and the mathematical theory predicates that out of each single line eight others can arise. It appears, indeed, that the Zeemann effect, or the resolution of a single line into two or more other lines under the influence of a magnetic field, is explicable on this hypothesis. It may be observed that the normal triplet which should result according to Zeemann's simple theory does not, as a matter of fact, occur by any means frequently, the arrangement of the resolved lines having been shown by recent work to be of a more complex character than was originally supposed. Such a complexity finds a simple explanation in Prof. von Lindemann's theory of strain.

Two other types of solids in addition to those already mentioned are susceptible of mathematical treatment, namely, the solids derived by the rotation of a circle round an axis not passing through its centre. When the axis does not cut the circle a ring with a circular section is produced, such as an ordinary finger ring, which is open at the middle. When the axis cuts the circle, a solid, which Lindemann calls a "*Wulst*" or roll, and resembles in form an orange or an apple—is generated. A particle having the first of these shapes, when rendered luminous, would, according to the mathematical theory, give rise to lines having wave-lengths dependent on four numbers, to each of which a series of values can be given. The kind of spectrum which results can best be explained by imagining the spectrum due to a luminous particle of the elongated ellipsoidal type to be displaced several times in succession, the relative position of the lines being slightly modified in each shift. Such a spectrum has already been found to characterise oxygen and helium; the oxygen spectrum, indeed, according to Runge and Paschen, appears as if derived from that of an alkali metal by a series of successive displacements. An atom of the second type, with a shape similar to that of an apple, when rendered luminous, would, according to the calculations, give rise to a spectrum such as would be produced by successive displacements of the lines due to a flattened ellipsoid. The spectra of sulphur and selenium seem, indeed, to be of this type, being derived from a spectrum like that of oxygen by substituting single strong lines for certain groups of lines. The atom of oxygen thus appears to have the form of an open ring, the atom of sulphur or selenium that of a "Wulst."

Certain interesting consequences concerning the chemical properties of the elements follow from a consideration of their shape, and have been developed by Prof. Lindemann. That the ring-shaped oxygen atom, for example, is a dyad with regard to hydrogen at once follows from the plate-like shape of the hydrogen atoms, two of these being necessary to close the two apertures of the ring. A distinction, moreover, such as is actually found to exist, is introduced at the outset between valency with regard to hydrogen and valency with regard to oxygen. Apart from speculations of this kind, Prof. von Lindemann's work has great significance at the present moment, in that it demonstrates the possibility to derive those physical constants which most clearly define and characterise the individual elements from the conception of a single kind of matter merely by introducing the idea of shape. It is, of course, possible that the atoms do not possess strictly, but only approximately, the simple shapes which can be treated mathematically. If this were so, slight changes would be introduced into the transcendental equations, and the deduced values, for example those in the table given, can be considered only as a first approximation; but the approximation is sufficiently close to justify the belief that the general type of the transcendental equations is correct. W. A. D.

THE TIME OF FRANCE.

A NOTE from the Paris correspondent of a daily journal stating that the proposal to adopt Greenwich time in France is again being brought forward, a desirable reform which would bring our nearest neighbour into harmony in this respect with almost the whole of Europe, may be considered a sufficient reason for giving some facts on the subject under discussion.

Without going back to the earliest proposals for establishing a time-system which should be common to the whole world, an early stage in the movement was the calling of a conference by the Government of the United States to be held at Washington in October, 1884. At this meeting, which was attended by representatives of twenty-five nations, but who, it must be remembered, had no power to bind their Governments to any plan of action, it was resolved that "the Conference proposes to the Governments here represented, the adoption of the meridian passing through the centre of the transit instrument at the Observatory of Greenwich as the initial meridian for longitude." This resolution was voted for by representatives of twenty-two countries, one representative took the opposite view, and two countries, of whom France was one, abstained from voting.

Following on this, a resolution was passed at the meeting adopting the principle of a universal day which should begin at mean midnight of the initial meridian, a scheme containing the germ of the present hourly zone system. But a more practical step had already been taken by the managers of the American railways, who, in November, 1883, had adopted the now well-known system in which the American continent is divided into five zones, the time used in each of which is respectively 4, 5, 6, 7, and 8 hours slow on Greenwich. It says much for the breadth of view of the American railway managers, who thus rose above all consideration of national feeling and selected a zero which was likely to suit the convenience of the greatest number, and set an example which must have done much to forward the scheme.

Since 1884 there has been no open international intercourse on the subject, but gradually the zone time system has made its way. In 1892 Belgium and Holland began to use Greenwich time; in 1893 mid-European time, one hour fast on Greenwich, was made the legal standard time in Germany and Italy; in the next year the same time was adopted in Switzerland and Denmark, and in 1895 in Norway. Mid-European time had already been in use in Sweden many years, and on the Austrian, Hungarian, Servian, and Macedonian railways since 1891, but, strangely enough, Vienna, the home of Dr. Schram, who was one of the leaders of the movement for the unification of time, has not adopted any legal standard time. The meridian of Pulkowa happens to be 2 hours 1 minute east of Greenwich, and since the time of this meridian is used for telegraph work and on the railways of Russia, it may be considered that this country uses east European time, two hours fast on Greenwich, which is also used for some purposes in Turkey. Since Greenwich time was made the legal time of Spain in 1900, it will be seen that almost the whole of Europe has fallen in line. France has not held aloof for want of consideration of its merits. In 1896 the proposition that the Greenwich meridian should be adopted in France was brought by M. Deville before the Chamber of Deputies, and being voted on was accepted by that body, but the matter went no further, the reason for which may be inferred from the proceedings at the meeting of the Astronomical Society of France held on December 2, 1896. At that meeting several of the leading scientific men of France were present, and among them M. Bouquet de la Grye, who, after expressing his astonishment that scientific men had not been consulted before such a proposition was made, proceeded to raise objections. It was true, said he, that the meridian of Greenwich had been chosen as initial because of the greatness of England's sea-power; but, he asked, how long would this continue? England's supremacy in this respect might pass away just as had that of other nations, and what then?

Also he urged that Greenwich was too far north as a situation for an observatory to fix the standard meridian, and again, that the position of Greenwich with respect to the observatories of the Continent was not then accurately known. Another speaker, whose opinions are worthy of respect, remarked that France was not alone among the countries in not joining the movement, for Spain used its own time, and also—it is to be feared that here he made a strong point—Ireland, even, still used Dublin time. It was affirmed that the motives which influenced the French authorities in this matter were purely of a scientific nature, but it may be noted that since that meeting the proposition has been brought forward in other words, namely, that the legal standard time of France shall be 9 minutes 21 seconds slow on the time of the meridian of Paris, which is not unlike the former proposal, except verbally, and it might be thought that the alteration was made so as not to hurt some susceptibilities. However, the change has not yet been made. Some of the objections above quoted have vanished, for England's naval power has as yet suffered no reverse, Spain has adopted Greenwich time, and the difference of longitude between Greenwich and Paris has been again determined, with a result which may be accepted as final. Ireland still continues to use Dublin time, it is true, but even this ought not to outweigh any advantages that might accrue from the change.

H. P. H.

THE COLOMBIAN EARTHQUAKE.

ON January 31, we learn from vague messages, an earthquake of unusual severity occurred in the north-west part of South America. The report stated that towns and villages had been destroyed, and islands had sunk. The disappearance of the latter was, however, so gradual that the inhabitants had been able to escape in boats. Later information told us about the interruption of cables, and reported that in consequence of huge sea waves a long line of coast between Buenaventura and Tumaco and the western coast of the Republic of Colombia had been devastated for many leagues. A great catastrophe had evidently occurred, but until sixteen days later the East knew but little as to what had actually taken place. The seismographs in Britain and in other countries have, however, told a story. Later we shall have another story from our Consuls and our newspapers.

In the Isle of Wight the record of some great earth adjustment commenced, as reckoned in our time, at 3h. 47m. p.m. Its maximum occurred some thirty-five minutes later. From these facts the distance at which the mass displacement had originated was known, and by a simple computation, based upon this distance, the time at the origin would be in Colombian time approximately 10h. 9m. a.m. Better that the disturbance occurred in the morning, when heavings of the ground could be felt and high waves suggesting refuge on higher ground could be seen, than it should have occurred when the inhabitants of towns and villages on a seaboard were at rest. Two hours later the effects of the initial impulses had reached their antipodes, and in the interval between these times every inhabitant of the world had been moved for at least three or four hours on a true ground swell. All the instruments in the world designed to record teleseismic motion had written records, the bubble in every spirit level had been fitfully oscillating to and fro, many magnetic needles had been caused to swing, balances had oscillated, pendulums had been accelerated or retarded—the whole world, not only on its surface, but in its depths had been shaken. The internal constitution of our planet had been disturbed, that which is hypogenic may have produced its effect upon that which was epigenic, there was a flicker in the life-history of the earth.

At this moment it is not for us to enter into the whys and wherefores of the Colombian disaster. It suddenly came upon the scene in the last day of January, but it is not yet ended. Shocks continued for the next five days, and although we are without information, they will doubtless continue for many days to come. Among other things beyond these immediate effects on life and property, we learn that volcanic stress was relieved at Cumbal. Further, we learn that on February 16 severe shocks were experienced in the Antilles. At 1.40 p.m. on that date walls were cracked in St. Vincent; similar reports come from Fort de France, and cables have been broken.

History repeats itself, and this is particularly illustrated in the seismic and volcanic history of the Central American and West Indian subterranean activities. A convulsion in the one is followed by a reaction in the other. The last illustration, which is only one of a long series, occurred in 1902, when terrific readjustments of strata in Guatemala were quickly followed by the holocaust of St. Pierre. The Colombian disaster of January 31, to which we particularly refer, is the last of a series with which seismologists are familiar. We do not know for certain, but its origin was probably suboceanic off the mouth of the Esmeralda River. We can at least say that on the line we have indicated there is a rapidly descending suboceanic gully, and that cables crossing this line have frequently been interrupted. To this we may add that here we have a district where submerged land slopes are unusually steep, and where those who lay deep-sea cables tell us that soundings have from time to time been greatly changed. Out of fifteen cable interruptions which have taken place in the district under consideration, nine of them occurred at the time when seismographs or instruments which would record teleseismic effects were set in motion in Europe. Interruptions to cables come in many ways, but from time to time we know that they have come about by sudden changes in the form of ocean floors, and off the mouth of the Esmeralda River we know that this has often happened.

NOTES.

THE appointment of officers for the seventy-sixth meeting of the British Association, which is to be held at York, has now been completed. The meeting will open on Wednesday, August 1—when the president, Dr. E. Ray Lankester, F.R.S., will deliver the presidential address—and be concluded on August 8. The following are the names of the presidents of the various sections:—A (mathematical and physical science), Principal E. H. Griffiths, F.R.S.; B (chemistry), Prof. Wyndham Dunstan, F.R.S.; C (geology), Mr. G. W. Lamplugh, F.R.S.; D (zoology), Mr. J. J. Lister, F.R.S.; E (geography), Sir G. Taubman-Goldie, K.C.M.G., F.R.S.; F (economic science and statistics), Sir George S. Gibb; G (engineering), Prof. J. A. Ewing, F.R.S.; H (anthropology), Mr. E. Sidney Hartland; I (physiology), Prof. Francis Gotch, F.R.S.; K (botany), Prof. F. W. Oliver, F.R.S.; L (educational science), Prof. M. E. Sadler. Subscriptions to the amount of more than 700*l*. have been promised to the fund started for the purpose of founding a medal to commemorate the visit of the association to South

Africa last year. The council of the association has resolved to add to the fund the balance of the special funds raised to meet the expenses of the South Africa meeting, so that the total sum to be disposed of is between 1500*l.* and 1600*l.* It is proposed that the medal, struck in bronze, together with the balance of the income on the fund after paying for the medal, shall be awarded "for achievement and promise in scientific research in South Africa," and that, so far as circumstances shall allow, the award shall be made annually.

PROFS. F. KOHLRAUSCH AND A. A. MICHELSON have been elected honorary Fellows of the Physical Society of London.

AN International Exposition, in which discoveries and inventions relating to medicine and hygiene will have a prominent place, is to be held at Antwerp in April and May of the present year, under the patronage of H.R.H. the Countess of Flanders. Communications should be addressed to the secretary's office, 26 Rue d'Arenberg, Antwerp.

THE anniversary meeting of the Geological Society was held on February 16. Sir Archibald Geikie, Sec.R.S., was elected president. The medals and funds awarded, as announced already (p. 274), were presented. The president delivered his anniversary address, which dealt with the influence of the geological structure of English lakeland upon its present features—a study in physiography.

IT is stated in the *Globe* of February 17 that the first wireless telegraph station at Machrihanish, Argyllshire, is now completed, and communication has been commenced with other stations in Great Britain. The tower, which is 400 feet high, has been built to the order of the National Electric Signalling Company, of Pittsburg, by the Brown Horsting Company, New York. The diameter of the column is about 5 feet, and consists of pipe-shaped tubes, inside of which are the ladders for ascending.

THE Milan Chemical Society has appointed a committee to undertake the compilation of a catalogue of the Italian chemical industries.

AT the invitation of the committee appointed to consider the foundation of a Chemische Reichsanstalt, a meeting was to be held yesterday in the Aula of the University of Berlin to hear an account of the steps which have already been taken by the committee, and the reasons put forward for such a chemical institution.

BY a decree of the German Chancellor, an advisory committee of specialists is to be appointed to the Imperial Biological Institute for Agriculture and Forestry. The following appointments, amongst others, have now been made to this committee, and hold good until the end of 1910:—Prof. J. Behrens, Baden; Prof. Buchner, Berlin; Prof. Delbrück, Berlin; Prof. Gärtner, Jena; Prof. Gerlach, Bromberg; Dr. Hiltner, Munich; Prof. Hollrung, Halle; Prof. Kellner, Leipzig; Prof. Kirchner, Würtemberg; Prof. Ludwig Klein, Karlsruhe; Prof. A. Koch, Göttingen; Prof. Kühn, Halle; Prof. Möller, Eberswalde; Prof. P. Wagner, Darmstadt; Prof. Wortmann, Geisenheim. The director of the Imperial Institute for Agriculture and Forestry has been elected president of the advisory committee.

ON Thursday next, March 1, Mr. Francis Darwin will deliver the first of three lectures at the Royal Institution on the "Physiology of Plants," and on March 3 Prof. J. J. Thomson will commence a course of six lectures on "The Corpuscular Theory of Matter." The Friday evening discourse on March 2 will be delivered by Dr. R. Caton, the subject being "Hippocrates and the Newly Discovered Health Temple at Cos," and on March 9 by Dr. R. Hutchison, on "Some Dietetic Problems."

THE thirty-third annual dinner of old students of the Royal School of Mines was held on February 16. After the loyal toasts, the chairman, Prof. S. H. Cox, was asked to present to Prof. J. W. Judd a service of plate with an address and an album containing the signatures of 400 of his pupils and friends in all parts of the world as a mark of their esteem on his retirement from the office of dean of the school. In the address warm appreciation is expressed of Prof. Judd's services to geological science during his tenure of the chair of geology from 1877 to 1905, and the interest he invariably showed in the work and welfare of his students. Prof. Judd, in reply, alluded to the recently published report of the Government committee, which, he said, has outlined measures that will form a basis for the re-organisation of the school as a great and flourishing institution worthy of the Empire. The wants of a technical institution are not, he continued, identical with those of a university, either of the ancient or modern type, and it will be a calamity if the distinctive features of their school are lost by its being drawn into the vortex of a university. In proposing the toast of "The School," the chairman also alluded to the report of the departmental committee, and said those associated with the school are desirous of preserving its identity and the degree of Associate of the Royal School of Mines. They one and all dread being absorbed by a huge scientific institution, of which they will become only a subsidiary branch.

AT a meeting held at the Mansion House last June it was decided to commemorate the achievements of the late Sir Henry Bessemer by a memorial, which should have for its object some educational work so far-reaching in its beneficent influence as are the results of Bessemer's invention. The memorial committee deferred the active prosecution of the scheme until the publication of the report of the departmental committee on the work of the Royal College of Science, and, now that this report has been issued, it is possible to proceed actively with the memorial scheme. The committee is confident that no memorial could be more appropriate than one which has for its object the scientific advancement of the metallurgical and mining industries, and that none would be more likely to have met with Bessemer's warm approval. It has been arranged that the objects of the memorial fund shall be:—(1) The establishment of open international memorial scholarships for post-graduate practical work tenable (except such as it is intended to allocate to the Royal School of Mines, the Sheffield and Birmingham Universities, the Armstrong College, Newcastle-upon-Tyne, or other approved British institutions) in any part of the British Empire, in the United States of America, and in Europe. It is intended that these scholarships shall be of such value, and shall be awarded under such conditions, that they will be regarded by students of any nation as a prize worth striving for, and as an incentive to the highest scientific attainment. (2) The equipment of mining and metallurgical memorial laboratories in the Royal School of Mines at South Kensington as the centre of the memorial. The land and the cost of the new buildings and maintenance for the school will be provided from Government and other sources. (3) The erection of a statue of Bessemer in the new Royal School of Mines at South Kensington. Subscriptions amounting to about 8000*l.* have already been

received towards the large sum which will be required. Communications should be addressed to the Hon. Secretary, Bessemer Memorial Fund, Salisbury House, E.C., and all cheques should be made payable to the "Bessemer Memorial Fund," and crossed "Bank of England."

We have received from the Philosophical Institute of Canterbury, New Zealand, copies of four papers by the late Captain Hutton published in the *Transactions of the New Zealand Institute* for 1904. Their respective titles are:—"The Formation of the Canterbury Plains," "The Occurrence of *Graucalus melanops* in New Zealand," "Revision of New Zealand Tertiary Brachiopoda," and "Three New Tertiary Shells."

No. 8 of vol. ii. of the zoological section of the *Publications of the University of California* is devoted to the first paper of a memoir of the "Dinoflagellata" of the San Diego district, by Mr. C. A. Cofoid. It appears that investigations carried on during the last few years at the San Diego station have brought to light amid the "plankton" of the Pacific a number of species of flagellate animalcules which cannot be referred to any known genus, and for which the new name Heterodinium is proposed.

Recent issues of the *Proceedings of the Academy of Natural Sciences of Philadelphia* contain papers on the following subjects, viz.:—a collection of birds from British East Africa, by Mr. W. Stone; Hawaiian species of the molluscan genera Endodonta and Opeas, by Messrs. Pilsbry and Vanatta; Pacific Cerithiidæ, by the same authors; and notes on, and descriptions of, Costa Rican Orthopoda, by Prof. Rehn. In the last of these the author describes a very remarkable species of stick-insect of the family Phasmidæ, which is referred to the genus Olcyphides, Griffini, with the name of *O. viridipes*. This species, of which the figure is reproduced, is allied to Westwood's *O. venilia*, of Bogota, but differs in the shorter mesothorax and metathorax, and the much greater elongation of the abdomen and limbs, as well as in details of coloration and other points.

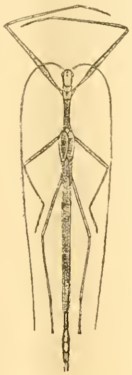

Fig. 1.—*Olcyphides viridipes*, from Costa Rica (½ natural size).

In the November (1905) issue of the *Nature-study Review* Miss A. M. Fielde gives an interesting illustrated account of the communal life-history of ants, primarily intended for the information and guide of those who keep these insects under observation in the cases invented by the author. There are, however, many observations of special interest. Among these is the statement that ants of different species—which always display deadly hostility to one another—can be trained to live together in friendship. Mr. C. W. Wild discusses the study of deciduous trees in winter; while Mr. M. A. Bigelow ridicules the theory that certain groups of plants develop tubers or bulbs in order to escape destruction by animals.

We have received from the author, Prof. F. Eulenburg, of the University of Leipzig, a copy of an article on society and nature ("Gesellschaft und Natur"), reprinted from the *Archiv fur Sozialwissenschaft und Socialpolitik* for 1905. The subject is treated, after some introductory considerations, from the following points of view:—(1) the determination of the objects of science, especially social science; (2) the importance and necessity of social laws; (3) the threefold relation of society to nature; (4) special problems; and (5) the relations of social science to biology and practical politics.

The felted beech coccus, *Cryptococcus fagi*, is the subject of a leaflet, No. 140, issued by the Board of Agriculture and Fisheries. The scale insects are provided with a long sucking tube by which they draw off the sap; they are stationary, and cover themselves with a white waxy secretion. The larvæ also drain the juices of the tree. Although the insects are conspicuous objects on the bark, and are principally found on the main trunk and larger branches, their waxy coverings shelter them effectively, and treatment with such insecticides as paraffin emulsion, Gillander's mixture, or caustic alkali wash must be thorough to prove efficacious.

In the *Indian Forester* (March, 1905) Mr. R. S. Pearson stated that he had obtained satisfactory results in the Panch Mahals, Bombay, in rearing young teak plants by subjecting the seed to a preliminary treatment in pits, in which layers of seed an inch deep were arranged alternately with layers of soil, and the pit was flooded with water every other day until germination commenced. This and other experiments with seed of *Anogeissus latifolia*, described in the November issue, appear to depend upon the maintenance of a regular and sufficient, but not excessive, supply of water. Another fairly successful method consists in subjecting the seed to a slight fire that produces artificially the effects of a light forest fire in a dry teak zone.

Among the contributions to the *Journal of the Royal Horticultural Society* (December, 1905), Dr. M. Cooke writes an article on the fungoid pests of forest trees; Mr. G. S. Boulger, dealing with the preservation of wild plants, adduces a number of specific instances of damage done by ruthless collection; and Mr. W. G. Freeman discusses a few of the important features of the West Indian fruit industry. The method of producing new potatoes out of season from old tubers, as described by Mr. J. J. Powell, is a valuable hint to private gardeners, the essential points being retardation and a variety that keeps well. Fruit growers will be interested in the publication of the report of the committee appointed to inquire into the fruit industry, and in the notes by Mr. T. E. Sedgwick on methods of fruit preserving.

The use of wood-pulp for paper-making was dealt with in a paper read by Mr. M. C. Phillips before the Society of Arts, and published in the Journal of the society last May. A machine for grinding wood into pulp was patented by Keller in 1844, but the modern method of making *mechanical* pulp has developed out of the machine constructed by Henry Voelter in 1858 that not only disintegrated but also assorted the fibre. The mechanical process is largely practised in Norway, Sweden, and Canada, and provides the bulk of journalistic paper. Better paper is produced by chemical processes in which the wood is treated with various chemicals that remove the ligneous and mineral constituents, leaving wood-cellulose. Tilghman (1857), Ekman, and Mitscherlich were the pioneers in this branch of the industry. The paper has been reprinted by the Government of India in connection with the experiment of producing wood-pulp in that country.

A BULLETIN on "The Mineral Constituents of the Soil Solution," by Messrs. F. K. Cameron and J. M. Bell, has been received from the U.S. Department of Agriculture (Division of Soils, Bulletin 30, 1905, pp. 70). This latest publication of the division over which Mr. Whitney presides deals with the problem that has been the subject of so much of the recent work on soils done by the United States Department of Agriculture—the composition of the solution formed by the water in the soil. It is generally recognised now that plants feed on this solution and are incapable of attacking the solid constituents of the soil, so that the composition and mode of origin of this solution must furnish the interpretation of many of the difficulties regarding the relationship of crops to soils. The Bulletin is more of a general discussion and a bibliography than a record of new investigations; it sets out a brief account of most of the work that has been done on such matters as the solubility of the minerals composing the soil, the hydrolysis and similar changes then taking place, adsorption and absorption by finely powdered materials, flocculation, surface reactions, and such other phenomena in the borderland of chemistry and physics as must play a leading part in the reactions going on in the soil. The main thesis of the Bulletin is that the soil materials hydrolyse and form a solution in equilibrium with the portion which remains solid; this position of equilibrium will be continually restored or maintained whenever it is temporarily disturbed, as by the addition of manures or the withdrawal of substances by growing plants. We fail to perceive, however, that all the parade of authorities lend any support to the extraordinary doctrine which the American official soil chemists seem to have adopted as an article of faith—that all soils, whatever their origin or treatment, yield the same soil solution, and therefore possess the same nutritive power. Putting aside this "conclusion," which is brought in at the end, though nothing particular seems to have led up to it, all workers in this field will be glad to possess the Bulletin as a guide to the scattered literature on a difficult subject.

WE have received from Mr. G. Henriksen, of Christiania, a translation of his pamphlet, written in Norwegian, on the iron-ore deposits of Sydvaranger, in Finmarken, Norway. Iron ore occurs in large quantities in gabbro. It consists exclusively of magnetite. The deposits are considered by the author to have been formed by the action of pressure on eruptive rocks.

IT is reported in the *Engineering and Mining Journal* (vol. lxxxi., No. 4) that great development has taken place in gem production in Brazil. Exploration in Minas Geraes has led to discoveries of tourmaline which have furnished red, blue, and green gems, and of beryls which have furnished magnificent blue and green stones. A large quantity of Brazilian amethyst has been obtained from the great geode, the bulk of which was shown at the Düsseldorf Exhibition in 1902.

UP to the present time the manufacture of chilled rolls has remained purely empirical; and a paper by Mr. E. de Loisy in the *Bulletin de la Société d'Encouragement* (vol. cvii., No. 10), describing his researches made to ascertain the scientific rules that should guide the iron-founder, is therefore well worthy of careful attention. For chilled rolls for rolling steel sheets or wire rods the composition sought should be as follows:—carbon, 2·9 to 3; silicon, 0·7 to 0·9; manganese, 0·5 to 1·0; and phosphorus, 0·35 to 0·45. The addition of steel scrap to pig-iron is recommended, but the proportion should not be much above 15 per cent. The author gives a large number of analyses of chilled rolls that have lasted well in the rolling-mill.

AN interesting note on prospecting in the Transbaikalian goldfields has been communicated by Mr. R. Farina to the Institution of Mining and Metallurgy (Bulletin No. 17). The district has long been famous for its gold placers. Platinum and cinnabar are also met with. The gold veins vary greatly in character. Those rich in gold are very porous, friable, and highly oxidised. The other veins are of the hard white quartz type. The best time for prospecting is March and April, when the snows have almost gone. The rocks of the country are chiefly quartz porphyry, granites, andesites, diorites, and gneiss. In a note, in the same Bulletin, on tin in Tringganu, on the east coast of the Malay Peninsula, Mr. C. G. Warnford Lock records the occurrence, in the alluvial tin fields, of monazite and xenotime in pot-holes in the granite beds of the streams.

THE *Journal of the Society of Chemical Industry* (vol. xxv., No. 2) contains an interesting paper by Mr. A. H. Hiorns on the effect of certain elements on the structure of cast iron. He gives a summary of previous researches on the subject, and describes some experiments made by himself with pure cast iron to which various proportions of silicon, manganese, phosphorus, and sulphur were added. He gives illustrations showing the appearance of polished and etched surfaces examined under the microscope. In the discussion, Mr. W. Rosenhain referred to the process of heat tinting in connection with the detection of the presence of phosphorus, and pointed out two very serious difficulties that had to be overcome before satisfactory results could be obtained. These were the difficulty of obtaining the surfaces in a perfectly clean state, and the fact that the actual surface very often did not represent the real structure of the metal, because the very act of polishing tended to spread the softer constituents over the harder, and in all cases produced a definite layer of altered material.

WE have received from Mr. G. T. Beilby a reprint, in pamphlet form, of his presidential address to the Glasgow University Engineering Society, delivered on January 11. In it he discusses, with a thorough mastery of his subject and with conspicuous literary skill, some of the wider aspects of modern power production for industrial purposes, more particularly with reference to the fuel resources of the country. He shows that the annual coal consumption of the United Kingdom is 167 million tons, the various channels of consumption being as follows, in millions of tons:—railways, 13; coasting steamers, 2; factories, 53; mines, 18; iron and steel industries, 28; other metals and minerals, 1; brick-works, potteries, glass-works, and chemical works, 5; gas works, 15; and domestic, 32. Taking the consumption of coal for power purposes at mines and factories as 52 million tons, a saving of some 42 million tons could be realised with time and enterprise. There are in Great Britain steam engines and boilers with a yearly output of at least 5 million horse-power. The coal consumed by these is not less than 5 lb. per indicated horse-power hour, or on the whole 40 million tons. By the use of gas engines and steam turbines the coal consumption might be reduced to 1½ lb. per indicated horse-power hour, or on the whole to 12 million tons. The saving in coal, therefore, is equal to 28 million tons, valued at 9,800,000*l*. The cost of making the change need not exceed 50,000,000*l*., or, if the power is to be delivered as electricity, 60,000,000*l*. The saving in

the coal bill is equivalent to a return of 16·3 per cent. on the higher capital expenditure. In these estimates no credit has been taken for the reduction in working costs which would result from the installation of more efficient plant. In many cases this would amount to as much as the saving on coal.

ACCORDING to the *Teknisk Tidskrift*, the development of the Swedish chemical industries last year was but slight, but the following points may be noticed:—the manufacture of beet sugar has been pushed further north by the opening of a sugar factory at Linköping; the preparation of "peat spirit" has been a subject of wide and searching discussion; the increased uses of acetylene and of acetylene-acetone solutions, and the process of welding with acetylene, have much favoured the carbide industry; the manufacture of paper from wood has improved both quantitatively and qualitatively; great strides are said to have been made in electrochemical industries; much attention has been given to improving methods of producing pig-iron—a number of Gröndal, American, and newer native type combustion furnaces have been built or arranged for; in the manufacture of steel we are told that several innovations and changes have been witnessed, though no official statistics are yet available for comparisons with previous years—but it is to be noted that the Bessemer process is gradually yielding to the Martin method; an experimental electrical steel furnace has been arranged at Nykroppa; many works have introduced Bildt's method of heating boilers with generator gas; suction gas plants, combustion and petrol motors, and steam turbines have risen in popularity.

IN connection with the shortage of rainfall for 1905 in the British Isles, it is interesting to note the state of affairs at the antipodes. With regard to the rainfall of South Australia, Sir Charles Todd states that throughout the whole of the Northern Territory, the interior of the continent, the pastoral country to the northwards, and as far south over the more settled districts as Petersburg, the total rainfall of the year failed to reach the average. The summer season (November, 1904, to March, 1905) was, on the whole, dry all through the settled districts and most of the pastoral country, many stations in the southern areas having only about half the annual supply. The total for the agricultural season (April to October) was, however, generally in excess of the normal fall for this period, from Wilmington and Petersburg southwards, but north of these stations it was rather below the average.

THE construction of magic squares is a recreation which has diverted even such minds as those of Euler and Fermat; with kindred problems it still maintains its popularity. Frost extended the notion to three dimensions, and wrote a paper on "nasik cubes" (*Quart. Journ.*, 1878); in "The Theory of Path Nasiks" (Rugby: Lawrence) Mr. C. Planck has quite recently developed Frost's theory, and given several examples. His method involves the solution of sets of simultaneous linear congruences, and he considers the problem in n dimensions.

IN No. 5, vol. xxii., of the *Astrophysical Journal*, Mr. R. E. Loving, of the Johns Hopkins University, publishes the results of an interesting research concerning the nature and action of the metallic arc in high vacua. Having previously proved that the spectrum was characteristic of the anode only, he employed various metals as anodes in conjunction with the same platinum kathode, and on photographing the more refrangible end of the spectrum found that it was not similar to either the ordinary arc or spark spectra, but was much more like the latter than the former. The relative intensities of the lines obtained did not agree with the spark intensities or with those observed for the same lines in the chromosphere. Mr. Loving gives a tabular statement in which the relative intensities of magnesium, calcium, chromium, manganese, titanium, and iron lines in the ordinary arc and spark, the chromosphere and the arc in vacuum are compared. Other important points regarding the mechanical action of the discharge, the action of a magnetic field, and the luminosity of the anode are dealt with in Mr. Loving's paper. Brief reference might be made here to one peculiar result. The violent kathode discharge was found to have a marked deteriorating action on the glass of the tube. After being used for several days the glass was found to crack much more readily when put into a flame, and the fragments were so friable that they could easily be broken between the fingers.

MR. JOHN GOLDING AND DR. FEILMANN direct attention to a peculiar mealy flavour which occasionally develops in milk (*Journ. Soc. of Chem. Industry*, December 30, 1905). Experiments showed that copper is acted upon by milk, especially in the presence of air, and that small quantities go into solution in the milk (from 1 part to more than 100 parts per million). Fresh milk when thus contaminated is very liable to the development of a peculiar mealy flavour in sixteen to eighteen hours. This flavour seems to be due in part to the development of micro-organisms in the presence of copper, which both checks the development of the lactic organisms and plays a more direct part in the actual development of the flavour.

COLONEL FIRTH AND DR. MACFADYEN contribute to the *Journal of the Royal Sanitary Institute* (xxvii., No. 1) a record of experiments made on behalf of the Disinfectant Standardisation Committee from which they consider that the "drop" method of Messrs. Rideal and Walker is the most practical and accurate method yet devised for the testing and comparison of disinfectants, and make some valuable suggestions for carrying it out. Profs. Kenwood and Hewlett also contribute a paper on the standardisation of disinfectants, in which they show the variations which may obtain in practice and the modifying effect of organic matter on germicidal power, and urge that a large margin of safety should be allowed for all disinfectants.

THE *Journal of the Röntgen Society* (December, 1905) contains an interesting paper by Mr. Butler Burke on the action of radium and other bodies on gelatin, and the production of the so-called "radiobes," which have some likeness to micro-organisms. At first these look like mere air-bubbles, but in course of time they expand or grow, appear to contain a nuclear structure, but in the course of a fortnight or so begin to break up, and later on disappear. They are also soluble in warm water and varnish at a temperature of 35° C. Mr. Burke expresses the opinion that they are on the border-line between crystalline and organic bodies, that they cannot properly be called living, but correspond possibly to some simple form of life that existed in a far distant age.

UNDER the title of "La Fin de la Matière," Prof. H. Poincaré gives in the *Athenaeum* for February 17 a brief *résumé* of recent views of the ultimate nature of matter. The essential purpose of Prof. Poincaré's article is to define how far the idea of mass or inertia has been compromised by the results of Abraham and Kaufmann, by the speculations of Lorentz, and by the doctrine of

electrons. Prof. Poincaré is careful to emphasise the assumptions on which recent views are based, but if the assumptions are correct the final result consists in stripping from matter the attribute of mass by which it is usually defined. Mass appears purely as the result of electrical action, or, in Prof. Poincaré's own striking words, "dans ce système il n'y a pas de vraie matière, il n'y a plus que des trous dans l'éther."

SOME time ago Prof. Nernst described a simple form of torsion balance capable of measuring weights of a few milligrams with an accuracy of 0·001 milligram. In the current number of the *Berichte* Mr. H. v. Wartenberg gives an interesting application of this instrument to the determination of the molecular weight of silver vapour. The method used was a modification of the well known apparatus due to Victor Meyer, the vessel being made of iridium, coated internally with a mixture of the oxides of yttrium and zirconium. This iridium vessel was heated in an electric furnace to about 2000° C., the weight of silver used in each experiment varying from 0·905 to 0·322 milligram. The values obtained for the molecular weight of the silver were between 107 and 147, indicating that silver is monatomic.

MESSRS. DAWBARN AND WARD, LTD., have published in their "Home Worker's" series a little book by Mr. Joseph E. Dangerfield on "Brass and Iron Founding." The price is 1*s.* 6*d.* net.

THE "Swincam" camera stand enables a camera to be fixed on the tripod in almost any position, so that photographs can be taken in situations which present insurmountable difficulties with ordinary stands. A revised pamphlet showing some of the possibilities and performances of this speciality in tripod stands has been issued by the maker, Mr. W. Butler, Southport.

MESSRS. WHITTAKER AND CO. have published a second edition of Mr. S. R. Bottone's "Radiography and the 'X' Rays." The book was reviewed in our issue of July 28, 1898 (vol. lviii. p. 292); and it is only necessary to say here that recent improvements in Röntgen-ray apparatus, and interesting matter connected with the therapeutic effects of the rays, are dealt with in the new edition.

OUR ASTRONOMICAL COLUMN.

COMET 1906*a*.—The following is taken from a continuation of the daily ephemeris for comet 1906*a* (Brooks), published by Herr M. Ebell in No. 4075 of the *Astronomische Nachrichten*:—

Ephemeris 12h. M.T. Berlin.

1906	α (true) h. m. s.	δ (true) ° ′	log *r*	log Δ	Brightness
Feb. 22	6 45 35	+78 30	0·2047	0·0024	0·82
24	6 21 29	+75 12	0·2094	0·0150	0·76
26	6 7 28	+71 59	0·2140	0·0288	0·69
28	5 58 38	+68 55	0·2187	0·0435	0·64
Mar. 2	5 52 47	+66 1	0·2234	0·0589	0·58
4	5 48 50	+63 19	0·2282	0·0748	0·53

It will be seen from the above that the comet is now travelling rapidly down the constellation Camelus towards Perseus, and is becoming much fainter.

A set of parabolic elements of the orbit of this object has been computed by M. E. Maubant, and appears in No. 6 (1906) of the *Comptes rendus*.

COMET 1905*c*.—Photographs of Giacobini's comet (1905*c*) obtained at Greenwich early in January showed that the magnitude was about 3·0, and that this object had a tail about 2° in length.

A note in the February number of the *Bulletin de la Société astronomique de France* quotes M. Giacobini, who, in a letter to a correspondent, stated that the comet was visible to the naked eye during the whole week preceding January 9, and that it then had a tail about 1° in length, the position angle of which was 45°. The nucleus was estimated as being of the second or third magnitude. The nearest approaches of this object to the earth took place on January 6 and February 2, the respective distances being 1·102 and 1·150 astronomical units. Its distance from the sun at perihelion was 0·2154 unit.

THE APPARENT ENLARGEMENT OF THE MOON AT THE HORIZON.—In the *Archives de Psychologie* (vol. v., No. 18, October, 1905) M. Ed. Claparède publishes an interesting paper on the causes which produce the impression that the sun, moon, and other celestial bodies are larger when near to the horizon than when seen at the zenith.

After discussing a number of theories propounded by previous writers on this subject, from Aristotle onwards, he examines several possible causes, and recounts the results of various experiments he has made whilst considering the matter.

Finally, he arrives at the conclusion that when we see the moon, or sun, at the horizon, we are surprised into believing it to belong to things terrestrial—to come into the class of objects which are by far of the greatest interest to us. As such we notice it with much greater attention,

and for this reason overestimate its size. When at the zenith the moon is of little interest in comparison with the terrestrial objects which belong to our daily life, and we therefore think of it as relatively unimportant; consequently we underestimate its size. This correlation of importance and size is always common, and, as an illustration of it, M. Claparède quotes the fact that boys are always astonished when they learn for the first time that Napoleon was below the average height.

M. Claparède used the illustration we reproduce, in his experiments with individuals. Covering one of the moons shown, he asked his subjects to draw the other one the same size, and then asked them to draw the second whilst the first was covered. Of twenty couples of drawings thus obtained, from thirteen subjects of all ages, the moon at the horizon was shown as the greater on fourteen, as equal on five, and as less on one. The greatest difference was shown on two drawings by the same boy, where the moon was 9 mm. (horizon) and 4·5 mm. (raised) respectively, the actual diameter on the copy being 4·5 mm.

M. Claparède's paper may be obtained, as a separate brochure, from MM. Kündig et Fils, Geneva, price 1 franc.

MAGNETIC OBSERVATIONS DURING THE TOTAL ECLIPSE OF THE SUN.—We have received from Father P. Cirera, of the l'Ebre Observatory, an extract from the *Comptes rendus* giving an account of the magnetic records obtained at

that observatory during the total solar eclipse of August 30, 1905, and the days immediately preceding and following it.

Extraordinary deviations from the normal diurnal curves were registered in all three elements, and these are plainly shown on the photographic copy of the records which accompanies Father Cirera's communication.

OBSERVATIONS OF JUPITER.—Major Molesworth's report of his observations of Jupiter, made at Trincomali, Ceylon, during 1904–5, appears in No. 3, vol. lxvi., of the *Monthly Notices R.A.S.*, and records the times of rotation of, and the changes in, most of the Jovian features.

One especially remarkable observation was that the following and preceding ends of the large mass of dark matter, known as the Great S. Tropical Dark Area, appeared, on comparing the observations, to have crossed the whole Red Spot bay simultaneously. As it seems impossible that there could be any such instantaneous transference of material, Major Molesworth explains the phenomenon by the suggestion that the movement of the dark area into the belt following the bay caused the extrusion of an equal amount of dark material from the belt preceding the bay.

GRANULATIONS ON THE SOLAR SURFACE.[1]

AN interesting research which promises fair to lead us to an increased knowledge concerning the nature of the sun's photosphere has recently been instituted by Prof. Hansky at the Pulkowa Observatory. On examining the splendid collection of photographs of the solar surface obtained by Prof. Janssen at Meudon, Prof. Hansky was not able to satisfy himself that the whole of the *réseau* seen on the negative was actually of solar origin; it seemed probable that some parts of it were produced by waves in our atmosphere, and on no two consecutive negatives, nor even on two taken simultaneously, could the same granules be recognised. For this reason he attacked the problem at Pulkowa, bringing into operation the astrographic telescope in order to obtain photographs on a large scale.

The solar image at the focus of this instrument has a diameter of 3 cm., which by the use of a concave lens was increased to about 54 cm. (*i.e.* 21·3 inches). With this apparatus numerous photographs were obtained during May and June, 1905, and showed many of the finer details of the granulations which cover the solar surface; but even on this scale it was impossible to recognise the same features on successive photographs. A further improvement was then made, so that the intervals between the exposures might be appreciably shortened—in no case had it been less than five minutes—and with the new arrangement adapted to the astrograph it became possible to take eight consecutive photographs with intervals of fifteen to thirty seconds' duration. These showed the changes taking place in the sizes and relative positions of the granules very plainly, and from them the author has chosen six for reproduction in his circular. Fig. 1 is a copy of one of these reproductions, and shows the general nature of the photographs which Prof. Hansky is obtaining, and from which he hopes to derive valuable results. The scale is such that the solar diameter would measure about 0·6 m., or 23·5 inches. The large black portions represent parts of sun-spots which came within the region photographed.

Although on this scale obvious changes in the size and arrangement of the granules took place in twenty-five seconds, it was impossible to measure their magnitude, so Prof. Hansky intensified the photographs by successive copying, and finally obtained positives showing portions of the disc on such a scale that the length of the solar diameter would be about 6 m. (19·7 feet), that is to say, 1 mm. $=0''\cdot32$, or 233 km. on the solar surface.

An examination of these positives showed that the primary desideratum had been attained; the same granules were recognisable on successive photographs, and the scale was large enough to enable measurements of the granules themselves and of their movements to be made. The displacements were measured with the stereo-comparator, and were referred to a neighbouring small spot, movement towards the spot being indicated by the negative, and away from the spot by the positive, sign. The diameter of the actual sun was taken as 1,400,000 km., and on June 21 this gave $1''=740$ km. The mean variation of any two settings on the same object was $\pm 0''\cdot 12$, and the probable error for the relative displacement $\pm 0''\cdot 10$.

The displacements of the granules during the twenty-five seconds which elapsed between two successive photographs taken on June 25 were very diverse. In that interval five of the granules had moved $-0''\cdot 9$, $-0''\cdot 55$, $-0''\cdot 77$, $-0''\cdot 48$,

FIG. 1.—June 25, 1905, 5h. 6m. 20s.

and $-0''\cdot 80$ respectively, which in the mean gave $-0''\cdot 70$, or -518 km., *i.e.* about -21 km. per second. Another group gave -38 km. per second, whilst for a third the comparatively low velocity of -14 km. per second was recorded.

Comparisons of other photographs showed that some granules were moving away from the spot with various velocities, and, as shown by the following figures, it appeared that the periodic movement of the granules materially affected the size of the spot. The diameter of the spot is given for different times on June 25:—

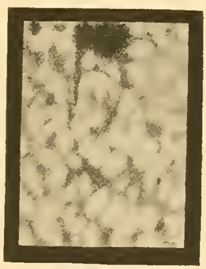

FIG. 2.—June 25, 1905, 4h. 17m. 15s.

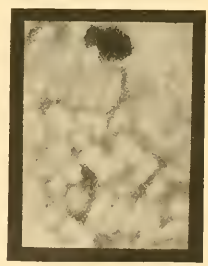

FIG. 3.—June 25, 1905, 4h. 17m. 40s.

4h. 17m. 15s., $2''\cdot 64$; 4h. 17m. 40s., $2''\cdot 25$; 5h. 3m. 15s., $3''\cdot 03$; 5h. 4m. 15s., $1''\cdot 35$; 5h. 5m. 50s., $2''\cdot 70$; 5h. 6m. 20s., $2''\cdot 88$.

On consecutive photographs taken with an interval of one minute the same granulation was recognised with difficulty, whilst with a three-minute interval the whole *réseau* was practically re-arranged beyond recognition, although in one or two cases it was possible to trace a granule after this interval, and in two cases it was remarked that gemination had taken place.

The dimensions of the granules varied greatly between

[1] "Photographies de la Granulation solaire faites à Poulkowa." By A. Hansky.

670 km. and 2000 km., the mean diameter being 1″·9, or about 1400 km. Figs. 2 and 3 illustrate the type of photograph on which the measures were made. These were taken with an interval of twenty-five seconds, and even a cursory glance will show that during that time the arrangement and forms of the granules have altered considerably; on this scale the diameter of the sun would be about 3 metres.

It seems probable that these researches will lead to most important conclusions concerning the nature and the periodicity of the changes in the granules themselves, their influence on the solar spots and faculæ, and, in general, to the resolution of many outstanding problems concerning the nature and action of the photosphere, which are at present unsolved. Prof. Hansky intends, therefore, to pursue this line of research, but, as he points out, it will cnly be during the comparatively rare moments of atmospheric calm, and with such a powerful equipment as he now possesses, that fruitful results are likely to be obtained. In any case, he is to be warmly congratulated upon those he has already published.

W. E. ROLSTON.

PRACTICAL SCIENCE FOR SCHOOLS.[1]

PROF. PERRY said that in the early days of the society, when he had the honour of acting as a secretary, and when Guthrie and Foster, Kelvin and Fitzgerald were presidents, no presidential addresses were delivered, and he questioned whether we were not overdoing the business of requiring general addresses, which must almost always have as their theme the progress of science. Seldom did we find in such addresses new accounts of important original work, and he felt the inappropriateness of such an address in speaking before a society the Proceedings of which were more intense with original work of the best kind than any other society known to him with the exception of the Royal Society. He thought that every young reader of a paper before a scientific society made the mistake of assuming that his audience knew a great deal of the subject so familiar to himself, and hence his paper was not understood. Writers of books on physics assume their readers to be all truly logical students; they use words properly in a technical sense, and forget that many of their readers may use them in the newspaper writer's sense. For example, take the expression "adiabatic expansion." There are people who insist on finding that Rankine, Maxwell, and all others of our most exact writers are not only inconsistent with one another in the use of the expression, but that each is inconsistent with himself. If a portion of fluid expands slowly without gain or loss of heat, we know the way in which its p, v, and t alter as it changes state; this was originally called "adiabatic expansion," and the term has become a technical term for that kind of alteration of p, v, and t, however it may occur. Steam or air may be throttled through a non-conducting reducing valve, but the expansion is not adiabatic, although there is no gain or loss of heat. Steam or air passing along a pipe with friction, if it can only be made to lose heat through the metal of the pipe at exactly the proper rate at every place, is expanding adiabatically. When it is assumed that steam or air flows without friction from a vessel through an orifice, it is said that the expansion is adiabatic although it is rapid.

Referring to the teaching of physics to students entering upon the engineering profession, the president remarked that such teaching was nearly always slipshod. Many men enter a science college at the age of eighteen or more, knowing nothing of physical science. In the case of a great percentage of such men, it is impossible that they should acquire the scientific habit of thought. It is because so much of this kind of material is dealt with that much of our teaching is slipshod. Every pupil entering a science college ought to have been experimenting and working graphically and numerically on physical science problems from a very early age, and then our science classes would deal with them in a scientific way. The causes of the unfitness of the average student are two: one that his instincts and habits of thought were not trained from early youth; the other that his teachers in science colleges have absurd and uninteresting courses of study for him. In physics we are dealing with ideas which are not familiar to young students, ideas which can only become familiar in the laboratory. For example, such a simple mathematical idea as that of a decimal cannot be given in elementary schools in less than five or six years, whereas one week of weighing and measuring would give young children familiarity and clear ideas about decimals. Numerous examples could be given to prove that the principles of physics cannot be understood unless there has been early experimental training, and this is the reason why the professors of science in colleges of university rank and the professors in technical colleges obtain such poor reward for their labour. Referring to the many hundreds who every year take science degrees at the universities, and the thousands who pass the London University matriculation examination, Prof. Perry remarked that if that was the standard of excellence of those present, his address could serve no useful purpose. Nothing ought to be compulsory in schools except the study of English and of natural science. The object of a matriculation examination is to test whether a student entering a college will be able to benefit by the course of study there. The only language which ought to be compulsory in the science department of a university is English. A professor of science ought to be allowed to teach his students in the way that seems best to him, and he should examine his students himself. Hedge him round with rules and regulations framed by boards of studies; tie him down to a syllabus, and the work he will do might be much better, certainly much more cheaply, done by a grinder at low wages. There is no one general elementary course in physics which all students ought to take; neither by their previous training nor from the uses which they will make of the principles of physics are they fit to be taught together. What is wanted is more classes, more rooms, and more teachers.

[1] Abstract of the presidential address delivered before the Physical Society on February 9, by Prof. J. Perry, F.R.S.

THE NEW ORLEANS MEETING OF THE AMERICAN ASSOCIATION.

THE New Orleans meeting of the American Association for the Advancement of Science, as stated in our issue for January 25 (p. 303), began on December 29, 1905, and continued for five days. At a meeting of the general committee it was decided to hold a special summer meeting at Ithaca, New York, to close on or before July 3, 1906, and an ordinary winter meeting in New York City to begin on December 27, 1906. The presidential and vice-presidential addresses will be omitted at the summer meeting and given at the winter meeting. The officers elected at the New Orleans meeting will, therefore, hold office until the close of the New York meeting. Chicago was recommended as the place of the winter meeting of 1907.

The following officers were elected for the Ithaca and New York meetings:—President: Dr. W. H. Welch, Baltimore, Md. Presidents of sections: A, Dr. Edward Kasner, New York City; B, Prof. W. C. Sabine, Cambridge, Mass.; C, Mr. Clifford Richardson, New York City; D, Mr. W. R. Warner, Cleveland, O.; E, Prof. A. C. Lane, Lansing, Mich.; F, Prof. E. G. Conklin, Philadelphia, Pa.; G, Dr. D. T. MacDougall, Washington, D.C.; H, Prof. Hugo Münsterberg, Cambridge, Mass.; I, Mr. Chas. A. Conant, New York City; K, Dr. Simon Flexner, New York City. General secretary: Mr. John F. Hayford, Washington, D.C. Secretary of council: President F. W. McNair, Houghton, Mich.

The following resolutions were adopted by the association:—(1) That the association instructs its president and secretary to communicate to the president of the Senate and to the speaker of the House of Representatives of the United States its strong conviction that Niagara Falls should be preserved as a natural wonder, and further expressing the earnest hope that the congress now in session will take prompt and energetic action looking toward an international consideration of the impending danger to Niagara Falls. (2) *An Appalachian Forest Reserve.*—That the association again respectfully calls attention to the rapid rate at which the forests of the

Appalachian Mountain region are being destroyed, and to the fact that, as a result of such destruction, the streams tributary to the Mississippi, as well as those flowing into the South Atlantic, are becoming continuously more irregular in their flow, and hence of less value for navigation and power purposes. (3) That the association respectfully petitions the Congress of the United States to make such provision as may be necessary for the protection of these mountain forests.

The following grants were made at this meeting of the association:—40*l.* to Messrs. Parsons, Kinnicutt, and Venable to assist in the publication of Prof. Parsons's "Bibliography of Beryllium," and 20*l.* to "The Concilium Bibliographicum Zoologicum."

The committee on electrochemistry reported as follows:—A study has been made of the behaviour of platinum and iridium in chlorine water and in dilute hydrochloric acid. Smooth platinum foil brought about no evolution of gas even after standing 168 hours in chlorine water. In precisely similar circumstances an iridium foil caused an evolution of 44·4 [? c.c.] of gas, 55 per cent. of which was oxygen. The oxygen results from the reaction

$$Cl_2+H_2O=2HCl+O,$$

while the chlorine came from the solution, the original vapour pressure having been about half an atmosphere. This series of experiments showed that iridium was a more powerful catalytic agent than platinum. A number of electrolytic experiments were made with hydrochloric acid of different concentrations. In all cases more oxygen was evolved from the iridium anode than from the platinum anode. The question as to the final equilibrium is still in doubt.

The Popular Conception of the Scientific Man at the Present Day.[1]

The traditional scientific man has disappeared almost as completely as the traditional Yankee of the stage. The change came gradually, but the proof that it had come was brought before us suddenly. In 1902 there was called in New York a meeting of those who were designated by the picturesque expression captains of industry. To that meeting representatives of science were invited, not as lions to be stared at, but to sit with the leaders of the industrial and commercial world as representatives of science, and not only of applied science, but of pure science. As the captains of industry were supposed to be men of force in organising and to have a keen insight into men and things, we had a right to feel that science was honoured, perhaps not more than ever before, but for a reason for which it had not been honoured before in the United States. The fact that since that date the reputation of some of the captains of industry has suffered an eclipse does not alter the fact that to be considered a captain of industry was, in the eyes of the public, enviable. The conception of a scientific man as a captain of industry means simply the acknowledgment that science has a practical relation to the world, and that fortunately the public have advanced far enough to see, although perhaps somewhat dimly, that pure science sooner or later develops into applied science. The leaders of science are to be placed in the class of organisers, managers of a sort of scientific trust. This is science up to date, and the public are right when they regard science as an organisation. But they are only partly right. There is a good deal more than that in science, and, although good managers and directors are necessary, it is true that the power of organising and the power of investigating are two different things, and often exist in inverse ratio to each other, and it is the latter which is at the basis of science. An organiser is of no use until there is something to organise, and the materials on which the organiser in science must work are not made by machinery, but by the brains of individual workers, and it is important that they should be placed under the most favourable conditions for work. If hitherto there has been perhaps too little organisation, there is a danger that in the future there may be too much. In a mill many men are doing the same kind of work, but in science one man should not duplicate the work of another. The object of organisation in the one case is to secure uniformity of product, in the other to encourage diversity of work.

The ways in which the public may aid scientific men are directly by endowments for paying salaries and indirectly by providing properly equipped laboratories and other necessary equipment, and especially for paying for the services of assistants. Both forms of help are necessary, for a man capable of managing and getting the greatest amount of good work out of a well equipped establishment deserves more than a meagre salary. On the other hand, those with what appears to be a respectable salary may have to spend a good part of it to make good the deficiencies in their equipment. In deciding whether a man is well paid or not, it is necessary to ask not only what salary he receives, but what are the means of work provided for him. It is not my intention here to direct attention to the special ways in which scientific establishments would be benefited by gifts from the public nor to discuss the question what is a proper salary for a scientific man. The latter depends upon too many complicated conditions, and cannot be separated from the more general question of what those in equally important positions in other walks of life are paid. The question of proper equipment, including the question of assistants, has already been brought before the public on a good many occasions and in a good many ways, and a good deal has been given in recent years, although by no means enough.

If, as it appears, the public have reached a better conception of the position of the scientific man and of his pecuniary needs, it may be added that he has the right to hope that he can appeal to the public not only for pecuniary, but for moral support, for, in many cases, the public are the final arbiters where differences arise, and unfavourable conditions often disappear quickly as soon as it is felt that one side or the other is backed by public opinion. It may, therefore, be well to state somewhat explicitly some of the conditions which are unfavourable to the progress of science in the United States or which tend to retard it. Here it is not so much a question of money as of a just appreciation of the true position of scientific men in their relation to those for whom their work is undertaken. That work, using a rough classification, may be considered as that done in technical and commercial concerns, that done for the Government, and that done in universities, including under that general term all colleges, scientific schools, and similar institutions which have a permanent endowment of some kind.

[1] From the address of Prof. W. G. Farlow, president of the Association.

The Relation of Mechanics to Physics.[1]

We find the physicists of the beginning of the nineteenth century still very strongly attached to the idea that all natural phenomena not only may, but must, be explained on the basis of Newton's laws[2] by central forces acting instantaneously at a distance. Newton's mechanics had done such admirable service in astronomy that it had come to be regarded as the only possible means of describing and discussing the actions of nature. The gradual abandonment of this position and the change to the modern view, according to which all actions in nature are transmitted through a continuous medium and require time for their transmission, was accomplished only after a long struggle that occupied the greater part of the nineteenth century.

It is well known how the ideas of Faraday, of Maxwell, of Hertz, gradually gained ascendency over the older views and led to the abandonment of the idea of central forces acting instantaneously at a distance, in almost all branches of physics except in the theory of gravitation. It is also known that Maxwell, by a brilliant analysis, succeeded in establishing the connection between his electromagnetic theory and the analytical mechanics of Lagrange. Thus, at the end of the nineteenth century we find a general attitude toward physical phenomena essentially different from that prevailing at the end of the eighteenth century.

With the rise of the electron theory in the course of the last twenty-five years a new element has been introduced

[1] From the address of Prof. Alexander Ziwet, president of Section A, Mathematics and Astronomy.

[2] See, however, Laplace, "Mécanique Céleste," livre i., chap. vi. ("Œuvres," vol. i., 1878, pp. 74-79), a passage to which E. and F. Cosserat have recently directed attention.

into this development, an element which seems destined to affect very radically, not only our interpretation of physical phenomena, but also our general views about the principles of theoretical mechanics.

There seem to be two things underlying all the phenomena in the physical world—the ether and matter. To attain the unification of physical science, shall we consider the ether as a particular kind of matter? Or shall matter be interpreted electromagnetically? The older mechanics dealt exclusively with matter; and when it first became necessary to introduce the ether, this new medium was often endowed with properties very much like those of matter. The hydrodynamic analogy by which the apparent mass of the moving charge was interpreted illustrates this tendency. The physics of the ether has, however, reached so full a development that the properties of the ether are now known far more definitely than those of matter. These properties are contained implicitly in the fundamental equations of Maxwell and Hertz which in their essential features are adopted in the electron theory of Lorentz.

It is now pretty generally recognised that Newton's "laws of motion," including his definition of "force," are not unalterable laws of thought, but merely arbitrary postulates assumed for the purpose of interpreting natural phenomena in the most simple and adequate manner. Unfortunately, nature is not very simple. "As the eye of the night-owl is to the light of the sun, so is our mind to the most common phenomena of nature," says Aristotle. And if since Newton's time we have made some progress in the knowledge of physics, it is but reasonable to conclude that the postulates which appeared most simple and adequate two hundred years ago cannot be regarded as such at the present time.

This does not mean, of course, that the mechanics of Newton has lost its value. The case is somewhat parallel to that of the postulates of geometry. Just as the abandonment of one or the other of the postulates of Euclidean geometry leads to a more general geometry which contains the old geometry as a particular, or limiting, case, so the abandonment or generalisation of some of the postulates of the older mechanics must lead to a more general mechanics. The creation of such a generalised mechanics is a task for the immediate future. It is perhaps too early to say at present what form this new non-Newtonian mechanics will ultimately assume. Generalisation is always possible in a variety of ways. In the present case, the object should be to arrive at a mechanics, on the one hand sufficiently general for the electron theory, on the other such as to include the Newtonian mechanics as a special case.

After the searching criticism to which Poincaré, especially in his St. Louis address,[1] in 1904, has subjected the foundations of mechanics and mathematical physics, almost the only one of the fundamental principles that appears to remain intact is the principle of least action. It seems, therefore, natural to take this principle as the starting point for a common foundation of mathematical physics and of a generalised mechanics, but with a broader definition of "action," or what amounts to the same, with a generalised conception of "mass" so as to make the latter a function of the velocity.

The Partition of Energy.[2]

The general theorem which I wish to discuss may be stated by saying that the kinetic energy of the body is so distributed among the degrees of freedom, by which the state of the body as a dynamical system is described, that an equal share is, on the average, allotted to each degree of freedom of each type of molecule.

The questions which have always been raised about this important theorem of the kinetic theory at once come to our minds. First, is the theorem true, or rather, does it state what would be true for an ideal system of particles moving freely within a containing vessel? second, is the proof of the theorem impeccable? third, is there any experimental evidence that it applies to real bodies?

[1] "Bulletin des sciences mathématiques" (2), 28, pp. 302–324; English translation in the *Bulletin of the American Mathematical Society*, vol. xiii., February, 1906.

[2] From the address of Prof. W. F. Magie, president of Section B, Physics.

I would remark about the first question that the theorem is so distinguished by its simplicity, and by its aspect as a sort of unifying principle in nature, that few men can set it fairly before their minds without at least desiring to believe it true. Most of those who have recognised that Maxwell's original demonstration was not flawless are still convinced of the truth of his conclusion, or at least believe his conclusion to be so probable as to make it worth while to try for a more accurate demonstration. Their state of mind is like that of Clausius and of Lord Kelvin, when they perceived that Carnot's theorem respecting the efficiency of a reversible engine could not be proved in the way in which Carnot tried to prove it.

With respect to the second question, it was very soon pointed out that Maxwell had made in his proof an assumption that could not be justified by immediate inspection, and which was itself in need of demonstration or of avoidance. The later demonstrations of Maxwell and Boltzmann have been likewise subjected to criticism, and can be shown to involve assumptions that will not be granted on inspection. The difficulties that arise in these proofs come from the necessity of applying in them the calculus of probabilities, and centre around the question of the legitimacy of the application of that calculus. It is commonly agreed that Maxwell and Boltzmann have assumed a condition of the system of moving particles, as a requisite for the application of the calculus of probabilities, which is contradicted by many systems of which we have certain knowledge, and cannot without proof be admitted as likely to obtain in other systems, about which less is known. In the method employed by Jeans the application of the calculus of probabilities is made in a different manner, and does not necessitate the introduction of the hypothesis of Maxwell and Boltzmann. It seems to me that, in this last form of the theory, the difficulties which have environed the subject have at last been mastered.

In respect to the third question, that concerning the experimental evidence for the truth of the theorem, it is well known that, in general, Boyle's law follows as a consequence of the general principles of the kinetic theory, that Gay-Lussac's law is an immediate consequence of a relation plausibly assumed between temperature and the kinetic energy of the molecule, that the motion of the radiometer and the laws of transpiration and many other properties of gases can be deduced from the general theory, and, in particular, that Avogadro's law follows from the simplest form of the theorem of equipartition. But further proof of this theorem in its general form is still needed. Such proof as we have will be discussed in this address.

Considering the bearing of the relations that have been adduced upon the general question of the equipartition of energy, it seems to me that their general consistency with that principle, especially the way in which the heat capacities of the organic compounds can be portioned out among the atoms by means of simple assumptions about their degrees of freedom, does afford some confirmation of the principle. Mere chance can hardly account for so large a number of successful coincidences.

The Sanitary Value of a Water Analysis.[1]

Though much valuable information can be obtained from the careful study of the nitrogen content of a water, the water analyst does not depend alone upon these factors in forming an opinion as to the source of the organic matter, and turns to other chemical as well as to bacterial data to substantiate or modify the opinion thus formed. From the chemical point of view the most important of these data is the combined chlorine that a water contains. This is due to the fact that though chloride of sodium occurs in rain-water, especially near the sea, and in small amounts is found in all soils, it is a characteristic constituent of sewage, the animal body expelling the same amount of salt as it absorbs.

A careful study of the amount of combined chlorine in normal waters, made by Prof. Thomas M. Drown, showed that in Massachusetts, where salt-bearing strata do not occur, the amount of chlorine in a surface water depended on its distance from the sea, and that for Massachusetts

[1] From the address of Prof. Leonhard P. Kinnicutt, president of Section C, Chemistry.

it was possible to establish normal chlorine, or, as they are commonly called, iso-chlor lines.

The work begun by Prof. Drown has been carried on by other investigators, and to-day the iso-chlor lines for all the New England States and New York and New Jersey have been determined. The result of this work is that the amount of chlorine occurring in the surface waters of the above named States gives most valuable information. Chlorine above the normal of the region shows pollution. It does not indicate whether the pollution is direct or indirect, but does show that sewage, from which the organic matter and the germs of disease may or may not have been removed by filtration through soil, has had access to the water. Chlorine above the normal is, therefore, always a suspicious sign which must be investigated. I know that it is claimed that in many of the western States, owing to geological conditions, very little information can be obtained from the determination of chlorine. I believe, however, more careful and thorough work is necessary to prove that such is the case, and that further investigation may show that though it is impossible to construct iso chlor lines running through the State, the normal chlorine of different localities in a State can often be determined.

Another factor that is often used in the attempt to decide whether or not a water contains an excessive amount of organic matter is the oxygen consumed. The oxygen consumed is not, however, a measure of the organic matter in a water, but only a measure of the amount of mineral reducing salts plus a certain amount of the organic matter, the amount depending on the method of determination used. It gives, in my opinion, very little information as to the character of the organic matter, and is only valuable when different surface waters are to be compared with each other, or when used in filtration experiments.

The same may be said as regards colour, turbidity, and the amount of mineral matter that a surface water contains, that, though of essential importance in deciding on the value of a normal water as a potable water, they give little information as to pollution.

In the early days of bacteriology it was claimed that the final criterion as to pollution of a water would be furnished by aid of that science, and though this hope has not been fulfilled, the information that can be gained by a bacterial analysis is often of the highest importance. It not only aids in the interpretation of the chemical data, but may of itself show, almost without question, that a given water is polluted, for though attempts to isolate special pathogenic germs have generally failed, even in waters known to contain these forms, characteristic sewage forms, like the colon bacillus, can be isolated if they occur in any number in a water. Occurrence of numerous characteristic sewage bacteria can point only to one thing, pollution, and if such forms are found there is no question that the water receives sewage drainage. Bacteriology, however, cannot determine, except very roughly, the amount of pollution or the present condition of the polluting matter, nor does it give but very little, if any, information as to past pollution. If the pollution is recent and of any considerable amount, a careful bacterial examination will show the fact, and probably better and more convincingly than any chemical analysis. If the pollution is more remote, more information can, as a rule, be drawn from chemical than from bacterial data. If the polluting matter has filtered through the soil before entering the water, bacterial work will not indicate the fact.

As a general statement, it may be said that a bacterial analysis, while giving information as regards recent and continuous pollution, gives no information as to the past history of a water, and in this respect differs from a sanitary chemical analysis.

To form a judgment as to the wholesomeness of a water, the data of a sanitary water analysis, the source of the water, whether surface, ground, or artesian, must be known; a survey, even of a surface water, though it may show whether or not the water is polluted, does not give information regarding the amount or condition of the polluting matter; with ground and artesian waters it often gives very little information, and an opinion regarding the character of such waters must, as a rule, depend on the sanitary analysis.

The Generic Concept in the Classification of the Flowering Plants.[1]

The difficulties of classifying plants in a really natural and logical way are somewhat increased by the involuntary and well-nigh necessary admission of a certain historic element into our systems. There is another source of this artificiality, besides the temptation to allow poor genera to stand, on the ground of long usage. The relation of a genus to its name is a matter which exerts no small influence in this regard. The attempt to determine which of several names is to be retained for a given genus constantly forces us to consider the historic basis on which the genus rests, and to attach its name to some species or group of species to which it was first applied, to determine, in other words, what was the type of the genus, and to maintain the genus in such a way that it may always be true to its type. While sympathising to a considerable extent with those botanists who desire to place our nomenclature upon a more secure basis by attaching the names to recognised types, I feel that the methods employed will have to be very cautiously applied, or they will tend greatly to increase the artificial element in our system. The historic type is not a natural thing; it is merely that particular form of plant life which was, often quite by accident, first discovered and, therefore, first received the name which it bears. Later discoveries often show that this first species of a genus is by no means of a typical, or, as one may say, central character. It is often quite peripheral, perhaps even an aberrant or outlying member of the group to which it belongs. However important the historic type may be in nomenclature, it is obvious that it is of no particular significance in classification, and any employment of the type method in the determination of proper names must not on any account be permitted to exercise any influence in classification. The word type itself is decidedly unfortunate as thus applied to what is often very far from being typical. In this as in some other phases of taxonomy it is of the greatest importance to keep it clearly in mind that nomenclature, although very necessary to classification, is a thing wholly apart from the classification itself. It is, furthermore, quite evident that nomenclature should be subservient to classification, and that the clearness and accuracy of classification should never be sacrificed in order to give beauty or symmetry to any system of nomenclature.

The limitation of genera has always in the past rested on individual judgment, and it must continue to do so in the future. Although the genera of the flowering plants have now been scientifically studied for about two centuries, there is at present in America, at least, a degree of diversity in their interpretation which is rather discouraging. It is disheartening because it is impossible to see in it any real progress toward a well rounded and satisfying system, which will win the confidence of the professional botanist, give uniform training to the student, and command the respect of our colleagues in other branches of science. From this, I think that it is perfectly clear that botanical systematists have certain imperative duties in regard to this subject. These duties are, in the first place, great caution in making changes, and, in the second place, a feeling of obligation, when these changes seem necessary, to state the reasons for them so clearly and forcibly that they will appeal to all thoughtful and discriminating workers in the same field. The burden of proof should always rest upon the writer suggesting the change.

What we need in botanical classification is a series of constants, a number of graded categories which can be generally endorsed and properly respected. Standards as definite as those of the physicist are, of course, quite unattainable in dealing with the variable and often intergrading groups of organic creation. But where absolute accuracy and uniformity are impossible, we should the more diligently seek to preserve such standards as exist. As has been pointed out, there are but few families of flowering plants which have not been comprehensively treated by monographers who, so far as their particular group was concerned, have been in a position to see pretty

1 From the address of Prof. B. L. Robinson, president of Section G, Botany.

clearly where it was best to draw generic lines. While it must be admitted that there are many minor differences in the generic concepts exhibited in the scholarly and monumental works to which I here refer, yet they establish a good usage, which on the whole has a considerable measure of uniformity, and goes far to establish the rank of such categories as genus, species, and variety.

Let me urge that, while we remit no effort to secure further light on this subject, there should be a general agreement to treat the accepted and traditional interpretation of large and important genera as sacred and binding until we can furnish definite and convincing evidence that change is needful, and that for the welfare and dignity of our science all should unite in opposing changes of the artificial sort, which consist merely in the shifting of ranks and modification of standards.

Investigations and Commercial Tests in Connection with the Work of an Engineering College.[1]

In any school it is necessary, in securing the best efficiency in instruction, that the professors shall be able to speak with authority on the subjects which they teach. In technical schools those who teach the practical engineering subjects cannot speak with authority unless they have had practical experience. Investigations and commercial tests may serve to give them this practical experience, and the question naturally arises, Is it a good policy for professors to conduct such work in connection with their regular college duties?

Let us consider the various ways in which a professor in an engineering school may acquire the practical experience which is necessary in his work.

First, he may be called to a professorship from the practical field.

Second, after teaching for a time and finding how necessary a practical experience is in his work, he may turn to the practical field, and then return to teaching.

Third, he may undertake practical work in connection with his college duties, and gain his experience in this way.

Each method possesses its own advantages and disadvantages. Starting with the first, it must be admitted that many of our best instructors have entered the teaching line after they have had experience in the practical field. Such a man has an advantage in being able to make use of this experience immediately, when he starts at his teaching work. There is a disadvantage, however, in the fact that should he have secured a mature experience in the practical field, he will necessarily be no longer a young man, and it may be hard for him to teach and properly to adapt himself to the theoretical part of his course.

The advantages of the second system of securing a practical experience, where the professor leaves the teaching field, takes up outside work, and then returns to teaching, are that during his practical career he will be very much alive to the points he should look into, and, furthermore, if he returns to teaching he will possess the advantage of having experience both as a teacher and as a practical engineer.

We will now take up the third method, where a professor obtains his practical experience by conducting outside work in connection with his college duties. The outside work undertaken by a professor should be that of a scientific or strictly engineering type.

The advantage to a college in having its professors do research and outside work is that what reflects to the credit of the professor will reflect to the credit of the college. Furthermore, the college will be looked to as a source from which an unbiased opinion can be obtained, and in maintaining this standard it will be fulfilling a high and useful mission. The results of the investigations may be made the subjects of scientific papers to be read before the various societies, and any reputation that a professor gains in this way will benefit his college.

The day is past when there can be a strict line drawn between the work of the consulting engineer and that of the professor who teaches in the same field. The ideal professor in a given line should be able to take up the work of the consulting engineer in that line, and the ideal consulting engineer should possess enough technical knowledge to fit him for being a professor. There should be no jealousy, but rather a bond of friendship in that the fundamentals which each should master are the same.

[1] From the address of Prof. D. S. Jacobus, president of Section D, Mechanical Science and Engineering.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The results of a census undertaken each year by the *Magazine* show that there are 2722 undergraduates actually in residence this term, as compared with 2021 in Hilary term, 1905. The increase is probably due to the Rhodes scholars and to the fact that a larger proportion of undergraduates now complete three years of residence than was the case a few years back. The three largest colleges are Christ Church, New College, and Balliol, with 211, 210, and 181 members in residence.

A long vacation course in geography will be held in Oxford between August 7 and 25, provided that sufficient names are sent to the Reader in Geography, Old Ashmolean Building, Oxford, by June 1. The course will include lectures and demonstrations in the School of Geography, and surveying and map-drawing in the field.

At a meeting of the Junior Scientific Club, held on Wednesday, February 14, at the museum, papers were read by Prof. Miers on "Spontaneous Crystallisation," and by Mr. C. G. E. Farmer on "The Use of Finely Divided Metals in Organic Chemistry."

CAMBRIDGE.—The regulations for the diploma in mining engineering were passed by the Senate last Thursday. Among the chief of these regulations is that the candidate may take such parts of the natural sciences tripos and of the special examination in mechanism and applied sciences as bear upon the subject of mining engineering, or a candidate may take honours in the mechanical sciences tripos. Details of the examination and the schedules in the art of mining and in metallurgy will be found in the *Cambridge University Reporter* for December 5, 1905.

The Smith's prizes for 1904 have been adjudged as follows, the names being in alphabetical order:—C. F. Russell, Pembroke, for his essay on "The Geometrical Interpretation of Apolar Binary Forms"; F. J. M. Stratton, Gonville and Caius College, for his essay on "A Problem in Tidal Evolution Suggested by the Motion of Saturn's Ninth Satellite."

Mr. J. W. Nicholson, of Trinity College, has been elected to the Isaac Newton studentship in astronomy and physical optics, of the value of 250*l.* for one year, for study and research in astronomy.

Mr. R. H. Rastall, late scholar of Christ's College, Harkness scholar in 1903, has been elected to a junior fellowship at Christ's College. Mr. Rastall has worked chiefly in the Geological Museum at Cambridge, and has written on the Blea Wyke beds of Yorkshire and on "The Buttermere and Ennerdale Granophyre" of Lakeland.

DR. C. H. LEES, lecturer in physics and assistant director of the physical laboratories of the University of Manchester, has been appointed professor of physics at the East London College.

THE King's Speech, read by His Majesty at the opening of Parliament on Monday, promised that, at the earliest possible moment, a Bill would be introduced "for amending the existing law with regard to education in England and Wales."

THE Lancashire County Education Committee has recommended the council to make a grant of 100*l.* a year to the fund for the establishment of a department in economic botany in the University of Liverpool. The cost of the proposed department has in consequence now been completely guaranteed.

THE Senate of the University of St. Andrews has resolved to confer the following honorary degrees, among others, at the graduation ceremonial on April 3:—LL.D., Dr. A. C. L. G. Gunther, F.R.S., in appreciation of his lifelong and distinguished labours in zoology, Prof. J. C. Wilson, Oxford, and Prof. A. H. Young, Manchester.

An open competitive examination for not fewer than twelve situations as assistant examiner in the Patent Office will be held by the Civil Service Commissioners in April next. The examination will commence on April 23, and forms of application for admission to it are now ready for issue, and may be obtained on request addressed by letter to the secretary, Civil Service Commission, Burlington Gardens, London, W.

At the annual conference of the Labour Representation Committee held on February 16 considerable discussion took place on the following resolution:—"That this conference condemns the educational policy of the Government as laid down in the Act of 1902, and demands the formulation of an educational programme based upon the principle of equal opportunities for all, such programme to aim at securing—(1) that immediate provision be made for giving at least one free meal per day to all school children; (2) that all grades of education shall be free and State maintained; (3) that all education shall be free, and that secondary and technological education be placed within the reach of every child by the granting of bursaries or maintenance scholarships to all children whose usefulness would be enhanced by such extended education; further, that adequate provision be made for children to continue at school until the age of sixteen years, or until such age as the university course begins; (4) that provision be made to continue the education of capable students through the university courses; (5) that the standard of capacity shall be judged by work previously accomplished, and not by competitive examination; (6) that the education in all State-supported schools shall be secular; (7) that all State-supported schools shall be under the control of and their affairs administered by the directly elected representatives of the people; (8) that each educational district shall be required to train the number of pupil teachers demanded by local needs, and for this purpose to establish training colleges, preferably in connection with universities or university colleges; (9) that the cost of the above-mentioned reforms shall be borne by the National Exchequer out of revenue obtained through broadening the basis of taxation, and by the restoration and democratic administration of valuable misappropriated educational charities and endowments." "This conference, therefore, instructs the committee (or such body as may be appointed for the purpose) to draft a Bill embodying the principle of the said resolution, with a view to the Labour group introducing it early into Parliament." A division having been taken, the result was declared as follows:—817,000 votes for the resolution and 76,000 for its rejection. The resolution was therefore carried. In view of the growing importance of the labour interest, it is satisfactory and gratifying to find a large and representative body of labour delegates appreciating the fact that the future welfare of the country is closely bound up with the provision of a rational system of national education.

The publication on February 19 of a correspondence between Mr. A. H. D. Acland, formerly Minister of Education, and Mr. Birrell, President of the Board of Education, is gratifying evidence that at last something is to be done in the direction of providing adequate Exchequer grants for English secondary education. Mr. Birrell, in reply to a series of suggestions made by Mr. Acland, announces that provision is to be made in the Estimates for this year for a considerable increase of the Exchequer grants (1) in aid of secondary schools; (2) to alleviate the burden now placed upon local authorities in respect of the education of teachers; and (3) to assist further the building of training colleges for teachers by the local authorities. How much higher education in this country has suffered from the inadequate education of boys in our secondary schools, which, through want of funds, are too often under- and inefficiently staffed and equipped, has been pointed out in these columns with patient persistence. It is earnestly to be hoped that the findings of the Royal Commission on Secondary Education of ten years ago will now be considered seriously, and a statesmanlike attempt made to secure for the pupils in whose hands our future success as a manufacturing nation lies, a rational and complete secondary education which will enable them to take proper advantage of higher technical instruction. The promise that local education authorities are to be helped—in a degree commensurate with modern needs—in the pressing work of supplying more training college accommodation is heartily to be welcomed. The proportion of fully trained teachers in our elementary schools is at present scandalously low; and this is due primarily to the fact that until quite recently the only training colleges were those built—with the aid of special State grants like that of 1835—by the National and the British and Foreign School Societies, and supported largely by Government grants on each teacher in training. Though in recent years the work of day training departments in connection with university colleges has improved the facilities for the training of teachers, much yet remains to be accomplished if English elementary education is to take advantage of modern educational enlightenment. Local education authorities, with their knowledge of local needs, will be in a position, when helped by the promised Treasury grants, to start the much needed provision of more colleges where teachers may become acquainted with the principles upon which successful teaching must be based. In carrying out this important work, the need of training for secondary school teachers must not be forgotten. Most masters in secondary schools begin their work knowing only what to teach, and nothing of how to teach.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 25.—"On the Effect of High Temperatures on Radium Emanation." By W. **Makower.** Communicated by Prof. Arthur Schuster, F.R.S.

(1) The activity of radium emanation in radio-active equilibrium with its products A, B, and C, is changed by heating above 1000° C.

(2) The effect increases with the temperature up to 1200° C., and possibly beyond this temperature.

(3) The effect increases with the time of heating for about the first hour, but subsequent heating is without effect.

PARIS.

Academy of Sciences, February 12.—M. H. Poincaré in the chair.—Some properties of the α rays emitted by radium and by bodies rendered active by radium: Henri **Becquerel.** Some experiments of Prof. Rutherford recently published have led the author to repeat some of his earlier work on the deviation of the radium rays. In the present paper full details are given of the strength of the magnetic field, and the dimensions and arrangement of the apparatus. As a result, M. Becquerel definitely rejects the interpretation deduced by him from his earlier experiments and the hypothesis of an increase in the radius of curvature along the trajectory, and accepts the explanation of Prof. Rutherford, all the measurements confirming the existence of a reduced velocity for the α rays when traversing a leaf of aluminium. There is no difference in the behaviour of α rays arising from radium salts or from bodies rendered active by the emanation.—The internal pressure of fluids and the equation of Clausius: E. H. **Amagat.**—Some lemmas relating to quasi-waves of shock: P. **Duhem.**—Observation of the eclipse of the moon of February 9, 1906, made at the Observatory of Paris: P. **Salet.** Note on the time of contact, with especial reference to the difference observed between the photographic and visual observations in different eclipses.—Observations of the Brooks comet (1906*a*) made at the Observatory of Algiers with the 31·8 cm. equatorial: MM. **Rambaud** and **Sy.** Observations on the apparent positions of the comet and the positions of the comparison stars were made on January 31 and February 2. On January 31 the comet had the appearance of a round nebulosity with an eccentric nucleus, with a lustre comparable with that of a star of the eleventh magnitude.—Observations of the sun made at the Observatory of Lyons with the 16 cm. Brunner equatorial during the third quarter of 1905: J. **Guillaume.** Fifty-six days were available for observations during the quarter, the results of which are summarised in three tables showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—Integral functions: Ed. **Maillet.**—A

hyperelliptic Hessian. Louis **Remy.**—The extinction of a solitary wave propagated along a horizontal elastic tube: A. **Boulanger.**—A comparison of the time of discharge in an X-ray tube and of a spark in series with the tube producing the rays: Bernard **Brunhes.** Remarks on a recent paper by M. André Broca, and directing attention to a paper published by the author in 1900 on the same subject.—The recombination of the ions in saline vapours: G. **Moreau.** The ions of salt vapours, both by their mobilities and by the values of the coefficient α, for temperatures between 170° C. and 0° C., are intermediate between the ions of ordinary gases and the large ions due to the oxidation of phosphorus. Their mass diminishes as the temperature rises, and in a flame, for the negative ion, they become comparable with kathodic particles, and, for the positive ion, with the atom of hydrogen.—Remarks on the combinations of the rare metals of the cerium group and on their sulphates: Camille **Matignon.** A reply to a claim for priority made by M. Otto Brill.—Calcium iodomercurates: A. **Duboin.** These salts are prepared by alternately adding calcium iodide and mercuric iodide to water, finishing with a slight excess of the calcium salt. The solution had a density of 2·89 at 16° C., and three crystalline compounds were isolated from the solution.—The existence of sulphides of phosphorus: H. **Giran.** Various mixtures of phosphorus and sulphur were heated in sealed tubes to 200° C., and the melting points taken after solidification. The results are given graphically. The four maximum points correspond exactly to the proportions of sulphur indicated by the sulphides P_4S_3, P_2S_3, P_2S_5, and PS_6.—The preparation and properties of strontium: MM. **Guntz** and **Rœderer.** Strontium amalgam is heated in a current of hydrogen until the whole of the mercury is expelled, strontium hydride remaining. This hydride, heated in a vacuum at 1000° C., is dissociated, the vapours of strontium being condensed on a cool tube. The metal thus produced contained 99·43 per cent. of strontium, and was utilised in redetermining some thermochemical data.—The action of some esters of some dibasic acids on the halogen-magnesium derivatives of the primary aromatic amines: F. **Bodroux.**—The constitution of the sulphates of chromium: Albert **Colson.**—The existence of bicarbonates in mineral waters, and on the supposed anomalies of their osmotic pressure: L. C. **Maillard** and Lucien **Graux.** For one specimen of mineral water it is shown that the cryoscopic results are not opposed to the idea of the existence of bicarbonates in mineral water.—A new mode of extraction of oil of anise: Ph. **Eberhardt.** The oil can be extracted from the leaves as well as the fruit.—The anti-coagulating power of the blood serum of the lower animals: J. **Sellier.** Serum extracted from some fishes and invertebrates has the power of preventing the coagulation of milk by rennet.—The annelids of the Red Sea: Ch. **Gravier.**—The salivary glands of the snail (*Helix pomata*): M. **Pacaut** and P. **Vigier.**—The mechanism of the pathological modality special to each organ in the course of a general disease: A. **Charrin.**

MATHEMATICAL ASTRONOMY.

The Collected Mathematical Works of George William Hill. Vol. i. Pp. xviii+363. (Washington: The Carnegie Institution, 1905.)

IT is a rare mind that can handle the cumbrous developments of practical astronomy and leave uppermost with a reader the impression of variety, ease, and polish; and curiosity will be felt as to the circumstances which have developed Hill's remarkable powers. From an interesting introduction to the present volume by M. Poincaré we learn that he spent three years at Rutgers College, New Jersey, under a certain Dr. Strong. Dr. Strong "était un homme de tradition, un laudator temporis acti; pour lui Euler était le Dieu des Mathématiques, et après lui la décadence avait commencé; il est vrai que c'est là un dieu que l'on peut adorer avec profit," and if it led Hill to the study of originals, we may overlook the depreciation of the moderns. From New Jersey he went to Cambridge to continue his studies at Harvard; very soon here, by a paper contributed for a prize to a mathematical miscellany, he attracted the notice of Runkle, the editor, who was Newcomb's predecessor at the office of the *American Ephemeris*. Hill became attached to the *Ephemeris* as computer, and remained in discharge of these duties for thirty-two years. At first he worked at his own home, as was then the custom; but under Newcomb's management, and in order to complete his theory and tables of Jupiter and Saturn he lived for some years at Washington, incessantly absorbed in his task. "The only defect of his make-up of which I have reason to complain," Newcomb has written, "is the lack of the teaching faculty." In 1892 he withdrew to the little farm where his boyhood was passed, and where he still lives, asking nothing but the liberty to continue his labours.

The present volume carries us up to 1881, and includes most, but by no means all, of his best known papers. The essay which attracted Runkle's notice is No. 3, "On the Conformation of the Earth," and was written at the age of twenty-three. It is perhaps not of any permanent importance, yet it is marked by the clearness and the firm hand of his later writings and the same salutary determination that theory should give an account of itself arithmetically. It is natural to compare it with Stokes's memoir "On the Variation of Gravity," written some twelve years before, when he also was a young man, and the comparison shows strikingly how Stokes is the physicist and Hill the analyst.

The two great memoirs by which Hill is best known are No. 29, "On the Part of the Motion of the Lunar Perigee which is a Function of the Mean Motions of the Sun and Moon," and No. 32, "Researches in the Lunar Theory." These writings have been greatly praised, but it seems impossible to praise them too highly, whether for their difficulties or the way these are overcome, or the greatness of the advance which their solution implies. The latter paper was the first which threw any real light upon the general problem of three bodies, and it is well worth notice how large a part arithmetic plays in its success. The analysis is pregnant in the extreme, but it is the actual calculation of a whole sequence of periodic orbits which a moon might occupy that gives it shape and name.

If this memoir may be said to be the first significant word on the problem of three bodies, the former one, on the motion of the lunar perigee, seems to be almost the last word on a question that had outrun calculation from Newton's day to Delaunay's. It is doubtful whether the more determined effort to calculate this quantity was made by Newton or by Delaunay, but though naturally the degrees of approximation they attained were very different, they had this in common, that they proved the inadequacy of the methods employed. Hill first, with the smoothness of a conjurer, gives form to the intractable equations, and then shows how the solution is contained in a certain transcendental equation, an infinite determinant. It affords striking evidence of Hill's power to contrast his treatment of this determinant with that of Adams, who followed a similar route, *sed longo intervallo*, as he said himself. The complexity arising from an infinite sequence of equations might seem to preclude any general conclusions from being drawn, but Hill uses this very feature in the most beautiful manner to derive the eliminant in a transcendental form in the shape $\cos \pi c =$ a known quantity, and from this equation determines c, the required ratio. The secret of the success is now apparent. c is nearly equal to unity; hence it is very much easier to approximate to $\cos \pi c$, where we are in the neighbourhood of a stationary value, than to c directly; and though the difficulty recurs when we seek to find the arc πc from a cosine in the neighbourhood of its minimum, it is then an insignificant one, for we are past the true complexities of the problem.[1]

The remaining papers are naturally not of equal moment with these, but we may be grateful to the Carnegie Institution for making them accessible in the present collection. Several of them arose in connection with Hill's duties as computer to the *Ephemeris*, but even on such hackneyed subjects as eclipse computing and reduction of star places he has something good to say. He is a true artist; *nullum quod tetigit non ornavit*. Of considerable general interest are No. 18, "Remarks on the Stability of Planetary Systems," and No. 14, "A Method of Computing Absolute Perturbations," which contains a rescension of Hansen. Even the smaller papers, like No. 22, "On the Solution of the Cubic and Biquadratic Equations," are usually marked by some analytical felicity that makes one wish that Hill had been able to bring his great powers to bear upon a material not so invariably intractable and overloaded with tradition, and limited in its problems, as practical astronomy. But if we feel that his hand

[1] The point of this approximation is put somewhat incorrectly by M. Poincaré in his introduction.

is subdued to what it works in, we feel, too, that that is an essential ingredient of his success, and that with less complete absorption his work might have been less brilliant as well as less convincing.

R. A. S.

ULTRAMICROSCOPIC STUDIES OF THE COLLOIDS.

Zur Erkenntniss der Kolloide. Ueber irreversible Hydrosole und Ultramikroskopie. By Richard Zsigmondy. Pp. vi+185. (Jena: Gustav Fischer, 1905.) Price 4 marks.

THIS work forms a valuable addition to the literature of the colloids, giving as it does an authoritative account of the results obtained through the application of the method of ultramicroscopy to the study of solutions of colloids.

A brief account is first given of the nature and properties of colloid solutions or hydrosols. At the outset the author refers to the difficulty of giving a satisfactory definition of the term "solution." He adopts homogeneity as the most universal characteristic of solutions. The definition of homogeneity will naturally vary according to the delicacy of the methods employed to test it. By means of the method of ultramicroscopy devised by Zsigmondy and Siedentopf, the majority of colloid and even some crystalloid solutions can be shown to be optically heterogeneous. Every increase in the accuracy of the methods of examination would lead to a further limitation of the term "solution." In order to include the colloids Zsigmondy defines solutions as uniform distributions of solids in fluids, which are transparent to ordinary light, and not separable into their constituents by the action of gravity or by filtration.

In order to gain a clearer idea of the nature of colloid solutions, it is necessary to find criteria for distinguishing such solutions from those of crystalloids on the one hand and from suspensions on the other. Zsigmondy only refers very briefly to the distinguishing characteristics of the former, as this subject has been previously treated by Bredig in his monograph on "Inorganic Ferments." He deals more fully with the properties of colloid solutions which distinguish them from suspensions. In this connection he mentions the following as the chief features distinguishing colloid solutions from suspensions:—

(1) The particles in colloid solutions are much smaller than in suspensions. In colloid solutions the average diameter of the particles varies from 5 to 20 $\mu\mu$. This difference is, however, one only of degree.

(2) Many colloids are capable of undergoing irreversible changes. Separation of a metal from its colloid solution may be readily brought about by the withdrawal of water or the addition of electrolytes. In this process the metal has undergone an irreversible alteration or coagulation. For the reformation of the colloid solution, chemical or electrical means must be employed. In the case of suspensions, on the other hand, sedimentation rapidly takes place under the influence of gravity, and its rate is little influenced by the withdrawal of water or by the addition of electrolytes. The suspension may be reformed by purely mechanical means.

(3) Alterations in the total energy of the system are frequently associated with the process of coagulation. These have been measured in several cases by means of the calorimeter.

(4) Colloids in solutions are capable of undergoing reactions with one another, which closely simulate purely chemical reactions.

The next section of the book deals with the classification of colloid solutions or hydrosols. The classifications of the hydrosols have been based on two principles, namely, the size of the particles and the reversibility or irreversibility of the hydrosol (Hardy). On plate i. the author gives a graphic representation of a classification of colloids founded on these principles. The reversible colloids differ from the irreversible in not being readily coagulated by the addition of electrolytes. It is noteworthy that irreversible colloids may be partially protected from the coagulating action of electrolytes by the addition of a reversible colloid to their solutions. Great quantitative differences are found to exist in the extent of protection given by different reversible organic colloids to irreversible gold hydrosols.

A historical account of the preparation and properties of irreversible colloid solutions occupies the next section of the book.

The author next gives an interesting account of the development of the method of ultramicroscopy by Siedentopf and himself. A full description is also given of the necessary apparatus and of the method of using it.

The succeeding sections give details of the results of his own researches on gold hydrosols. By means of the ultramicroscope he was enabled to determine approximately the average size of the gold particles, their colour, and the rapidity of their movements both translatory and oscillatory. The limit of size determinable by the ultramicroscope appears to be about 6 $\mu\mu$ in the case of gold hydrosols. Still smaller particles (amicrones) are also present in gold hydrosols. Their presence may be proved by the coagulation of the hydrosols on the addition of electrolytes.

An excellent summary is also given of the results obtained by other observers through examination of various colloid solutions by means of the ultramicroscope.

Brief reference only is made to some points of great theoretical interest, namely, the causes of the stability of colloid solutions, and the mechanism of their formation.

The book concludes with a short summary of what is known with regard to the products of coagulation of colloid solutions.

The work as a whole is to be regarded as a valuable monograph indispensable for those interested in the ultramicroscope and its applications.

J. A. MILROY.

SCIENCE IN ARCHÆOLOGY.

Manuel de Recherches préhistoriques. Issued by the Société préhistorique de France. Pp. 332; with 205 figures and 4 plates. (Paris: Schleicher Frères, éditeurs, 1906.) Price 8 francs.

Last year an eminent English Egyptologist published a handbook for excavators, with especial reference to Egypt, and remarked in his preface that "a complete archæological training would require a full knowledge of history and art, a fair use of languages, and a working familiarity with many sciences." The present work embraces a large number of subjects that should be familiar to the practical archæologist, especially if engaged in field-work on French soil.

The manual is issued by the Prehistoric Society of France, and has been written by several of its leading members. Taken in conjunction with the first congress of the society, held in the autumn at Périgueux, it indicates a widespread interest in the remote past as represented by flint implements, cave deposits, dolmens, and Gaulish burials. Of recent years, more and more emphasis has been laid on the need for systematic excavation as opposed to haphazard relic-hunting by amateurs; and this publication is intended, not only to assist the explorer in his search for records of the past, but also to render them accessible and self-explanatory when found. Private interest and personal feeling always stand in the way of corporate action in such investigations, but much would be gained if the advice contained in this manual were followed by the depredator, if only for his own ends. To put it on the lowest ground, relics accurately labelled and located gain enormously, not only in scientific, but also in market value; and if archæology is to justify its claim to be regarded as a science, scientific exploration must be the rule, and not the rare exception.

The chapters are all much compressed, and none can be singled out as more important than another. There are instructions for all the ordinary branches of exploration in a most compact form; but in spite of the French tradition, we venture to think that the volume would have been even more practical if published in a light but stout binding. A handbook in a paper wrapper is hardly fit for use in the field. Attention may be directed to the method of hardening and preserving skeletons and other bones by means of silicate of potash, and to the practical advantages of the process advocated for preserving iron. This metal is the scourge of museum curators, and neither the soda nor paraffin treatment has proved altogether successful. The simpler, and apparently the more satisfactory, method is to allow the metal to dry for several hours after brushing in water, and then to heat it to a dull red; if allowed to cool slowly, the object should then be rust-proof, and the surface clean and firm.

One of the most useful features of the manual is the table for computing the height of a subject from various bones of the skeleton; this method would no doubt greatly reduce the number of 7-feet skeletons found even in this country. Another point on which emphasis is laid is the desirability of photographing dolmens, menhirs, and other antiquities of the kind precisely from the four cardinal points; picturesque views are dear to the ordinary photographer, but are of little value for purposes of comparison. On this point a caution should have been given as to the difference between the true and magnetic north, as accurate compass bearings of megalithic monuments may often prove of considerable importance.

The student of prehistoric archæology in France and elsewhere will be glad to find the various classifications of the Stone age brought together, even if no attempt is made to coordinate them. The most important are those of Mortillet, Piette, Salmon, Boule, and Rutot, and in the last mentioned occurs (as occasionally elsewhere) the irritating term "Forest Cromer bed." Among the few cases where no scale is indicated for the illustrations is that of the Pressigny nucleus (Fig. 74); the extraordinary size of these flints ought surely to have been stated. Finally, it is somewhat of a shock to the orthodox to find the following item in the glossary at the end:—"*Bulbe de percussion.*—Mot impropre (voir *Conchoïde*)."

OUR BOOK SHELF.

Smoke Abatement: a Manual for the Use of Manufacturers, Inspectors, Medical Officers of Health, Engineers, and Others. By William Nicholson. Pp. xiii+256. (London: Charles Griffin and Co., Ltd.) Price 6s. net.

The author of this handbook is chief inspector to the Sheffield Corporation, and seems to have an extensive acquaintance with the various enactments that have been passed in this and other countries with a view to ameliorate one of the greatest nuisances of modern times, and devotes more than a third of the 250 pages the book contains to their recital. This is undoubtedly useful to those desiring to make themselves acquainted with the legal aspects of the case, but scarcely justifies the subtitle of a "practical handbook," as the author's idea of the nature of smoke is of a most delightfully rudimentary character, and his power, therefore, of prescribing remedies necessarily limited. On searching the book for a clear definition of smoke and a description of the constituents that go to build it up, we find on p. 12 the following:—"Nature of the Nuisance—Smoke consists of minute particles of carbon together with a sticky tarry matter which settles and sticks to everything it comes in contact with. It is dirt. Lord Palmerston's definition of dirt from a health point of view is 'Matter in the wrong place,' and carbon or coal in the atmosphere is matter in the wrong place."

One of the chief remedies suggested by Mr. Nicholson is that the Sanitary Institute should now deal with the question, and arrange for courses of lectures on the subjects of "Smoke and the Injury therefrom," "The Causes of Smoke," and "The Practical Prevention of Smoke," after which examinations should be held, and "certificates of competency given to all who satisfy the examiners." The result of this is foreshadowed by the author as follows:—

"If such facilities were offered, hundreds of engineers and others would avail themselves of them, and would not rest satisfied until they had procured a smoke inspector's certificate, which would become as popular and as valuable as the sanitary inspector's

certificate. Having obtained the certificate and possessing the theoretical as well as the practical knowledge, they would quickly be on the look-out for official appointments, and if there was an unwillingness on the part of the Local Authorities to appoint them, the necessary pressure to compel them to do so would be forthcoming."

If Mr. Nicholson could induce the Sanitary Institute to add a lecture on "The Nature of Smoke" to the course he prescribes, and was to attend it, he would find the information of distinct advantage in dealing with "smoke abatement."

The Preservation of Antiquities, a Handbook for Curators. Translated from the German of Dr. Friedrich Rathgen by Dr. G. A. Auden and Dr. H. A. Auden. Pp. xiv+176; with 48 figures in the text. (Cambridge: University Press, 1905.) Price 4*s.* 6*d.* net.

DR. RATHGEN states in his preface to the German edition of this little book that it is intended to stimulate curators and others interested in the preservation of antiquities to make public their experiences in this branch of archæology.

The first part deals with the changes brought about by the long-continued action of soil, moisture, and air on metals, glass, organic substances, limestone and clay; the materials of which "antiquities" are most usually composed. This is a subject about which very little is known, one of the commonest cases, the "rusting of iron," being still a subject for argument and speculation among chemists. The author, therefore, is only able, as a rule, to state the effects produced by these natural agents, and in comparatively few cases can suggestions be made as to the modes by which these effects are brought about.

In the second part, methods of cleansing recently disinterred antiquities of various kinds and of preserving them are given, and here the author is able to quote largely and usefully from his own wide experience of this work.

The translators have added to the English edition some notes of recent work and additional illustrations which are useful in elucidating various points in the text. The book should be useful not only to curators for reference, but should prove suggestive to all interested in the preservation of natural or artificial structures exposed to the action of air, soil, or moisture.

Organography of Plants. By Dr. K. Goebel. Authorised English edition by Prof. I. Bayley Balfour. Part i., pp. xvi+270. 10*s.* net. Part ii., pp. xiv+708. 21*s.* net. (Oxford: The Clarendon Press.)

THE German edition of the "Organography" has already been reviewed in NATURE (vols. lviii., p. 74, lxiii., p. 149, lxvi., p. 51), and it is unnecessary, therefore, to insist again on the importance of Prof. Goebel's book, both to botanists and to others who are interested in the development of plant life.

The Clarendon Press is to be congratulated on having secured Prof. Bayley Balfour to undertake the responsibility of preparing the English edition, and his name on the title-page carries with it the assurance that the work has been well done. Moreover, his great knowledge of plants has enabled him to give that indefinable cast of originality and interest to the translation that one so often misses in presentations of this kind.

The text is well broken up, by means of headlines and by the use of different founts of type, thus rendering the book more easy to use. The printing, and also the figures, are excellent, and there is a good index, both of illustrations and of subject-matter.

Both the Clarendon Press and the editor have laid English-speaking botanists under obligation by the excellent production in our own language of this important work. J. B. F.

Catalogue of the Madreporarian Corals in the British Museum (Natural History). Vol. v., The Family Poritidæ, ii., The Genus Porites, Part i., Porites of the Indo-Pacific Region. By Henry M. Bernard. Pp. vi+303+xxxv plates. (London: The Trustees of the British Museum, 1905.)

IN the preparation of this important catalogue Mr. Bernard was confronted with the difficulty, experienced by nearly all naturalists who have attempted to arrange corals in specific groups, that the characters afforded by the skeletal structures only are so variable that there is no possibility of accurately defining the limits of "species." This is a difficulty which is wont to grow rather than dwindle as our knowledge of specimens of a genus increases, and Porites being a common and widely distributed coral, represented in the museum by very many specimens from numerous localities, the difficulty presented itself in a particularly exaggerated form.

No one will deny that the binomial system when applied to such a genus is unsatisfactory, and it will probably remain so unless further investigation of the anatomy of the living polyps reveals some characters of better value for purposes of classification. But the system adopted by Mr. Bernard, of abandoning the old specific names and giving the specimens a geographical label and a number, does not appear to offer a more satisfactory solution of the problem, and will not, probably, be generally approved. Unsatisfactory as they may be, many of these specific names are of some value, and all of them of historical interest. To sweep them all away at a stroke is a drastic measure which cannot be recommended, either on the ground of science or expediency.

But even if Mr. Bernard's system is disapproved, naturalists will undoubtedly agree in their tribute of thanks for the skill and patience he has displayed in building up this monumental work on the Indo-Polynesian specimens of the genus. The detailed description of the specimens in the museum will be of value to those who may, in the future, be tempted to grapple with the species question in the genus; but a real and important contribution to knowledge is to be found in the concise statements concerning the morphology of the skeleton and the affinities of the genus. The catalogue is adequately illustrated.

Microscopes and Accessories: How to Make and Use Them. Edited by Paul N. Hasluck. Pp. 160. (London: Cassell and Co., Ltd., 1905.) Price 1*s.* net.

WE are very doubtful whether the first portion of this book, dealing with the practical construction of a microscope by the amateur, will serve any useful purpose. Such an instrument, however well constructed, must almost inevitably fall far short of the perfection attained by the instrument makers, even if the amateur be a first-class mechanic, and efficient instruments may nowadays be picked up second-hand at ridiculously low prices. In the description of the tube, all that is said with regard to the attachment of the objective is that at the bottom (of the tube) a disc of brass is sweated on, the hole in its centre being $\frac{7}{8}$ in. diameter, and chased with a fine thread; not a word about the standard screw now adopted by all makers. The latter portion of the book, dealing with the preparation and mounting of objects, is concise and to the point, but presents nothing novel in its treatment of the subject. R. T. HEWLETT.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Cooperation between Scientific Libraries.

THE note in NATURE (February 15, p. 372) on Dr. T. Muir's paper in the Proceedings of the Royal Society of Edinburgh directs attention to a difficulty which, as you rightly say, affects many others than the mathematicians of Scotland. You adduce, for example, Wales; but may I, without giving offence to the Principality, venture to suggest that the metropolis itself has still better claims to dishonourable mention?

In the two sciences which chiefly appeal to me, geology and zoology, the difficulty mentioned by Dr. Muir has long presented itself forcibly, and there is a lengthy list of books that I have been trying to see in vain, some of them for more than five years. They are, so far as I can ascertain, in none of the many libraries of this city. Naturally, the remedy suggested by Dr. Muir long ago presented itself to me, and I have lost no opportunity of urging it in conversation and in print. In view of your own recognition of the importance of the subject, I venture to ask you to reprint for a wider public the following paragraph from a paper contributed to the *Museums Journal* for April, 1902. After alluding to the cooperation between American libraries in the matter of cataloguing, and to the specialisation among the libraries of Chicago, I wrote:—

"The extraordinary difficulty that a student has, even in London, in seeing the literature of his subject—in fact, the impossibility, unless he is prepared to spend large sums of money on his private library—must have made many a one long for the day when the learned societies and other library authorities of London shall take this question of cooperation in hand. To what end is all this fuss about an international catalogue of scientific literature, with its elaborate mechanism and enormous expense, if, when the list of books is in his hands, it be still impossible for the student to refer to them? The amount of money annually spent by Government, through the libraries of the British Museum, the Education Department, the Patent Office, and the like, when joined with that spent by the great societies, such as the Royal, the Zoological, the Linnean, the Geographical, the Geological, with the College of Surgeons and other public bodies of like character, is surely enough, if properly administered, to buy the world's output of books each year; and far more than enough, if we remember that all publications of the United Kingdom go to the British Museum as a matter of course, and that the donation lists of many of these libraries are nearly as big as their purchase lists. If only the money could be pooled, and the purchases distributed according to some pre-arranged scheme among the various libraries; and if a joint catalogue were prepared, and kept up from month to month, showing not only the titles of books, periodicals, and papers, but the libraries in which they were to be found, then weary searching and fruitless wandering would no longer be the lot of the conscientious student. Even as things are, without so radical a reform as a redistribution of income, I feel sure that a conference of librarians, bent rather on furthering the interests of the reader than the pride of their own institutions, and armed with the necessary powers for cooperation, would soon lift London libraries out of the hopeless muddle that we now have to struggle with."

I hope that now this subject has been taken up in your influential pages it will not be allowed to drop until those concerned have at least attempted the remedy.

F. A. BATHER.

The Blondlot *n*-Rays

IT would be interesting to know whether anyone has obtained success in repeating the latest experiment designed to show the objective reality of the *n*-rays, viz. that described by M. C. Gutton in *Comptes rendus* for January 15.

The writer has repeated M. Gutton's experiment with much care, but has met with no more success in obtaining any positive result than he has in repeating a large number of M. Blondlot's own experiments, most of which he has essayed, in all cases with absolutely negative results, provided proper precautions were taken to avoid effects due to temperature and other extraneous causes of disturbance.

According to M. Gutton's experiment, the effect of the *n*-rays that proceed from a Nernst electric lamp upon a spark in a primary circuit is to diminish the brilliancy of another spark electrically induced in a secondary circuit by the primary discharge. Here one would suppose that the degree of brilliancy of the secondary spark can only be a matter of the amount of the electrical energy in the secondary circuit, but the writer finds that a very sensitive Duddell thermo-galvanometer, which would indicate a very small percentage of variation in the amount of this energy, shows no variation whatever.

66 Victoria Street, London, S.W., February 20.

A 300-Year Climatic and Solar Cycle.

IN June, 1902, I made a few remarks on an apparent coincidence between sun-spot periods and longer periods of rainfall and famine in north China. Not being, in any sense, a meteorologist, I did not publish my conclusions except locally. In connection with a notice in the "Astronomical Column" of NATURE, November 9 last (vol. lxxiii. p. 38), they are of sufficient general importance to recall them. The notice in NATURE is headed "A 300-year Cycle in Solar Phenomena," and refers to a discussion in the *Astrophysical Journal* wherein Mr. H. W. Clough, of the Washington Weather Bureau, arrives at the conclusion that a 300-year cycle exists in solar and the allied terrestrial phenomena, and finds likewise an intermediate 36-year cycle, and supports both by a reference to various phenomena, such as auroræ, periods of grape harvest, &c.

In 1877 Mr. A. Hosie, H.M. Consul at Chengtu, published a paper in the Journal of the China Branch of the Royal Asiatic Society on droughts in China (new series, xii., 51), extracted from Chinese records. As the records included all China, south as well as north, the tables did not at first sight exhibit any apparent periodicity. Some years after, on making a careful division into north and south, I was struck with a remarkable period of about 300 years, which seemed to me marked clearly in north China as an especial era of drought and famine. As, however, there seemed no reason for founding a new period, for the intercalation of which there was as yet no accumulated evidence, I proceeded no further with the subject. Mr. Hosie's paper went from the year 620 to 1643, covering a period of 1023 years, and attached to it was another notice of sun-spots observed in China, also going back for some 1300 years. The latter table, on account of the want of any observation instruments, is, of course, very fragmentary, but at the time I deduced from it without reference to European observations, which I had not by me, a probable period of 99 maxima in the 1920 years covered, which seemingly gave a mean of 11·085 years, and which, produced to modern times, fell in sufficiently satisfactorily with the European records of the last century. Sir Norman Lockyer in 1901 had also published observations bearing on a climatic curve of about six sun-spot periods, and commenting on all these I made the following remarks, which are entirely confirmative of Mr. Clough's findings, although deduced from such entirely different authorities.

"I now come to the long period or era which Mr. Hosie's records seem to require. The first of these calling for notice seems to cover the three sun-spot periods 664–697, though this is not so well marked as the others. The second covers the similar period from the maximum in 963 to that in 996, when besides two years of drought in northern China, 961 and 962, we find no less than twenty-three years out of the thirty-three characterised by excessive droughts in one or more of the northern provinces. The third covers the periods 1262–1295, when, in addition to the antecedent year 1260, there are noted twenty-one years of drought in the same provinces. The fourth is included between the spot maxima of 1561 and 1594, and though not so marked as the second and third, yet ten years of

drought are recorded, besides the preliminary drought years of 1557–1558. The fifth will, then, cover the equally well marked cycle of drought, which, beginning in or about the year 1860, has continued with scarcely an exception up to the present."

This was written in 1902, and it is noticeable that, as required by the cycle, the intervening years have proved of normal rainfall in northern China. Proceeding, I stated:—

"We have thus four well marked eras of 299·25 years, the beginnings of which in each case were marked by perfectly similar climatal phenomena, each being characterised as a period of drought in some special locality. It has always seemed to me that meteorologists have been in the habit of excessive generalisation, and that the true way to arrive at the secular variations of climate is to compare all observations made within a limited locality, where the conditions are more or less specialised. The mean rainfall of China, as I remarked at the beginning, would not have afforded the necessary data for such a comparison as I have attempted, the reason being that droughts in north and south China are in effect complementary, and never occur contemporaneously: and herein lies the key to the phenomena.

"According to the accepted theory of the 'monsoon,' it is produced by the excessive heating of the continent of Asia between the degrees of 35 and 45 N.L. which causes the rarefied air to flow off and leaves a partial vacuum to be filled in by moist warm air rushing across the equator. If from any cause the heat radiated from the sun be greater one year than another, the regions where the monsoons are elaborated are raised to a higher temperature, and the force of the monsoon increased, and the warm air carrying an extra supply of moisture is carried further north and spread over a wider area; hence the north of China, the usual limit of the monsoon, is superabundantly watered.

"If, however, the heating of the surface be insufficient to set up the normal circulation, the moisture from the tropics is dumped down in or about the latitude of the Yangtse basin, and mid-China receives a superabundant supply of rain, while the entire north is parched, and famine in one or more province is the result. Hence a wet summer in Shanghai is rarely or never accompanied by a sufficient rainfall in the north."

Similar conditions to a large extent prevail in India, and hence it has happened that the latter third of the last century was a period of drought and famine, which severely taxed the resources of the country. I wound up the note with the following remarks:—"It is not for me to suggest an explanation. But the 299¼ year will probably be found to depend on some hitherto unsuspected cosmical cause."

I do not pretend in this to take any credit to myself for any discovery. My part was confined to drawing up a column of centuries divided into three lines; in one was marked the year, in the second the dates when sun-spots had been observed, and in the third the years when droughts had been recorded in the northern provinces; in each of the latter a dark line was drawn across the column. The result was remarkable at the first glance, the dark lines congregating themselves thickly at the ends of the seventh, tenth, thirteenth, and sixteenth centuries, the rest being almost a blank. Personal experience showed me how the nineteenth century had followed the same rule. Mr. Clough's observations may therefore be looked upon as fully borne out by Chinese records; and it only remains to ascertain the cause of the phenomenon, which has certainly had a very considerable effect on the history of Asia.

I may point out the curious coincidence that the climatic cycle of about thirty-four years seems to agree with three sun-spot cycles, while the greater period of 299¼ would seem to correspond with twenty-seven.

Shanghai, January 8. THOS. W. KINGSMILL.

The Origin of Bronze.

IN connection with Prof. W. Gowland's remarks on the origin of bronze in his presidential address to the Anthropological Institute, abstracted in your issue of February 15 (p. 381), it may be of interest to direct attention to the fact that Plutarch, in his "De defectu oraculorum," refers to worked-out copper deposits in the island of Eubœa, from which were formerly manufactured swords which were "cold-forged" (ψυχρήλατος), and in this connection he quotes Æschylus, who mentions a "self-sharpened (αὐτόθηκτος) Eubœan sword," self-sharpened meaning, I presume, sharpened without fire. I believe that bronze containing only a small proportion of tin is malleable in the cold, but do not know if this would be the case with that referred to by Prof. Gowland as containing antimony. It would be interesting to know if tin is associated with copper in Eubœa. Swords of pure copper would hardly be of much use.

JOHN W. EVANS.

Imperial Institute, February 23.

Result of War affected by Soldier's Stature.

MR. TWIGG at p. 340 of your issue of February 8 points out that the Japanese had an unquestionable advantage in the recent war, as being smaller than the Russians—they were smaller targets for fire-arms. This is quite correct, but the advantage is inversely as the cubes of their heights, and not as the squares only, which would only apply to plank dummies. Bullets come from all sides, and not from the front only, so that the thickness of the men's bodies must be taken into account as well as their height and breadth. The average targets offered by each to the enemy are (taking Mr. Twigg's figures) as the cubes of 1585 and 1642, or as 106 to 118, an advantage in favour of the Japanese of about 12 per cent., or nearly double that calculated by Mr. Twigg.

W. E. WARRAND.

Westhorpe Hall, Notts, February 24.

TWO BOOKS ON BIRDS.[1]

TO watch the ways and habits of birds is a taste which is growing rapidly. Some watchers of birds, indeed, are not content to stop at observing their habits; they want to know how the birds acquired those habits and of what use they are to them. They speculate upon what a certain habit, if persisted in, may ultimately lead to. They wish to know, among other things, how a bird came by its colours, and what purpose in the bird's economy is served by, for instance, the red inside to its mouth, seen only when it gapes. And when careful, minute, and scrupulously accurate observers write down on the spot what they see, or think they see, natural history will always be the richer for their labours; and the theories and speculations which these inquisitors weave from what they have seen and heard cannot fail to prove interesting and suggestive reading.

Mr. Selous, at once the pioneer and the great exponent of this "close observation," who in a former work on bird watching touched upon the birds of the Shetlands, returned to his loved islands two years later, and now gives us a whole volume devoted to their birds and seals. In some three dozen short chapters he discourses, with digressions, delightfully upon his experiences. With the exception of a few "peckings," and minor interpolations—mostly having to do with the working out of ideas jotted down in the rough—the chapters contain his journal, written from day to day amidst the birds with whom he lived without another companion on one or other of these remote islands, "hated by thousands" of birds, and feeling himself the most unpopular person on the island. Nothing more need be said to recommend the book to the notice of those who follow birds in the field. For his digressions, leading him sometimes wide of the subject of birds, the author does not apologise.

[1] "The Bird Watcher in the Shetlands. With some Notes on Seals—and Digressions." By Edmund Selous. Pp. xii+338; with 10 illustrations by J. Smit. (London: J. M. Dent and Co., 1905.) Price 10s 6d. net.

"Nature-Tones and Undertones." Being Sketches of Life in the Open. Illustrated by Photographs from Nature. By J. Maclair Boraston. Pp. 223. (London and Manchester: Sherratt and Hughes, 1905) Price 6s. net.

He rather hopes that this batch of them will make it apparent that they are a part of his method, or, rather, a part of himself; and since they occupy so much space in the book it seems only right that they should appear on his title-page. Possibly the reader is not meant to take them all too seriously, for Mr. Selous warns us that he has not suppressed his errors even when he happened to know them, because, among other reasons, "if one has got in some idea or reflection that pleases one, or a piece of descriptive writing that does not seem amiss, how tiresome to have to scratch it out, merely because it is founded on a wrong apprehension!—the spire to come tumbling just for the want of a base!"

The author rather seems to deprecate being included in the ranks of the ornithologists, his ambition being to make a naturalist who shall use neither a gun nor a cabinet. That is all very well; but to decline to avail oneself of the work done by others is sometimes to miss the clue which would explain some puzzle. If he had handled cabinet specimens, or if he did not "hate the British bird book" so heartily, he might have known why the white lines on the diver's neck shone in such a peculiar way in the sunlight (p. 60), and perhaps would have experienced increased enjoyment in consequence. A theory anent the old puzzle of the puffin and the bunch of fish it brings home in its ornate beak, and some instructive observations on young fulmars, are only a crumb or two out of the good things which we mark in reading many charming pages. One of the illustrations shows birds following the ways of "Nature, red in tooth and claw"; and this (together with that of a herring-gull dealing with a downy puffin) we dedicate to the conversion of those who favour the protection of the larger gulls. We dare not begin to quote for fear of never ending, and must confine ourselves to this one sentence in explanation of the plate: "I saw another kittiwake being savagely murdered by another herring-gull." The chapters on seals are very interesting, for few people have the chance of watching these animals. A good index is a great advantage to the reader, not always found in books of this kind.

FIG. 1.—Oyster-Catchers. From "Nature-Tones and Undertones."

A considerable part of Mr. Boraston's new work is occupied by an account of a remote and little known corner of Anglesey, and it is saying a good deal to say that this is perhaps the pleasantest and most interesting part of the book. How he journeyed there—and back—and what birds and other things he saw is told in the attractive and distinctly original style so much commended in the notices of his former work. Of more highly scientific interest, perhaps, is the series of careful notes which the author made upon a young cuckoo. These include several important observations which must not be detailed here; but we cannot refrain from quoting the author's concluding reflections on the strangely ferocious fledgling he watched so patiently. "And knowing it for a solitary and a wanderer beyond any of its kind, smuggled into life in an alien nest, tended in blind devotion by creatures it requites as blindly by destroying their own offspring; fashioned like a hawk to be hunted by every chit that flies; never to mate, never to nest, never to rear or lead its young; remembering this, I could have wished that this Unnatural Selection had not been, or that this strange mockery of life might be undone." In this chapter, too, we have an interesting inquiry into the theory of the assimilation of the cuckoo's eggs to those of the foster-species, with an analysis of collections of more than seventy nests of various birds containing cuckoos' eggs and the eggs of the foster-parents. The author writes, "The variation exhibited in the collections I have seen was considerable, but I could in most cases have improved the assimilation by transferring the eggs from one nest to another. Unless more convincing evidence were brought forward than such as was furnished by the seventy-six nests mentioned above, I should con-

clude that cases of resemblance between cuckoos' eggs and those of the species in whose nests they are deposited, are due to coincidence rendered possible by a large degree of variation in the former." Although digressions are not announced on the title, the latter is wide enough to cover many things, and many odd bits of out-of-the-way knowledge are woven into this book, which is mainly concerned with birds. A rather bitter attack on game preservers and sportsmen (with a slap at the army dropped in) is sandwiched between some most charming studies of wild life and natural scenery, written in clear and powerful and often quaint and humorous style. When has the barn owl been more aptly described than in this passage? "Never a sound from wing or throat as it flaps or skims in the half-light, watching the ground with its cat's eyes as it goes, until suddenly the silence is startled by a single, rasping yell such as might make the hair stand on the back of every mouse for a quarter of a mile around. The Arch-mouser is on the trail, and such a master of his craft that he appears at times to toot his horn in contempt of his quarry. Or, is this sudden shriek used to start any mouse that may be lurking below, so that when moving it may be more readily discerned?" Mr. Boraston, too, sometimes wants to know why. The eighteen photographs which illustrate this nicely got up volume are almost beyond praise. We have selected this one for reproduction, not because it is by any means the most beautiful, but because of the cleverness with which the whole of this rock, with its seaweed and its oyster-catchers, has been focused; it will appeal strongly to those who love our west coast and its birds. The whole book will be welcomed and treasured up by the great fraternity of British bird-men.

O. V. APLIN.

STUDIES OF CLOUDS.[1]

MR. CLAYDEN'S work will be a standard one for all students of clouds. When the now international classification was first proposed by the late Ralph Abercromby and the present writer, our purpose was to devise a classification for common use at all meteorological stations and in all the navies of the world. It is evident that such a classification must be simple and practicable. A great number of forms must lead to constant errors when used by ordinary observers. Therefore we only proposed the ten types given now in the international cloud atlas.

We were well aware, however, and expressed the view in plain words, that these ten forms are not sufficient for special studies of the transformation of clouds or of the relations between cloud form and weather. For these cases each of the ten great types must be divided into several subspecies, to which proper names must be given.

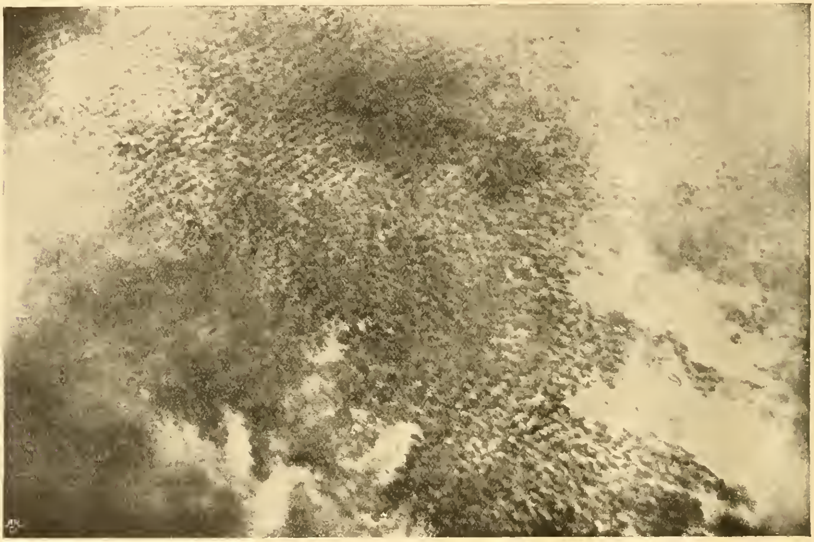

FIG. 1.—Cirro-nebula changing to cirro-cumulus. From "Cloud Studies."

Various attempts have been made to extend the scheme in this way. Abbé Maze in France, Prof. Köppen in Germany, the Rev. F. L. Odenbach in America, and, above all, the Rev. Clement Ley in England, have proposed and defined more detailed classifications; and Mr. Clayden has now in his cloud studies taken a great step forward in this direction.

The descriptions and the illustrations reproduced from photographs are excellent, and everyone who is accustomed to observe the ever-changing panorama of skies will admire the large amount of exact observations given in this book. The book contains reproductions of many typical cloud-forms and certain intermediate forms showing the transformation of one cloud-form into another.

[1] "Cloud Studies." By Arthur W. Clayden, M.A. Pp. xiii+184; 61 plates. (London: John Murray, 1905.) Price 12s. net.

It is important to notice that the author accepts the types of the international cloud atlas and arranges his various forms as subforms of these types. There is, however, one exception. Mr. Clayden does not admit the nimbus cloud as a special type, but puts it under the type stratus. He employs nimbus as an adjective indicating that rain is falling from a cloud. We cannot agree with this plan. Every form of cloud can be transformed into another. It is, indeed, well known that the true typical forms are rare, the majority of clouds being intermediate forms. Of course, it often happens that stratus cloud is transformed to nimbus. The farmer in Sweden says, "if the fog is falling the weather will be fine, if the fog is lifting it comes back as rain." It is really the case that in certain weather conditions the fog follows the upward motion of the air; in the rising air the temperature falls, condensation goes on, and the light fog is transformed to a dense nimbus with rain.

FIG. 2.—High Cirrus (*Cirrus Excelsus.*) From "Cloud Studies."

Nevertheless, there is a vast difference between the fog formed on or near the ground and the true canopy of nimbus cloud rushing forward beneath a layer of alto-stratus in the front of a storm. But here, as always, one form does sometimes pass into another. The alto-stratus does also sometimes sink down and become transformed into nimbus. We know that during summer all low clouds, as a rule, assume more or less the cumulus form. Thus we cannot say that a stratus or an alto-stratus is a nimbus more than that a stratus or a nimbus is a cumulus.

It is not possible to give in this short notice a description of the different forms presented in this book. We must also abstain from an exposition of the author's views regarding the causes which produce the different cloud forms. These views are in most cases highly probable, and in all cases useful hints are given for further investigations. Our purpose now is only to direct the attention of our fellow-students of clouds to a work of the greatest value, which should be studied with the greatest care. No one who desires to study the transformations of clouds or the relation of cloud forms to weather can neglect to consider the valuable results and ideas put forward by Mr. Clayden.

Of course, it is not possible for an international committee or conference to establish a very detailed classification of clouds, but we think it would be very useful if the author would provide the plates and short descriptions as a small atlas for use in observatories and for specialists.

H. HILDEBRAND HILDEBRANDSSON.

TRANSPACIFIC LONGITUDES.

DURING the year 1903 Canada extended the longitude work, carried from Greenwich to Vancouver, across the Pacific to Australia and New Zealand. This was made possible by the completion of the British Pacific Cable—the All Red Line—in the autumn of 1902. The sections of the cable are :—

	Nautical miles
Vancouver to Fanning Island...	3654
Fanning to Suva, Fiji...	2181
Suva to Norfolk Island...	1019
Norfolk to Southport, Queensland	906
Southport to Doubtless Bay, New Zealand...	513

The observers (Dr. Otto Klotz and F. W. O. Werry) were provided with practically identical instruments, the principal ones being the two Cooke transits, of 3 inches clear aperture, and of about 36 inches focal length. Cement or brick piers were built at every station. The observers occupied alternate stations across the Pacific, and as the number of stations is odd, Southport and Doubtless Bay are free from the personal equation, without a direct determination of the latter, although the personal equation was determined. Mr. Werry occupied Fanning and Norfolk,

the writer the other stations, including Sydney, Brisbane, and Wellington for personal equation. At Southport connection was made with the observatories at Sydney and Brisbane, and from Doubtless Bay with Wellington.

It was on September 29, 1903, that the first mutual observations and clock exchange were had with Sydney, and so this night may be considered as the one when for the first time longitude from the west clasped hands with longitude from the east, and the first astronomical girdle of the world was completed.

In making the comparison at Sydney between the longitude brought from the east with that from the west, I have used the value of Prof. Albrecht for the arc Greenwich-Potsdam 0h. 52m. 16·051s., and for the arcs from Potsdam to Madras, *viâ* Teherân, Bushire, Karachi, Bombay, and Bolaram, those of Major Burrard, giving for the longitude of Madras 5h. 20m. 59·235s.

As there has been no re-determination of the various arcs from Madras to Australia, I have adopted the values given in the Australian report of Ellery, Todd and Russell.

Applying these latter to the longitude of Madras, we get for the longitude of Sydney

	h. m. s.		s
	10 04 49	...	0·355 ± 0·088
The Canadian value is	10 04 49	...	0·287 ± 0·058
Difference	... ...	...	0·068

equivalent for the latitude of Sydney to 84 feet. The 1886 value for Sydney is 10h. 04m. 49·54s.

The final values of the Canadian determinations are :—

Final Longitude Values.

Station	Longitude			
	Time	Prob. error	Arc	Prob. error
	h. m. s.	s.	° ′ ″	″
Vancouver . .	8 12 28·368 W.	±0·050	123 07 05·520	±0·75
Fanning . . .	10 37 33·774 W.	±0·054	159 23 26·610	±0·81
Suva	11 53 42·389 E.	±0·055	178 25 35·835	±0·82
Norfolk . . .	11 11 41 146 E.	±0·056	167 55 17·190	±0·84
Southport . . .	10 13 39·782 E.	±0·056	153 24 56·730	±0·84
Sydney	10 04 49·287 E.	±0·058	151 12 19·305	±0·87
Brisbane . . .	10 12 06·044 E.	±0·073	153 01 30·660	±1 09
Doubtless Bay .	11 33 56·146 E.	±0·060	173 29 02·190	±0·90
Wellington . .	11 39 05·087 E.	±0·075	174 46 16·305	±1·12

OTTO KLOTZ.

Ottawa, December 30, 1905.

THE KANGRA EARTHQUAKE OF APRIL 4, 1905.

AFTER a lapse of only eight years since the great earthquake of 1897, India suffered another calamity of the same nature on April 4, 1905, less in violence and extent, but more calamitous in its results, for it claimed a death-roll of 20,000 souls. An interesting preliminary account of this earthquake, by Mr. C. S. Middlemiss, appears in the concluding part of vol. xxxii. of the *Records of the Geological Survey of India*, where the total area over which the shock was felt is estimated at about 1,625,000 square miles, as against 1,750,000 in 1897. The area over which the shock was destructive is smaller in proportion than these figures would suggest, for the isoseist corresponding to 10 degrees of the Rossi-Forel scale includes only 200 square miles, and that corresponding to 8 degrees of the same scale 2150 square miles, as against 300 and 145,000 in 1897. In comparing these figures an allowance must be made for the personal equation, and it seems that, if Mr. Middlemiss's standard had been adopted in 1897, the former of these figures would have been considerably increased and the latter somewhat reduced.

There were two centres of great violence, one near Kangra and Dharmsala, where the tenth degree of the Rossi-Forel scale was surpassed, the other in the Dehra Dun, where the ninth degree was not reached. Between these two the violence was much less, and Mr. Middlemiss points out that the two districts of greatest destruction lie, each, in an embayment of the course of the great boundary fault of the Himalayas; they are the only two irregularities in the generally even sweep of the boundary of the Tertiaries of the sub-Himalayan tract, and as the general effect of the Tertiary, and post-Tertiary, folding and fold-faulting has been to obliterate irregularities in the outline of the mountain-foot, it is natural to suppose that any marked irregularities still left may be in a peculiar state of strain, especially liable to give rise to geotectonic movements. Those which took place on April 4 last seem to have exhausted themselves underground, for no surface faults or changes of level were detected.

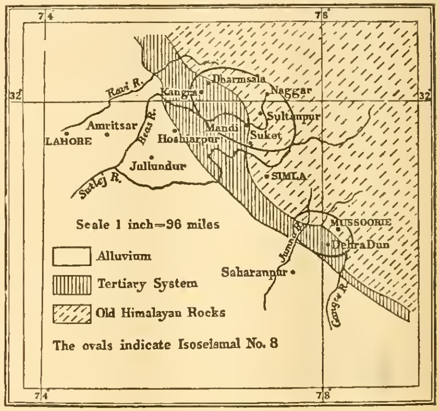

FIG. 1.—Origin of the Kangra earthquake of April 4, 1905.

The nature of the shock seems to have differed from that of 1897, when all accounts agreed in describing it as simple, with only one marked maximum of violence. In 1904 there were, both in the Kangra and Dehra Dun districts, two or three distinct shocks, and we may mention that this is reflected in the long-distance records of the shocks, which indicate at least two distinct impulses, following each other at an interval of a couple of minutes, whereas in 1897 there was no indication of more than a single impulse. The violence of the shock at its greatest seems to have been a little less than in 1897; at Kangra Mr. Middlemiss's observations give the acceleration of wave particle as about 13 feet per second per second, the amplitude as 9·75 inches, and the period as 1·57 seconds. The time of origin, as deduced from local observations, is said to have been 6h. 9m. 0s. Madras time, within a second or two of error; the rate of propagation was 1·95 to 1·98 miles per second as between the origin and the seismograph stations at Bombay, Calcutta, and Kodaikanal, but it must be

remarked that this rate refers to the large motion on the Milne seismographs, not to the felt shock, the discussion of which is deferred to the larger memoir promised.

Among miscellaneous effects of the earthquake it is mentioned that in some cases the flow of springs was more or less completely checked, while others increased or broke out in new places. In Sind and Burma the shock was not felt, but affected the bubbles of level tubes during survey operations, the movement in the former district indicating a surface tilt of about 30 seconds of arc above and below the horizontal, in a north-east-south-west direction.

HENRY JAMES CHANEY.

On February 13 Henry James Chaney, who for more than forty years was an authority on our standards of weight and measure, ended his lengthy official career at Hampstead after a painful illness of some months' duration.

He was born at Windsor in March, 1842, was educated privately, and entered the Civil Service at an early age. In 1860 he was appointed to the Exchequer, the department in which at that time the statutory powers with respect to weights and measures were vested. Here he had the good fortune to come into contact with Airy and Miller, who had just completed their researches, undertaken at the instance of the Government, in connection with the restoration of the Imperial standards. Profiting by their advice and encouragement, he devoted himself with much zeal to the technical duties which were imposed upon his department by the Sale of Gas Act, 1859. Under the direction of H. W. Chisholm, the Warden of the Standards, he took an important part in perfecting the official apparatus for verifying gas-measuring instruments. He acted as secretary to the Standards Commission, 1867–71, and had much to do with the preparation of the voluminous appendices to its reports.

On the abolition of the separate office of Warden of the Standards in 1878, Mr. Chaney was placed in charge of the Standards Department of the Board of Trade. As superintendent of weights and measures he was responsible for the model regulations with respect to weights and measures on which the local regulations throughout the country have been based. He was for many years the representative of the United Kingdom on the Comité International des Poids et Mesures, and took an active share in its proceedings. When the metric system of weights and measures was made permissive in this country in 1897, Mr. Chaney compiled the new tables of metric equivalents which were legalised the following year by Order in Council.

Mr. Chaney's scientific writings are for the most part to be found in the periodical publications of the Standards Department, and include, *inter alia*, "Report on the Standards of Measurement for Gas," "Verification of Standards for the Governments of India and Russia" (1877), "Screw Gauges" (1881–3), "Densities and Expansions" (1883), "Expansion of Palladium," "Re-comparison of the Imperial and Metric Units" (1883), "Verification of the New Parliamentary Standards of Length and Weight" (1881–3). His "Re-determination of the Mass of a Cubic Inch of Distilled Water" (Phil. Trans., 1892), which was intended to serve as a basis for calculating the relation between measures of capacity and volume, gave for the cubic contents of the gallon the value 277·463 cubic inches, a much better approximation than the value 277·274 cubic inches, due to Kater, which was accepted up to that date. The researches which have since been undertaken at the Bureau International des Poids et Mesures, and are still in progress, have yielded a provisional result for the mass of a cubic decimetre of distilled water at its maximum density which leads to the value 277·420 cubic inches for the cubic contents of the gallon. This does not differ much from Chaney's result, and is to be considered as the best determination up to date.

His well known work "Our Weights and Measures," which appeared in 1897, contains a mass of metrological information not readily accessible elsewhere. One of his latest contributions to science was the article "Weights and Measures" in the supplement to the ninth edition of the "Encyclopædia Britannica." His last official publication was a report on the "Construction and Verification of a New Copy of the Imperial Standard Yard" (1905).

His great experience in precise measurement caused him to be regarded as a valuable cooperator, and his advice was frequently sought by official committees. The Imperial Service Order was conferred upon him in 1902, and the services rendered by him in connection with the restoration of the Russian standards of weight and measure were recognised by the present Tsar as well as by his grandfather, Alexander II.

Mr. Chaney's name has long been familiar in metrological circles, and his death has removed another link with the past. The memory of his kindly disposition and ready assistance will be treasured by all those who were in any way associated with him.

NOTES.

We are informed that the council of the Royal Society has selected the following candidates for election as fellows of the society:—Dr. C. W. Andrews, Mr. G. T. Beilby, Mr. F. F. Blackman, Prof. T. J. I'Anson Bromwich, Mr. P. H. Cowell, Mr. W. Heape, Mr. J. H. Jeans, Dr. C. H. Lees, Captain H. G. Lyons, R.E., Prof A. B. Macallum, Mr. J. E. Marsh, Dr. P. Chalmers Mitchell, Mr. J. Swinburne, Prof. H. A. Wilson, Prof. A. E. Wright.

A meeting was held at the Mansion House on Monday, the Lord Mayor presiding, to consider what steps should be taken to commemorate the discovery by Dr. W. H. Perkin fifty years ago of the first artificial colouring matter obtained from a coal-tar product, and to celebrate the great development of the coal-tar colour industry thus started. A note describing the origin and nature of the movement appeared in these columns on February 15 (p. 370). The proceedings at Monday's meeting were opened by Lord Halsbury, who moved:—"That, in view of this being the fiftieth year of the foundation of the coal-tar colour industry, it is desirable that steps should be taken to memorialise the event and to do honour to Dr. W. H. Perkin, the founder." Sir William Bousfield seconded the motion, which was supported by the Master of the Leathersellers' Company and Prof. H. E. Armstrong, and unanimously carried. Lord Rayleigh moved:—"That an appeal be made in this country and abroad for subscriptions for the purpose of carrying out the following objects:—(1) The presentation to Dr. Perkin for his lifetime of an oil portrait of himself, executed by an eminent artist, the portrait to become the property of the nation at his death. (2) The execution of a marble bust of Dr. Perkin to be placed in the rooms of the Chemical

Society. (3) The establishment of a 'Perkin Research Fund' for the promotion of chemical research to be administered through the Chemical Society." This resolution, which was also adopted, was seconded by Sir William Ramsay, and supported by Sir Henry Roscoe and Mr. David Howard. It is unnecessary here to detail the steps in the growth of the German coal-tar colour industry which is the commercial outcome of Dr. Perkin's discovery—an industrial development by which this country might have been expected to benefit. But, as a correspondent writes in the *Times* of February 24:—"Although in this country there have never been wanting capable chemists able to carry on and extend the manufacture of colouring matters, there has been complete lack of understanding on the commercial side of the complex requirements of the industry and complete lack of sympathy between the capitalist and the scientific worker. The failure must be credited to our universities and to our faulty system of higher education—to our inbred Philistinism. Little, if anything, has been done either in school or university to evoke in the community even an elementary understanding of the principles of science and of their application to commerce and industry. We are now paying the penalty of our neglect." To secure that the nation shall derive full industrial value from scientific discoveries will be possible only when we have developed a system of secondary and higher education in which modern needs and modern methods are recognised; for not until then will there be among us a generation of employers and capitalists able to understand expert opinions and with scientific imagination enough to read the signs of the times.

THE encroachments of the sea on parts of our coasts, and the question of national responsibility for the protection of the seaboard against such erosion, was raised in the House of Commons on Monday in an amendment to the Address. Several members urged that the Government should give financial assistance for the construction of works for coast protection and afford facilities to local authorities for obtaining loans on easy terms for the defence of the sea coast. The President of the Board of Trade stated that the Government has decided to have an inquiry in the form of a Royal Commission, which will extend not merely to coast defence, but to two or three other kindred subjects, such as waste lands and probably afforestation. A Commission will be appointed at an early date to inquire into the matter. Some objections to the expenditure of Imperial funds upon the protection of private property at sea-side resorts and other localities were stated in an article in NATURE of February 15 (p. 309).

SEVERAL years ago a commission was appointed by the Imperial Academy of Sciences of Vienna to collect phonographic records to be preserved for scientific study. Some of the results obtained by expeditions to Kroatia, Slavonia, and Lesbos were described in NATURE of January 29, 1903 (vol. lxvii., p. 301). The Vienna correspondent of the *Pall Mall Gazette* now states that from North Tyrol and Vorarlberg fifty-seven specimens of German dialects have been obtained for the archives, and another forty-seven from Carinthia. From New Guinea have been sent thirty-two phonographs recording the language and music of the natives, with especially interesting war songs and the accompanying drum music. From India have been received valuable records of old Sanskrit songs. An expedition which was sent out to Australia is now on its way back, and another party is about to start for Greenland.

IT is stated that the new director of the Vatican Observatory will be Father J. G. Hagan, S.J., professor of astronomy in Georgetown University, U.S.A., and director of the observatory there.

IN connection with the indication by the London County Council of houses in London which have been the residences of distinguished individuals, a memorial tablet was erected on Monday on No. 110 Gower Street, where Charles Darwin resided from 1839 to 1842.

MR. E. T. WHITTAKER, F.R.S., has been appointed Andrews professor of astronomy in the University of Dublin, in succession to the late Prof. C. J. Joly, F.R.S. The appointment carries with it the office of Royal Astronomer of Ireland.

A REUTER message from Paris states that the committee of the Alliance Française-Britannique received at the Sorbonne on Monday the delegates of the London branch of the Alliance, headed by Sir Archibald Geikie, F.R.S., the chairman. M. Liard, Vice-Rector of Paris University, and M. Levasseur, director of the Collège de France, and honorary president of the Alliance Française, welcomed the British delegates. After Sir Archibald Geikie had delivered an address on geology, the British guests visited the laboratory and the large amphitheatre of the Sorbonne. In the evening they were present at a banquet given in their honour, the Minister of Public Instruction being in the chair.

WE learn from the *British Medical Journal* that the next meeting of the Congress of Experimental Psychology will be held at Würzburg, April 18–21. Among the communications promised are the following:—Dr. F. Krüger, on the relations between experimental phonetics and psychology; Prof. O. Külpe, on the present position of experimental æsthetics; Dr. F. Schumann, on the psychology of reading; Prof. R. Sommer, on psychiatry and the psychology of the individual; Dr. W. Weygandt, on the psychological investigation of congenital feeble-mindedness. Communications relative to the congress should be addressed to Prof. O. Külpe, Würzburg.

ABOUT two years ago steps were taken to erect a fitting memorial to James Watt at his birthplace. This is to take the form of a commemorative public building and statue at Greenock. In the *Engineer* of February 23 disappointment is expressed that an object so obviously worthy, and an appeal so influentially prosecuted, should not have had greater success. Only 700*l*. has been subscribed in Great Britain and 190*l*. in America. Influential canvass, nevertheless, was made by Mr. Carnegie in the United States, while in Great Britain Dr. Robert Caird sent out 10,000 circulars inviting subscriptions. The balance required, 9300*l*., has been contributed by Mr. Carnegie.

ORNITHOLOGY has lost its oldest votary by the death, on February 20, of Prof. Jean Louis Cabanis, for many years in charge of the collection of birds in the Museum of Berlin. Born in 1816, his earliest work of importance seems to have been the ornithology of Tschudi's "Fauna Peruana" in 1845 and 1846. He afterwards did the same service for Sir Richard Schomburgk's "Reisen im Britisch-Guiana"; but the "Ornithologische Notizen" in the *Archiv fur Naturgeschichte* for 1847 almost marked a new epoch in the progress of the science, for they were written in conjunction, it may be said, with Johannes Müller, and practically applied the principles of taxonomy laid down by that great anatomist, in his contributions to the Academy of Sciences in Berlin in 1845 and 1846, On certain variations in the vocal organs of the Passeres—

a line of investigation so well worked out subsequently in this country by Garrod and Forbes. In 1853 Cabanis established the *Journal für Ornithologie*, of which he remained editor until succeeded in 1893 by his son-in-law, Prof. Reichenow, and with that journal—the prototype of the *Ibis*, and hence of several others—his name will be ever associated. The "Museum Heineanum" is another work by which he will be remembered; but the above-mentioned "Ornithologische Notizen" must be regarded as by far his greatest performance, and, of course, they excited no attention in this country for many years.

MR. MORTEN P. PORSILD informs us that during the summer of the present year a permanent station for the study of Arctic science will be established on the south coast of Disco Island, in Danish West Greenland. The cost of the foundation is to be defrayed by a gift from Mr. A. Holck, of Copenhagen, and the Danish Government has promised an annual grant of 600*l.* towards its maintenance. A laboratory, equipped with appliances and instruments, especially for biological researches, will be attached to the station, and work-places will be furnished for visiting naturalists, foreign as well as Danish. The establishment of two such places is contemplated at present. The visitors will be allowed free use of instruments, travelling outfit, and library of the station; lodging will be free, and a small fee only will be charged for board. The first visitors will be received in 1907, and notices, inviting application, will be issued in due course. A library of Arctic literature is to be founded at the station, and is to be made as complete as possible. Mr. Porsild, the leader of the station, whose address until May 1 next is Copenhagen, S., Denmark, will be glad to receive presentation copies of works on Arctic and Antarctic subjects, especially on Arctic biology, for addition to the library.

MR. BALFOUR proposed the toast "The School and Union" at the annual dinner of the Students' Union of the London School of Economics and Political Science held on February 24. Answering the question, What is it we mean by economics in its wider sense? Mr. Balfour spoke of the scientific character of the study of economics, and went on to say:—"Science, if it means anything, means a progressive knowledge, and I confess I detest the habit of the unreasoning appeal to authority, especially when, as is often the case, the authority is somewhat antiquated. In science there is, or ought to be, no such thing as authority whatever. A man of science builds, and gratefully builds, on the foundations left by his predecessors; but they are but foundations. It is his business to raise tier after tier the fabric of ever-progressive knowledge." Later Mr. Balfour said he desired to see the school "inspired with that detached and disinterested scientific spirit which is, after all, the true origin of all progress in this world." We note with pleasure this frank recognition of the value of the scientific spirit in all branches of learning and in every department of enterprise by a great politician, and we look forward to the time when every human activity in this country will be governed by the methods of science and imbued with its spirit.

DURING the past few days the following reports of seismic disturbances have appeared in the daily papers:—*February* 21.—Shemakha (Government of Baku), Earthquake was felt at 12.10 a.m. Fort de France, Earthquake shock was felt at 12.13 p.m. St. Lucia, Severe earthquake occurred at 8.30 p.m. Other shocks were afterwards felt at frequent intervals. Mont Pelée, Martinique, is active. At Fort de France many houses have been demolished by earthquakes. La Soufrière, the St. Vincent volcano, is more active than it has been since 1902. Buenaventura, Colombia, Earthquake lasting seven minutes occurred at 10.35 a.m., the movement being from north to south. After the earthquake there was a huge wave, which was of no consequence at Buenaventura; but according to reports from the coast so far as 50 leagues to the south, 2000 persons were killed by falling houses or drowned by the wave, whole families being lost.

ACCORDING to the *Chemiker Zeitung*, the General Electrical Company, of Berlin, in conjunction, it is said, with the firm of W. C. Heraeus, of Hanau, intends to start a company for the production of mercury lamps made out of quartz glass.

ON February 10 Prof. van 't Hoff gave a lecture on thermochemistry before a large gathering of members and guests of the Austrian Engineers' and Architects' Society in Vienna. After a few preliminary remarks on the heat of reaction and combination of chemical substances and their calorimetric measurements, Prof. van 't Hoff dwelt upon the heat of alcoholic fermentations, of thermite decomposition and of various illuminants, pointing out the great amount of heat developed in the decomposition of acetylene and the pressure developed in explosions, and finally discussed the relations between heat development and chemical affinity, referring at length to Berthelot's principle, which would find a measure of chemical affinity in the heat developed, but which Prof. van 't Hoff declared untenable. The lecturer concluded with the remark that this subject of thermochemistry was one in which a more general application of modern chemistry was most desirable; he was, however, of the opinion that it was the duty of the man of science to seek out new ways and to find out new laws, but that here his duties ceased, whilst the practical technical man must himself sort out that which was necessary and usable. After the lecture the leading chemists and physicists of Vienna entertained Prof. van 't Hoff to a dinner given in his honour.

As was mentioned in NATURE of February 1 (p. 322), the sixth International Congress of Applied Chemistry will be held this year in Rome from April 25 to May 3. It may be remembered that the first congress was held in Brussels in 1894, the second in Paris in 1896, the third in Vienna in 1898, the fourth in Paris in 1900, and the fifth in Berlin in 1903; a desire has been expressed that the seventh meeting should be held in England. All communications and applications for membership of the sixth congress should be addressed to the Ufficio del Congresso, Via Panisperna, 89, Rome. The subscription fee of 20 lire is to be forwarded by P.O.O., made payable to Prof. Giovanni Giorgis, the treasurer of the congress. Upon application a pamphlet will be forwarded containing all information requisite for applicants, together with the regulations of the congress, a list of Italian and foreign committees, a list of the sections, and the titles of papers and communications that have been announced up to the present. The English committee contains some thirty-three names of representatives of fifteen leading scientific societies connected with chemistry, including the Royal Society, the Chemical Society, Society of Chemical Industry, Society of Public Analysts, the Iron and Steel Institute, the Faraday Society, the Institute of Chemistry, &c. In addition to the sectional meetings, which are to take place on April 27, 28, and 29, and on May 1 and 2, lectures of a general nature will be arranged (such lectures by Profs. H. Moissan, Sir W. Ramsay, and O. N. Witt

are announced), a social gathering of the members will take place on the evening of April 25, an excursion in the neighbourhood of Rome will be made on Sunday, April 29, and two alternative excursions, the one to Sicily and the other to the Island of Elba, to places of chemical interest on May 3; as the number of participators in the latter is limited, preference will be granted to those who are first to send in their names, and more especially to foreign members. Members may further obtain a reduction of 40 per cent. to 60 per cent. on the Italian State Railways, and 60 per cent. on tickets issued by the navigation companies Navigazione Generale Italiana and La Veloce. The papers to be contributed will be grouped in eleven sections, and may be in one of the four official languages of the congress, namely, Italian, French, German, and English. The discussions after the reading of the papers may also be carried on in one of these languages.

Museum News for February records the addition to the Brooklyn Museum, New York, of a skeleton of the sperm-whale, measuring 47 feet in length, which has been suspended to the roof of the building.

In the *American Journal of Science* (February) Mr. C. C. Trowbridge re-opens the disputed question of the interlocking of the emarginate primary flight-feathers in raptorial birls, adducing apparently conclusive evidence that this takes place in certain American hawks, with a resulting increase of wing-power.

The contents of vol. lxxx., part iv., of the *Zeitschrift fur wissenschaftliche Zoologie*, comprise a paper by Dr. E. Strand, of Christiania, on the structure and development of spiders; a second, by Mr. J. Wilhelmi, on the excretory organs of the fresh-water turbellarian flatworms of the section Tricladida; and a third, by Dr. C. Hennings, of Rostock, on the "tömövarysche" organ in myriapods. The latter is the continuation of a paper the first part of which appeared in the same journal in 1904. A systematic classification of the myriopods is given.

In the report of the Maidstone Museum, Library, and Art-Gallery for 1905 is published a photographic reproduction of an original drawing by the late Mr. W. H. Bensted of the well known slab (now in the Natural History Museum) containing a large portion of the skeleton of a young iguanodon, obtained by him from the ragstone quarry in Queen's road, Maidstone, in 1834. The drawing is, of course, mainly of historical interest. An offer of the loan, for an indefinite period, of an exceedingly valuable, and in this country almost unique, collection of Japanese pottery, made by the Hon. H. Marsham, has been accepted by the museum authorities.

The January issue of the *Emu* contains an excellent portrait of the late Captain F. W. Hutton. From the report of the proceedings of the fifth session of the Australasian Ornithologists' Union, held at Adelaide, which appears in this number, we learn that the acting president devoted his address to the subject of European and other birds introduced into Victoria. The two species that have thoroughly established themselves are the starling and the sparrow. No one appears to have a good word for the latter, but as regards the former it is stated that the residents in Riverina are longing for its arrival in numbers to help them to cope effectually against the armies of locusts and caterpillars that frequently infest those districts. Thrushes, blackbirds, and greenfinches have established themselves to a small extent in and around the districts where they were first liberated, but chaffinches, yellow-hammers, and siskins have practically failed to accommodate themselves to their new surroundings.

In discussing the early stages of the Palæozoic rugose corals, as a clue to the origin and relationships of the group, Mr. C. E. Gordon, in the February number of the *American Journal of Science*, finds himself unable to accept Mr. Duerden's views as to the close connection between the ancient tetrameral and the modern hexameral types of corals. On the contrary, he is of opinion that we are not yet in a position to define their relationships or to state which is the earlier of the two. In a second paper in the same journal Mr. C. R. Eastman discusses the affinities to the lung-fishes presented by the group of armoured Palæozoic fishes typified by Coccosteus, and commonly known as the Arthrodira. From the study of the North American genera Dinichthys, Dinomylostoma, &c., the author comes to the conclusion that the alleged relationship is well founded, thus confirming the views of Dr. A. Smith Woodward. The author goes, however, somewhat further, and urges that while the living Australian *Ceratodus* (*Neoceratodus*) *fosteri* bears an intimate relation to Arthrodira on the one hand, and to the Palæozoic Dipterus and its allies on the other, yet that it is a more primitive type than any of these. It represents, in fact, the direct line of descent from primitive Palæozoic Ceratodonts, from which Dipterus and its allies diverged in one direction and the Arthrodira in the other. Hence the Dipnoi cannot be descended from the crossopterygian ganoids, but are more probably derived from Pleuracanthus-like sharks. Further, the association of the Arthrodira with the Ostracophora (Pterichthys) in one group, Placodermata, becomes obviously impossible. Mr. R. S. Lull points out that the name Ceratops proposed by Marsh for the Laramie horned dinosaur is preoccupied, and he accordingly suggests the new name Proceratops, with Agathaumidæ as the family title.

The *Pioneer Mail* remarks that the immunity of Europeans continues to be one of the most noticeable features of the plague epidemic. Last year, in the Bombay Presidency, where the disease carried off more than a quarter of a million people, only nineteen Europeans in all were attacked, of whom ten died. In the previous year, in the same region, where 316,000 deaths took place, only eight were amongst Europeans.

Mr. A. Elenkin, writing in the *Bulletin du Jardin impérial botanique*, St. Petersburg (vol. v., part v.), on the marine algæ found near the biological station at Mourmane, discusses the different forms of Lithothamnin, and describes a new species characterised by the development of bicellular spores.

In recording his impressions of the botanical congress at Vienna in the *Bulletin de l'Académie de Géographie botanique*, Mr. L. Navas, who represented the Société Aragonaise des Sciences naturelles, presents his arguments in favour of giving the authority for the genus and not the authority for the binomial name of a plant.

A periodical bulletin—*Le Bambou*—devoted to the study of the bamboo, its cultivation and uses, has been started by Mr. J. H. de Lehaie, Mons, Belgium. The first number, published January 15, contains an article on the flowering and seeding of bamboos in Europe. From a study of the collated data, the writer concludes that in the section Arundinaria the majority of species flower gregariously, produce seed and die, but in the case of Phyllostachys the production of seed does not appear to be the harbinger of death.

IN addition to the descriptions of a number of Indian forest fungi that Dr. E. J. Butler has been contributing to the *Indian Forester* (October to December, 1905), some of his remarks possess a more general interest. In connection with the genus Chrysomyxa, a heterœcious species in Europe produces teleutospores on rhododendrons and æcidia on the spruce. In India, both æcidial and teleuto stages of a Chrysomyxa have been found on *Rhododendron campanulatum*, thus giving grounds for an assumption that Chrysomyxa was originally confined to a single host. Dr. Leather also makes some definite statements on the subject of wheat rust, *Puccinia graminis*, and the æcidial stage that occurs on the barberry. In India, the stages on the wheat do not seem to depend upon the presence of barberry bushes, as the most destructive areas of rust were hundreds of miles distant, and, further, at the only part of the Himalayan range where *Accidium berberidis* is known to occur black rust is extremely rare on cereals.

IT has always been recognised that there is an uncertainty as to the plant that yields the Manila Elemi of commerce. Trimen and Bently, in "Medicinal Plants," referred it to a species of Canarium allied to *Canarium commune*, and later writers have generally referred it to that species. Mr. E. D. Merrill, the botanist in the Philippine Islands, with specimens before him of fruit, flowers, and the pitch locally known as "brea," assigns it to *Canarium luzonicum* in Publication No. 29 of the Bureau of Government Laboratories. Other species of Canarium yield brea, but, according to the writer, do not furnish the article of commerce. The same publication contains the third list of new or noteworthy plants that Mr. Merrill has identified. It includes a number of new species of Medinilla and Rhododendron; of the fourteen species of Rhododendron, thirteen are believed to be endemic.

IN a note contributed to the *Atti dei Lincei*, xiv. (2), 12, Dr. G. Noè discusses the functions of the remarkable organs of sense first discovered by Hicks in 1857 on the wings of many species of Diptera.

IN the *Memorie* of the Italian Spectroscopists' Society, xxxiv., 6, Messrs. A. Mascari and A. Cavasino discuss the effect of atmospheric disturbances on the outline of the sun's disc, with special reference to the direction of the wind and other meteorological conditions.

MEMBERS of the recent British Association party will remember enjoying English salmon for dinner one day on the voyage home from Beira. This reminiscence is suggested by a note in the *Revue générale des Sciences* from which we learn that an undertaking has successfully been carried out for obtaining in Paris fish from the French fisheries on the west coast of Africa, transported under cold storage.

IN connection with Prof. Sydney Hickson's article on "Miners' Worm" (February 8, p. 344), attention may be directed to a paper by Gino Peri in the *Atti dei Lincei*, xiv. (2), 12, dealing mainly with the question as to how far *Ankylostoma duodenale* is parasitic on animals other than man. The author has succeeded in infecting dogs through the mouth and by penetration of the skin, and there are good reasons for believing that horses are also liable to infection.

M. GEORGES CLAUDE describes in the *Journal de Physique* a series of apparatus for the separation of oxygen and nitrogen by the liquefaction of air. In these the necessary degree of cold is obtained by expansion accompanied by performance of external work, and the process of separation depends on the small difference between the boiling points of oxygen and nitrogen. The whole apparatus is of a compact form, and of two examples in actual working at Boulogne-sur-Seine, one is capable of generating 700 and the other 1000 cubic metres of 96 to 98 per cent. oxygen per diem.

THE *U.S. Monthly Weather Review* for September last contains a graphic account of a tornado of marked severity which visited Carbondale, Pennsylvania, on August 30, 1905. Mr. W. M. Dudley, meteorologist in charge at Scranton, about sixteen miles distant, issued a circular of inquiry, and obtained special reports from neighbouring districts. From these it appears that a funnel-shaped cloud, from which vivid lightning played, moved across the northern portion of Carbondale in a south-west to north-east direction, covering a track two miles in length and from 25 to 200 yards in width. About thirty houses and other buildings were blown down, and some of the roofs were carried to a distance of 600 feet. The trees which were blown down fell to the eastward. The area affected was, as usual, very small, the storm being chiefly confined to the Carbondale district. At Scranton there was

FIG. 1.—A building which was moved in line with the direction of motion of a tornado on August 30, 1905.

vivid lightning, but no other special characteristics were observed; the barometer was low, reading 29·64 inches, but remained steady; there was no noticeable increase in the wind velocity, and very little rain fell. The passage of the cloud, which appeared to revolve in a backward direction, was accompanied by a heavy rumbling noise. The illustration, from one of the photographs taken, shows the effect of the storm on the buildings; the tornado occurred about 8h. 30m. p.m., but its duration is not stated.

M. CH. ED. GUILLAUME contributes to the *Revue générale des Sciences* for January 15 an interesting account of the career of Colonel Charles Renard, whose death took place in April of last year. From a popular point of view, Colonel Renard sprang into fame in 1884–5 in connection with the successful trips made by the navigable balloon *La France*; but his scientific work covers a wider range than this series of experiments, his inventions dating from 1875, when he devised a new air-valve for balloons, up to within a short time of his death. Among other innovations we notice the introduction of the coefficient of

"laminage" in connection with problems of thermal conductivity between gases and solids; also improvements in the construction of boilers and surface condensers based on the same study, having for their object the construction of light motors for aërial navigation. Then, again, we find Renard turning his attention to portable hydrogen generators for military ballooning and pneumatic elevators for grain and other materials. Last, but not least, we have the motor train, exhibited in December, 1903, all the carriages of which were self-propelled by power transmitted from the motor through a series of jointed shafts. This train was successfully conducted round sharp corners through the streets of Paris.

The February number of *Symons's Meteorological Magazine* commences the forty-first volume of this useful periodical. It began as a two-page "Rain-circular," intended to keep rainfall observers in touch with each other's work; in 1866 it became an eight-page magazine, and has now gradually increased to twenty pages, and has attained, under the editorship of Dr. H. R. Mill, to the position of one of the most important monthly meteorological reviews published. Dr. Mill points out that the readers of the magazine frequently tender advice; although this cannot always be adopted individually, he has endeavoured to give effect to the principal desiderata put forward during the last few years. The chief result has been the introduction of a very useful additional table of fifty-four rainfall stations, giving the position and height above sea, and the statistics of rainfall and temperature for each month; it shows the value and date of the maximum and minimum temperature, and the number of nights at or below 32°, both in the shade and on the grass; the thirty years' average and the actual rainfall for the month, the greatest fall in twenty-four hours, and the number of rainy days, together with the mean annual fall. Following numbers will show, somewhat like the Weekly Weather Report of the Meteorological Office, the total rainfall from January 1 to the end of the month dealt with. This new table involves a considerable amount of additional labour, but greatly enhances the value of the publication.

A very interesting article on the uranium deposits of St. Joachimsthal is contributed by Dr. Paul Gaubert to No. 1 of vol. iii. of *Le Radium*. The article is illustrated by geological maps of the district and of the mines, and by two photographs of the town. The same number of *Le Radium* contains also a *résumé*, by Prof. G. Sagnac, of the experimental methods used in the study of the transformation of Röntgen rays.

The report of the International Committee on Atomic Weights for 1905 is published in the Proceedings of the Chemical Society (vol. xxii., No. 303). During the past year there was unusual activity in the determination of atomic weights, and some of the work done relates to the most fundamental values. The entire system of atomic weights is thus affected more or less profoundly, and a general revision would seem to be needed in the near future. In particular, the recent re-determinations of the atomic weights of chlorine, sodium, and nitrogen appear to show that the values obtained by Stas for these elements are now no longer tenable. Guye's work in connection with nitrogen has already been noticed in Nature (vol. lxxiii., p. 37). The other elements of which the atomic weights have been re-determined are cadmium, carbon, gadolinium, iodine, potassium, silicon, strontium, tellurium, and thorium.

Some interesting results have been obtained by Mr. Percival Lewis in studying the degree of ionisation in the gases resulting from coloured flames (*Physical Review*, vol. xxi., No. 6). The specific ionic velocity was measured in the case of a Bunsen flame into which solutions of known concentrations of various salts of the alkalis and alkaline earths were sprayed. The ionic velocity apparently varies in the case of each salt inversely as the square root of its concentration in the flame; the specific ionic velocity has, moreover, the same magnitude for ions of the same sign from equimolecular solutions of all the salts of all the alkali metals. The velocity of the negative ions is always somewhat greater than that of the positive ions. The measurements given show also that the rate of re-combination of the ions from the colourless Bunsen flame is much greater than that observed in the case of the coloured flames.

Prof. Henri Moissan in a recent paper gave an account of his experiments on the fusion and distillation of metals of the platinum group. In the current number of the *Comptes rendus* (February 19) he describes similar experiments on the metals of the iron group, the metals examined including nickel, iron, manganese, chromium, molybdenum, tungsten, and uranium. All these were distilled in the electric furnace, but the boiling points varied considerably. The most volatile proved to be manganese, which distils readily before the lime of the furnace is volatilised. Nickel is fairly easy to distil, then chromium, which distils with regularity under the action of a current of 500 amperes at 110 volts. Iron offers difficulties, on account of the dissolved gas causing foaming at the commencement of distillation, but with a current of 1000 amperes at 110 volts 400 grams of iron distilled in twenty minutes. The boiling point of uranium is higher than that of iron. The greatest difficulty was experienced with molybdenum and tungsten; the latter metal, with a current of 500 amperes at 110 volts, showed no signs of fusion in five minutes; even when the current was raised to 800 amperes only 25 grams could be distilled in twenty minutes.

Dr. G. H. Fowler desires it to be known that the Marseilles Exhibition of Oceanography and Sea Fisheries has not been "postponed," as stated in a circular issued by the British Commission of the Milan Exhibition. No postponement of the Marseilles Exhibition has been contemplated, though H.M. Treasury has refused financial support.

Messrs. Sampson Low, Ltd., have just published the eighth edition of Mr. W. T. Lynn's "Remarkable Eclipses" and the thirteenth edition of his "Remarkable Comets." Each book, though it contains only about fifty pages, gives an interesting and accurate statement of the main facts of the subject with which it deals.

The Country Press, Ball Street, Kensington, W., has issued a series of seven pictorial post-cards on which are shown in an effective manner forty-two species of British ferns. The idea is a good one, and should serve to direct the attention of young people to the beauties of this branch of plant life. Other natural objects are to be dealt with in a similar manner in future series of post-cards.

We have received a copy of the thirty-seventh annual report of the Wellington College Natural Science Society, that, namely, for 1905. It is quite clear that the society's activity has in no way diminished. The open Saturday meetings provide the boys of the school with excellent fortnightly lectures, the subjects of which are by no means

exclusively scientific. The meteorological record is as exhaustive as ever, and some reproduced photographs included in the report show that the photographic section is doing good work.

THE Cambridge University Press has published a third edition of "Hydrodynamics," by Prof. Horace Lamb, F.R.S. The second edition of this standard work was reviewed at length in NATURE of November 21, 1895 (vol. liii., p. 49). In the present issue no further change has been made in the general plan and arrangement of the first edition, but the work has been carefully revised, occasional passages have been re-written, and many interpolations and additions have been made, amounting in all to about one-fifth of the whole.

MR. S. HIRZEL, Leipzig, has commenced the publication of a new and elaborate work entitled "Handbuch der anorganischen Chemie," edited by Dr. R. Abegg, assisted by many leading workers in chemistry—particularly physical chemistry—in Germany and elsewhere. The second part of vol. ii. has recently been issued, the title being "Die Elemente der zweiten Gruppe des periodischen Systems." The first part of this volume has not yet appeared, but the first part of the third volume will be published in the spring of this year. We propose to notice the work when the volumes have been completed.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN MARCH :—

March 1. 6h. 14m. to 7h. 9m. Moon occults f Tauri (mag. 4·3).
,, 2. 6h. 41m. to 7h. 45m. Moon occults γ Tauri (mag. 3·9).
,, ,, 8h. 5m. Minimum of Algol (β Persei).
,, ,, 11h. 51m. to 12h. 40m. Moon occults θ^1 Tauri (mag. 3·9).
,, ,, 12h. 3m. to 12h. 31m. Moon occults θ^2 Tauri mag. 3·6).
,, 11. 16h. 11m. to 16h. 59m. Moon occults γ Virginis (mag. 3·0).
,, 12. 6h. 21m. to 8h. 31m. Transit of Jupiter's Satellite III. (Ganymede).
,, 14. 17h. 22m. to 18h. 23m. Moon occults γ Libræ (mag. 4·1).
,, 15. Venus. Illuminated portion of disc = 0·993; of Mars = 0·962.
,, 18. 5h. Mercury at greatest elongation (18° 31′ E.).
,, ,, 10h. 34m. Transit (ingress) of Jupiter's Satellite III. (Ganymede).
,, 19. 12h. 58m. Minimum of Algol (β Persei).
,, 21. 1h. Sun enters Aries. Spring commences.
,, 22. 9h. 47m. Minimum of Algol (β Persei).
,, 29. 10h. Jupiter in conjunction with Moon (Jupiter 4° 32′ N.).
,, ,, 20h. 56m. to 21h. 35m. Moon occults α Tauri (Aldebaran, mag. 1·1).

COMET 1906*a* (BROOKS).—A further extract from Herr M. Ebell's ephemeris for comet 1906*a*, as published in No. 4075 of the *Astronomische Nachrichten*, is given below :—

Ephemeris 12h. M.T. Berlin.

1906		α (true) h. m. s.		δ (true) ° ′		log r		log Δ		Brightness

This comet is now travelling nearly due south towards the constellation Auriga, and will apparently pass between Capella and β Aurigæ, nearer to the latter, on about March 21.

COMET 1905*c* (GIACOBINI).—Comet 1905*c* has now become so faint as to be beyond the reach of the naked-eye observer. On March 3 it will be only a little brighter than at the time of discovery, and will set just before 9 p.m., or about three hours after sunset, slightly to the south of west.

An extract from Herr A. Wedemeyer's daily ephemeris, as published in No. 4074 of the *Astronomische Nachrichten*, is given below :—

Ephemeris 12h. M.T. Berlin.

1906		α (true) h. m. s.		δ (true)		log r		log Δ		Brightness

From this it will be seen that the comet is now apparently traversing the constellation Cetus, and will be about 1° due north of the wonderful variable Mira on the evening of March 7.

A number of full notes of the observation of this comet at the Arcetri Observatory, between December 11 and 31, 1905, are given by Signor A. Abetti in No. 4073 of the *Astronomische Nachrichten*.

LIFE OF PIETRO TACCHINI.—We have received an interesting short biography of Prof. Tacchini, written in Italian by Signor L. Palazzo, who evidently knew the great Italian astronomer intimately, and appreciated his works. The brochure contains nine pages of text and a fine reproduction of Tacchini's portrait; it is published by the Typographical Society of Modena.

SUN-SPOT SPECTRA.—A valuable paper on the spectra of sun-spots is published in No. 1, vol. xxiii., of the *Astrophysical Journal* by Profs. Hale and Adams. The "widened lines" given in the table accompanying the paper number 345, and were measured on ten photographs —including three separate spots—taken with a grating spectrograph in connection with the Snow telescope of the Mount Wilson Solar Observatory.

The region measured was from λ 5000 to λ 5853, and, in a second table, the wave-lengths of a number of "bands" shown in the spot spectrum are also given.

The discussion of the results is extremely interesting, but is too lengthy to be even summarised here. It may be remarked, however, that the lines of titanium showed the greatest mean change of intensity, and that all the silicon lines in the region considered were much weakened.

Reproductions of some of the photographs obtained accompany the paper, and show the widened lines very clearly.

"THE HEAVENS AT A GLANCE."—This well known card calendar reaches its tenth year of issue with the present (1906) copy, which contains the usual data and notes. As in former years, we can only remark that it will be found to be a very handy and useful source of reference to everyone engaged in observational astronomy.

The calendar may be obtained from its author, Mr. A. Mee, Tremynfa, Llanishen (near Cardiff), for sevenpence, post free.

THE LANDSLIDE IN THE RHYMNEY VALLEY.

THE principal source of the Rhymney River is a copious spring in which the rain-water that has disappeared into numerous swallow-holes, and flowed for some distance underground in the Mountain Limestone, again rises to the surface near the edge of the Millstone Grit. From this point the incipient river flows in the direct line of dip of the strata, that is, in a south-south-easterly direction, across the outcrops of the Millstone Grit, the Lower Shale series, and the Pennant Sandstone series of the South Wales Coalfield. The length of its course on the Millstone Grit is nearly two miles, and on the Lower Shale series five miles.

The Brithidir—in some parts called the Tillery—seam of coal constitutes the dividing plane between the Pennant Sandstone and the Lower Shale series.

In a section taken at right angles across the valley at the point where the landslide—the subject of the present notes—is taking place, that is, about one and a half miles higher up the stream than the point at which the Brithidir seam dips under it, the bottom of the valley is 750 feet wide and 700 feet above sea-level; the outcrops of the Brithidir seam are 3000 feet apart and 1000 feet above sea-level, and the summits of the Pennant Sandstone are about one and a half miles apart and 1300 feet above sea-level. The average inclination from the outcrop of the seam to the bottom of the valley on each side is thus approximately 1 in 4.

Above the outcrops of the seam the ragged edges of the sandstone escarpments are seen projecting above the accumulations of débris which hide their bases; below the outcrops a superficial, grass-grown deposit, partly perhaps of Glacial origin, consisting of earth, clay, sand, and stones, probably not more than from 10 feet to 20 feet thick at any point, and possibly thinner in many places, lies upon and entirely conceals the shales. Part of this deposit, having a width of between 2000 feet and 3000 feet measured along the line of the valley, is known to have been slowly moving down the western slope ever since the Rhymney Railway was constructed across it, near the bottom of the valley, some fifty years ago. The excessive slowness of its general motion is shown by the following facts:—first, the railway, together with a stone bridge over it, has only been carried to a distance of from 6 feet to 10 feet eastwards from its original position during the whole of that long period of time; secondly, the arch of the bridge, which, although damaged and partially distorted, was prevented from being entirely broken up by placing heavy balks of timber between its side-walls under the level of the rails, was only removed, and replaced by a girder bridge, three years ago; lastly, the river, which flows at the foot of a steep bank, not far from the railway bridge, has retained its old channel, and has been able to carry away the débris from the foot of the moving bank sufficiently fast to prevent the latter from invading its bed.

Although the general movement of the ground is so slow and uniform that the roads and fences, and the vegetation which grows upon the surface, give no clue as to what is taking place over the greater part of the affected area, there are local indications here and there which show that a number of smaller and comparatively rapidly moving landslides have occurred within the larger area from time to time. One of these smaller landslides recently damaged the village of Troedyrhiwfuwch, situate near the upper end of the moving slope. This village consists of a public house, a school-room, and two rows of twenty or thirty houses, built upon the opposite sides of a road which runs parallel to the valley at a height of about 200 feet above the river. The pine-ends of many of the houses, in the row nearest the centre of the valley, appear to have lately undergone substantial repairs, and the public house has been entirely re-built, with its foundations, it is said, now resting on the solid rock. The gardens of the houses nearest the northern end of the row now under consideration, together with the division walls between them and the outhouses contained in them, have been ruined beyond repair, and part of the ground on which the gardens were formed has been broken and piled up behind the houses like the front of a wave advancing down the slope, and appears to be still moving.

In this part of the coalfield, as well as over practically the whole of Monmouthshire and part of East Glamorganshire, the strata immediately underlying the Pennant Sandstones consist of a succession of red and blue shales and marls of greater or less thickness. In the New Tredegar pits, which are not far from this locality, the red and blue ground has a thickness of more than 300 feet. This is, therefore, the kind of ground upon which the landslide is taking place. But as most strata of this kind disintegrate and soften when exposed to air and moisture, it is not improbable that this property of theirs accounts, to some extent at least, for the gradual movement of the deposits lying upon them on the west side of the valley, and that it may be likewise responsible for the more sudden landslide that took place a year or two ago on the opposite side of the valley, which seriously damaged both the Brecon and Merthyr Railway and one of the Powell Duffryn collieries which lay in its path.

My thanks for information concerning the Rhymney Railway and the bridge over it are due to Mr. Cornelius Lundie, formerly general manager, and now consulting director, to the railway company, who has known, and has had occasion to observe, the movements taking place in this locality for the last forty-five years, and is therefore thoroughly conversant with the subject.

W. GALLOWAY.

THE LAW RELATING TO UNDERGROUND WATERS.

IN one of the State papers recently issued by the department of the United States Geological Survey there is a report by Mr. D. W. Johnson dealing with the rights of landowners and others to underground waters, for the purpose of giving the owners of such waters some idea of their rights and obligations.[1]

The report is not intended to be a legal treatise, but as a practical guide for the officers of the hydrological department, showing the relation of the law to problems which are of a more or less hydro-geological character.

The law relating to underground waters in the United States is practically the same as in this country, and the decisions given in the courts there are founded on British precedents modified in some cases by the different circumstances of the two countries.

Underground water is held to comprise all water which for the time being is below the surface of the ground, whether by penetration of the rainfall or soakage from rivers and lakes, and which is dissipated throughout the mass of porous soil or rock, except in cases where the underground water can be traced as moving in a well ascertained and definite course that can be located.

The fundamental principle upon which the laws regulating the use of underground water is formed is this:—That such percolating subterranean waters are a part of the land itself. The land belongs to the owner, whether it be rock, porous ground, earthy matter, or part soil and part water, the water being as much his property as rock, ores, or minerals. Consequently, he may take and use such waters as he pleases, even though such use may damage his neighbour by removing or diminishing water from adjacent wells or springs, by causing subsidence to land or buildings by abstraction of the water, or by rendering the water useless by pollution from sewage or refuse from factories or mines, &c.

This principle has been admitted in the decisions given by the courts owing to the difficulty of proving how much of such water was within the limits of any given area, how much comes from adjacent land, or how much passes from one man's land to that of his neighbour, and the impossibility of predicting what result may ensue from interference with what has been regarded as an unknown quantity. There are, of course, local circumstances or conditions which modify this general statement, but, broadly, this is how the law stands at present.

In the United States, however, conditions have for some time past been undergoing an alteration, and the investigations and observations undertaken by the hydrological department of the Government have been throwing considerable light on the action of underground waters. In many cases the original lack of knowledge which was the reason for the ruling of the law as it now stands has already disappeared.

We recently gave a short illustrated description of the methods adopted by surveyors of the department for measuring and defining the rate and direction of the flow, and more particularly for showing the effect of percolation of deleterious matter from factories, oil wells, &c., on the underground supply of drinking water (NATURE, December 21, 1905).

[1] "Relation of the Law to Underground Waters." By D. W. Johnson. Water Supply and Irrigation Papers, No. 122. (Washington: Government Publishing Office, 1905.)

The state of knowledge regarding the properties of underground water may be said now to have become in advance of the ruling of the courts on some of the questions involved. The earlier legal decisions were made when little or nothing was known regarding the action of the water beneath the surface. Since then the progress of hydro-geological science has established as facts many things regarding underground waters previously unknown or only speculative, and the knowledge of the working of underground waters remains much less in the realms of the "secret, occult, and concealed." It has now become possible to define certain rights in these waters and to protect these rights equally as well as those in surface waters.

A case recently dealt with in one of the American State courts directs attention to the importance of emphasising the influence that the ever-increasing knowledge concerning underground waters may have in governing legal decisions. In an action brought in the State of Pennsylvania regarding the pollution of underground water, the judge remarked:—Geology has become a progressive and in many respects a practical science. More deep wells have been sunk in one State of America than had previously been dug in the entire earth in all time; and that which was formerly held to be unknown and merely speculative regarding the properties of underground water has been by experience reduced almost to a certainty. If it can be shown that the work done by the owner of the land would cause the inflow of salt water or oil to mingle with fresh water, and the means of preventing the mixing are available at a reasonable expense, then clearly it is a violation of the spirit of the law not to recognise the change, and to apply the settled principles of right to the altered conditions of fact.

In another case tried in California it was held that the usual rule of common law on the subject of percolation was not to be held as applying to an arid district that depended entirely for its cultivation on water derived from underground sources, and where the conditions were totally different from those existing in the locality where the rule in question was first established, and therefore an owner has no right to injure his neighbour's land by any unreasonable diversion of underground water by transferring the same for gain to another district.

PHYSICAL RESEARCH IN AMERICA.

TWO volumes, representing the first instalments of what is promised to be an annual publication, have been received from the physical laboratories of Harvard University.[1] Each contains fourteen papers contributed by the professors, staff, and students. In the preface the director, Prof. Trowbridge, acknowledges the great stimulus received by the establishment of the Thomas Jefferson Coolidge research fund, which has provided the laboratory with what the volumes show to be a very fine equipment, and has greatly increased the enthusiasm for physical research.

Most of the papers included are reprints from the *Proceedings of the American Academy* and the *Astrophysical Journal*. It is hardly possible to speak too highly of the handsome treatment they have received at the hands of the printer and binder, and especially of the manner in which the numerous plates have been reproduced. The range of subjects treated is a very wide one, and in a review of this kind it is not possible to deal with each paper individually.

In the first volume Prof. Trowbridge contributes an interesting paper on the spectra of gases and metals at high temperatures. He attempts to apply electrical stimulus of known amount to the gas in a vacuum tube by discharging through it a condenser of known capacity charged to a high potential by his powerful accumulator battery, by which he can obtain pressures up to 40,000 volts. He contrasts the relative intensities of the lines in the spectra thus obtained with the results got by other methods. When theorising on the relative volatility of metals it is desirable, however, to adopt more accurate data than some of those used in this paper, where "soft-iron" is said to melt "not far from 1100°," and aluminium "between 700° and 800°," instead of 657°.

Spectroscopy is evidently a favourite study in the laboratory, since five papers in each of the two volumes are devoted to it. Mr. Lyman gives an explanation of the "ghosts" and "false spectra" sometimes met with when using gratings, particularly in the extreme ultra-violet, and shows in a number of cases the relation between the wave-lengths of the various false lines and those of the parent lines to which they are due.

In another paper he discusses the various kinds of prolongations of spectral lines met with when using gratings, and shows them to be due to a cause quite different from Sir Norman Lockyer's "long and short lines."

Another interesting paper is by Mr. Morse on the spectra from the break in the Wehnelt interrupter, which appears to give spectra of a special character not classifiable under the division of "flame," "arc," "spark," or "enhanced spark."

Mr. B. O. Pierce contributes, in continuation of an earlier research, papers on thermal conductivity of rocks, one of which must have involved a long period of painstaking work. The apparatus employed was on a scale only possible where very considerable funds were available.

Prof. Hall has a paper on a theory of thermoelectric action, and, along with three other workers, one on thermal and electrical effects in "soft iron."

In several instances, work commenced in the laboratory appears to have been dropped on the publication of some paper slightly overlapping the research contemplated. It is a pity, for example, that the fine resistance bridge for platinum thermometry, described by Mr. Edwards, should not be used to solve some of the problems for which it is suited, and that the construction of a gas thermometer should not be proceeded with because of the publication during the past few years of several researches on gas thermometry.

Though none of the papers appear to be of epoch-making importance, the volumes show how a well equipped laboratory may contribute substantially to the advancement of knowledge. It would be interesting to see what effect the endowment of a representative physical laboratory in this country, with funds for research purposes, would have on the character of the work done, especially if at the same time it were possible to arrange that members of the teaching staff should have a more reasonable proportion of their time to devote to research work.

J. A. H.

[1] "Contributions from the Jefferson Physical Laboratory of Harvard University." (Cambridge, Mass., vol. i., 1903; vol. ii., 1904.)

FIREBALL OF JANUARY 27, 1906.

A MAGNIFICENT fireball was seen by many persons in the north of England on the evening of January 27 at 8h. 33m. Descriptions of its appearance have been received from Hull, Bramley, Bradford, Patrington, and other places in Yorkshire, from Sleaford and Billingborough in Lincolnshire, from Cheadle, Staffordshire, &c.

Mr. H. Beckwith, at Hull, observed the meteor travelling horizontally between the "square" of Ursa Major and the Belt of Orion, while at Cheadle, Miss Blagg noted the path as just above ζ Leonis. Mr. R. Felton, at Patrington, estimated the brightness of the object as quite equal to that of the full moon. It left a trail visible for some time afterwards; one observer says it remained for five minutes, two others estimate the duration as eight minutes, while at Billingborough a spectator watched it for more than ten minutes.

The meteor gave a very brilliant flash near its end point, and the suddenness of its apparition startled many people. Several of the observers were enabled to give the position of its flight with fair accuracy from the luminous trail it left behind.

The radiant point appears to have been near θ Boötis, or in $214°+53°$, and the height of the meteor was from about 59 to 45 miles over the North Sea immediately east of the Lincolnshire coast. The disappearance occurred at a point over "the Wash," about 6 miles S.S.E. from Wainfleet. The length of observed path was approximately

42 miles, and probable velocity of the object 24 miles per second.

The radiant point in the right hand of Boötes is very little known as a centre of meteoric divergence in the month of January. The only shower conformable with it was observed at Bristol in 1887–9 January 25–29, 213°+52°.

In recent years fireballs have been very numerous in this month, and especially at the epochs about January 9 to 13 and 24 to 29. They appear, however, to have belonged to a great many different systems, and have not supplied evidence of any rich individual display of bright meteors at this time of the year.

W. F. Denning.

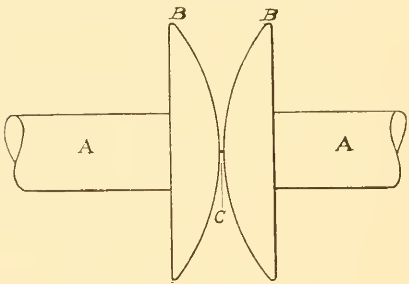
METHOD OF PRODUCING WAVES OF FREQUENCY INTERMEDIATE BETWEEN HEAT WAVES AND HERTZIAN WAVES.

THERE is at present a considerable gap of unexplored wave-lengths intermediate between those of Hertzian waves and what is commonly known as heat. The shortest Hertzian waves which have heretofore been produced are of the order of one millimetre length.

Some years ago the writer discovered a method of producing the heretofore unknown waves above referred to.

It is based on the phenomenon discovered by the writer and published by him in a paper on insulation and conduction read before the American Institute of Electrical Engineers in 1894.

In the accompanying figure, AA are copper rods, BB are plano-convex lenses. The distance between the surfaces of



the lenses depends upon the wave-length which it is desired to produce.

If BB were metallic terminals, the discharge passing at C would have a long wave-length on account of the capacity of BB. It is impossible to make metallic terminals small enough to get very short wave-lengths. But, in the apparatus shown in the sketch, if AA are connected to the terminals of a high-voltage machine sparks will be found to pass at C, and the oscillating conductor is merely the small column of incandescent gas, C.

If the distance between BB is very short, the wave-length will also be very short.

Waves may be produced in this method having a wave-length certainly not longer than a few ten-thousandths of an inch, and there would appear to be no necessary limit to the frequency. It sometimes happens that the discharge tends to pass at a point outside the axis, and hence to give a longer wave-length than desired, but this can be avoided by properly proportioning the curvature of the lenses and the diameter of the rods AA.

Inert gases of the helium type seem to give the best results, but very good results are obtained by using quartz lenses in air, the use of quartz having been suggested to me by Prof. Elihu Thomson. Quartz does not seem to become conducting on being heated by the passage of the discharge to anything like the same extent as glass, and hence the wave-length remains more constant.

Owing to pressure of other work, the writer has been unable to continue these experiments, but the apparatus would seem to be of interest as offering a means of obtaining waves of any desired high frequency.

Reginald A. Fessenden.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—The statement of the income and expenditure of the Common University Fund for 1905, published in last week's *Gazette*, shows that the income was 6806*l*. 9*s*. 8*d*., to which the colleges contributed 6197*l*. 19*s*. 4*d*. under the statute concerning college contributions for university purposes, and the Royal Geographical Society 400*l*. towards the support of the department of geography. The total expenditure was 6260*l*. 14*s*. 11*d*., of which sum 3662*l*. 19*s*. 5*d*. was devoted to scientific purposes, partly in the payment of the salaries of university readers and professors, and partly in assisting various laboratories and providing demonstrators and assistants.

At a meeting of the Junior Scientific Club, held at the Museum on February 23, Mr. M. H. Godby (Christ Church) read a paper on "The Place of Natural Science in Education."

Cambridge.—The Vice-Chancellor has been authorised to convey to Lord Rayleigh the grateful thanks of the University for his magnificent gift of 7733*l*. 12*s*. 8*d*., being the amount of the Nobel prize awarded to him in 1904. Lord Rayleigh desires that 5000*l*. of this should be employed in erecting a new building in connection with the Cavendish Laboratory, and that the remainder should be devoted to the purchase of scientific books and periodicals for the University Library.

Sir George Darwin, K.C.B., Plumian professor of astronomy, will represent the University at the celebration of the 200th anniversary of the birth of Benjamin Franklin at Philadelphia in April.

The Special Board of Biology and Geology recommended that the agreement between the University and Dr. Dohrn, director of the Zoological Station at Naples, be renewed for a further period of five years by the payment to him of 100*l*. per annum out of the Worts travelling bachelors fund.

The General Board of Studies has nominated the following gentlemen as members of the Board of Electors to the professorships named below:—Dr. B. C. A. Windle, to the professorship of human anatomy; Prof. F. W. Oliver, to the professorship of botany; Lord Walsingham, to the professorship of zoology and comparative anatomy; Mr. J. Hutchinson, to the professorship of surgery; the Earl of Carrington, G.C.M.G., to the professorship of agriculture.

The following have been nominated examiners by the General Board of Studies for the special examination in agricultural science and for the diploma in agriculture:—Mr. J. B. Peace, Mr. H. Woods, Mr. T. B. Wood, Mr. R. H. Biffen, Prof. Middleton, Dr. Shore, Mr. T. A. Dickson, and Mr. A. E. Shipley.

At Gonville and Caius College the triennial Thruston prize of 54*l*., open to a member of the college of not more than fifteen years' standing who has published in the course of the preceding three years the best original investigation in physiology, pathology, or practical medicine, has been awarded to Mr. W. S. Perrin, research student of the college. Mr. Perrin is an expert on protozoology, and has published papers on a so-called trypanosome in the oyster and on *Pleistophora periplanetae*.

Lord Rayleigh has promised to lay the foundation-stone of a new science school at Dulwich College on Saturday, March 3.

To the new buildings of the Sorbonne it has been decided to add a new university chemical laboratory, the Institut de Chimie, on a site between la rue Saint-Jacques and la rue d'Ulm, that is, in the neighbourhood of the Sorbonne.

Prof. R. J. Harvey Gibson writes from the Hartley Botanical Laboratories, University of Liverpool, to point

out that the proposed grant referred to in a note last week (p. 406) is to be made to the botanical laboratories to meet the expenses of investigations in applied botany which the agricultural committee of the County Council desires the botanical department of the University to carry out. He adds:—"There is no department of economic botany in the University, nor has any fund been collected for the establishment of such a department, so that the cost of such a school is not in any sense 'guaranteed.'"

THE Treasury has appointed a permanent committee to advise the department as to the distribution of the grant-in-aid of colleges furnishing education of a university standard. The constitution of the committee is as follows:—The Rev. H. G. Woods, chairman, Sir Francis Mowatt, G.C.B., Sir William J. Collins, M.P., Prof. Henry Jackson, and Prof. W. S. McCormick. Mr. R. G. Hawtrey, of the Treasury, will act as secretary. Dr. H. G. Woods, the chairman of the committee, was in 1901 a Treasury Commissioner for the inspection of university colleges. It will be noticed that the interests of science are not represented upon the committee.

THE academic congress, which recently met in St. Petersburg to consider a number of questions relating to Russian higher education, arrived at the following conclusions:—The Imperial Russian universities ought to be State institutions, the duty of which should be to foster the natural sciences; they should be autonomous institutions, responsible only to the Minister of Education; they should, further, be open to persons of both sexes alike, irrespective of nationality and religious creeds; the university diplomas should give no privileges in the entrance to the professions, &c.; the State examinations should be maintained, and those persons desirous of exercising the right of putting their knowledge to professional uses should be required to submit themselves to the corresponding State examinations; the degree of "Master" should be abolished, and those now holding it should receive the "Doctor's" degree.

THE Charity Commission has forwarded to the Education Committee of the London County Council a draft scheme which provides that the City Polytechnic, which hitherto has comprised the Birkbeck College, City of London College, and Northampton Institute, shall cease to exist. It is proposed that the Birkbeck College and the City of London College shall constitute separate foundations, while the Northampton Institute shall constitute a separate charity. The whole of the endowments of the Birkbeck College and the City of London College are determined as educational endowments, and will therefore henceforth be under the control of the Board of Education and not of the Charity Commissioners, but the Northampton Institute, as a charity, will presumably continue to be supervised by the Charity Commission, and power is reserved for the establishment of further schemes in respect of the two colleges by the Board of Education and in respect of the Northampton Institute by the Charity Commission. Subject to these provisions, the several institutions are to be managed in accordance with their existing schemes and by their present governing bodies.

IN the House of Commons on Monday Mr. Austen Chamberlain asked the Chancellor of the Exchequer whether he had undertaken to include in the Estimates for 1906–7 a sum of 20,000*l.* for the building fund of the University College of North Wales, to which fund 61,000*l.* had been subscribed locally; if so, whether any conditions had been attached to the proposed grant; and whether he would make provision in the Estimates for similar grants to the universities and university colleges of England in the same proportion to the local subscriptions. In reply, the Chancellor of the Exchequer said:—"I have undertaken to ask Parliament to make a grant of 20,000*l.* to the building fund of the college when the money is actually required for the scheme, and subject to the condition that a similar sum has first been spent upon it from other sources. No part of this grant will have to be provided in the Estimates for 1906–7. Similar grants have already been made to the two other Welsh colleges of like character. No such grants have in the past been made to university colleges in England, and, as the annual grants to these institutions were largely increased—as I think most properly increased—by the right hon. gentleman when he was Chancellor of the Exchequer, I am not, as at present advised, prepared to recommend a change of policy."

THE annual meeting of University College was held on February 21. Lord Reay, who presided, referred to the incorporation of the college in the University of London, and said its object is to secure the good of university education in London as a whole. Speaking of the proposed college of technology, Lord Reay said he is convinced that increased facilities for higher technological work are required in London, but unless all such higher technological work is in the hands of the same authority there will be the same risk of overlapping, duplication, possibly of triplication, that there has been in the past. Now is the great opportunity for giving to the University its due responsibility, and from what the University has done in the last five years, said Lord Reay, it will not fail to bear that responsibility. If brought within the University the new college of technology would be managed by a college committee much as University College will be managed. Such college committee would be subject to the general direction on matters of university policy of the Senate, but in all other matters it would be practically self-governing. It would be possible to start the new college at once within the University, and while starting it with a committee under the Senate there would be time to consider what modifications in the general constitution of the University would be made necessary.

IN the absence of Mr. Chamberlain, the Chancellor, Alderman C. G. Beale, the Vice-Chancellor, presided at the sixth annual meeting of the Birmingham University Court of Governors on February 21. From the financial statement it was seen that the income for the year had been nearly 43,000*l.*; two new chairs had been inaugurated during the last twelve months, one for electrical engineering and the other for civil engineering. The engineering department as a whole had moved into its new quarters at Bournbrook; although they were expecting the early completion of this section, they were also looking forward to the beginning of another by reason of the generous donation of 50,000*l.* in November of last year; the exact form of the extension was not yet fully decided, but plans for the erection of new chemical and physical departments were being prepared. Remarking upon the difficulty of determining how far a certain sum of money would go in providing such accommodation, Alderman Beale observed that whatever was done should be done on a sufficiently large scale to be permanent; they had sufficient experience to show that the large scale would be the best in the long run. The erection of the Harding Memorial Library, the outcome of the generous gift of 10,000*l.* from the family of the late Mr. Charles Harding, was contemplated. The University had broken new ground, as stated in the principal's report, by the appointment of Mr. W. E. Collinge as special lecturer in economic biology.

LORD HALSBURY delivered an address at the annual prize distribution of the City and Guilds of London Institute on February 16. He said that the old apprenticeship system was a good rough-and-ready way of teaching young people what they wished to practise later in life. What has been attempted more recently, however, is to teach, not only how to do things, but the principles underlying their action. As the result of the developments of modern life, the whole world has become the market for competition. In Germany, France, Switzerland, and other Continental nations it has long been recognised that the old ways in trade and commerce will not do, and the people there have been preparing themselves by technical education, and in other respects, not only to hold their own, but to forge ahead in the industrial race. It is all very well for us to assume an indifferent air, and say that we have been getting on very well. Unfortunately, the facts seem to tell a different story. For the maintenance of our commerce we must use the means that other countries have used with such successful results. As a judge, Lord Halsbury was often struck with the large number of patent cases that

came before him in which the patents had been taken out in Germany and brought over here to be developed and worked at a profit. Why was this? While Germany has founded numerous places for chemical experiment and research, nothing of the kind is provided here, except at such colleges and schools as those belonging to the City and Guilds of London Institute. It is a matter of national concern that whatever is possible should be done to give a stimulus to the scientific and industrial activity of the country.

SOCIETIES AND ACADEMIES.

London.

Society of Chemical Industry (London Section), February 5.—Mr. R. J. Friswell in the chair.—Carburetted water gas in the Bunsen burner: M. **Chikashigé.** Carburetted water gas is now prepared in the Kyoto University by injecting heavy petroleum oil with steam into a water-gas generator filled with ignited coke. The gas produced is passed through a superheater loosely packed with fire-bricks, and then through a scrubber, after which treatment it enters the gas holders. The mean composition of the gas differs little from that of coal gas, and the products of combustion closely resemble those of coal gas. The carburetted gas has no effect on the ordinary laboratory vessels, and the products of combustion, unlike those of plain water gas, are not more injurious in insufficiently ventilated laboratories than those of coal gas.—The loss of nitre in the chamber process, part ii.: J. K. H. **Inglis.** The loss of nitre, which usually amounts to about 3 per cent. of the sulphur burnt, can best be traced by complete analyses of the flue gases. The analysis cannot be carried out by means of aqueous absorbents owing to the formation of complicated bodies by the interaction of nitrous acid and sulphur dioxide. But the analysis may be conveniently made by the fractional distillation of the gases, first at the temperature of liquid air and subsequently at higher temperatures. The results showed that only about 4 per cent. of the lost nitre was lost as nitrous oxide and 43 per cent. as nitrogen peroxide. In the first experiments the temperature of liquid air was insufficient to effect the separation of nitric oxide from the flue gases owing to the vapour pressure of nitric oxide. Some further experiments were therefore made at a lower temperature obtained by making liquid air boil under diminished pressure. The amount of nitrogen oxides found was no greater than in the earlier experiments, and this might therefore mean that nitric oxide is not present in the flue gases.—The removal of nitrous acid from concentrated nitric and sulphuric acid: O. **Silberrad** and B. J. **Smart.** The experiments were made to determine to what extent the reaction between nitrous acid and amines or amides occurs in concentrated acids. Nitric acid containing a small percentage of nitrous acid was taken either alone or in admixture with sulphuric acid. The addition of hydrazine occasions an explosion, and with this exception substances such as urea, lead peroxide, oxamide, methylamine nitrate, and amido guanidine are very inert towards nitrous acid in presence of concentrated nitric acid, although they react readily in dilute solution. The observation of Franchimont that urea nitrate decomposes with evolution of carbon dioxide and nitrous oxide was confirmed.

Zoological Society, February 6.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—Mounted cubs of the timber-wolf (*Canis occidentalis*), obtained in the province of Keewatin, Canada: F. **Gillett.**—Restored models of the skulls and mandibles of Mœritherium and Palæomastodon: Dr. C. W. **Andrews.** The models were prepared by Mr. F. O. Barlow from the original specimens collected from the Upper and Middle Eocene beds of the Fayûm, Egypt, and now preserved in the British Museum and the Geological Museum, Cairo.—Lantern-slides of sections of skin from the palmar and plantar surfaces of twenty-four species of mammals, and the plantar surfaces of seven species of birds: Dr. W. **Kidd.** The functions of the papillary ridges and the papillary layer of the corium in connection with the sense of touch were alluded to.—Histology and physiology of the placenta in the Ungulata: Dr. J. W. **Jenkinson.** A recent examination of the histological structure of the placenta in the sheep and cow has shown (1) that in the formation of the accessory cotyledons of the cow the epithelium lining the cotyledonary crypts arises by simple modification of the uterine epithelium; (2) that in the fully formed principal cotyledons of both cow and sheep there is complete continuity of the intra- with the extra-cotyledonary uterine epithelium; (3) that the greenish-brown pigment so abundantly present in the trophoblast-cells is a derivative of the hæmoglobin of the maternal corpuscles which those cells have ingested. The pigment—which contains no iron—is of two kinds, one of which has a definite absorption spectrum resembling closely that of oxyhæmoglobin. In acid solution the spectrum approaches that of acid hæmatoporphyrin.—A living specimen of a dwarf species of cavy, probably the salt-marsh cavy (*Dolichotis salinicola*): Sir Edmund **Loder,** Bart. Owing to Burmeister (the original describer of the animal) being under the erroneous impression that he had founded the species on young specimens and the fact that two distinct species occurred in the same district, some considerable confusion had been caused as to the status of the different forms of Dolichotis. The author pointed out that the common Patagonian cavy (*D. patagonicus*) differed from the dwarf *D. salinicola* and the larger *D. magellanicus centricola* (the two species found together) in having a broad dark band above the white rump-patch.—A description of Trichorhiza, a new hydroid genus: E. S. **Russell.**—Description of the new genus Melissomorpha, formed for the reception of a horse-fly of the Pangoninæ division of the family Tabanidæ, discovered by Colonel C. T. Bingham in Sikkim: Gertrude **Ricardo.** The insect closely mimicked the Indian bee *Apis dorsata*, L., having the flattened wide tibiæ characteristic of the hive-bee, the general resemblance between the bee and the fly being very striking.—Mammals collected at Kuruman and Molopo in Bechuanaland by Messrs. R. B. Woosnam and R. E. Dent: H. **Schwann.** The specimens, numbering about 120, and belonging to 26 species, were of great interest as being topotypes of several species described by Sir Andrew Smith in his expedition to Kuruman and the interior of South Africa.—Description of a new species of ratel (Mellivora) from Central Africa, also notice of the occurrence of a new subspecies of chevrotain (Dorcatherium) in that district: R. **Lydekker.** The author proposed to divide the genus into three geographical races, viz. the typical form from the Gambia, Bates's chevrotain from the Cameroons, and the present—Cotton's chevrotain—from the Ituri Forest.—The articulation of the vertebrate jaw: H. G. F. **Spurrell.** The object of this paper is to direct attention to the existence of two types of mouth in vertebrates. In one type the articulation is in the plane in which the teeth meet; in the other type it is not in the plane in which the teeth meet, but in mammals above, in reptiles below that level. This alteration in level is attained in mammals by an ascending ramus of the jaw, in reptiles by a long quadrate bone.

Entomological Society, February 7.—Mr. F. Merrifield, president, in the chair.—*Exhibitions.*—Specimen of *Lathrobium laevipenne*, Heer, a beetle new to the British list, taken in a sandpit near Oxted, Surrey, in August, 1905: W. E. **Sharp.**—Specimens of South African butterflies belonging to the Nymphalinæ, Acræinæ, Danainæ, and Papilioninæ: Dr. F. A. **Dixey.** Attention was directed to the significance of the fact that scents of an agreeable nature (as in Pierinæ generally, *Mycalesis safitza*, &c.) were as a rule confined to the male sex, while those of a disagreeable or disgusting character (as in Acræinæ and many Papilios) were often common to both sexes.—Four species of Acræa taken in South Africa during the visit of the British Association: Dr. G. B. **Longstaff.** The species were (1) *A. anemosa*, Hew., from the Victoria Falls, and Mochudi, in Bechuanaland; (2) *A. alboradiata*, Auriv., previously known to Mr. Roland Trimen by two females only, and considered by him as a variety of *anemosa*; (3) *A. atolmis*, Westw., to which Westwood gave the names of *atolmis* and *acontias*, although there seems no doubt they are one species; (4) *A. atergatis*, Westw., the two types of which are in the Hope collection at Oxford.—Two Diptera, which had been observed follow-

ing the bee, *Andrena labialis*, Kirb., by Mr. A. H. Hamm, identified by Mr. G. H. Verrall as a species of Chortophila: Prof. E. B. **Poulton.** Prof. Poulton stated that new and interesting light had been thrown on the observation by Colonel Yerbury, who pointed out that both flies were males. At first sight it seemed astonishing that the bees should be pursued by the males of inquiline flies, but he suggested that the males in this way find their way to the burrows, where they meet the females, which have also reached them in the same manner, or where, more probably, they lie in wait for the freshly emerging females.—Collection of Rhopalocera made in Spain during July and August, 1905: W. G. **Sheldon.** There were also shown for comparison typical European specimens; an aberration of *A. aglaia*, with the black blotches on the superiors enlarged and banded, and with dark suffused ground colour on all wings; and an interesting series of *L. corydon* and var. *hispana*, with forms approaching var. *polonus*, from Aragon, and intermediates between all these forms, and also British, French, and Swiss typical specimens for comparison.—*Papers*.—(1) Some rest attitudes of butterflies; (2) some bionomic points in certain South African Lamellicorns: Dr. G. B. **Longstaff.**—Some new or hitherto unfigured species of South African butterflies: Roland **Trimen.**—Some observations on the reproduction of Hemiptera-Cryptocera by Claydon Hewett: Commander J. J. **Walker.**

Chemical Society, February 15.—Prof. R. Meldola, F.R.S., president, in the chair.—Cuprous formate: A. **Angel.** This salt was prepared by dissolving cuprous oxide in an aqueous ammoniacal solution of ammonium formate under petroleum, diluting with alcohol, acidifying with formic acid, and washing the deposited crystals with ethyl formate. Water immediately hydrolyses it to cuprous oxide and formic acid, and dilute sulphuric acid at once produces a precipitate of metallic copper.—The solubility of triphenylmethane in organic liquids, with which it forms crystalline compounds: H. **Hartley** and N. G. **Thomas.** The results of these experiments confirm the existence of a metastable region in which supersaturated solutions cannot crystallise spontaneously.—The spontaneous crystallisation of supersaturated solutions: H. **Hartley.** It was shown how the difference between metastable and labile solutions might be explained from the kinetic standpoint as a result of the increased solubility of the small crystals which must be first formed in a spontaneous crystallisation.—Preparation and properties of some new tropeines: H. A. D. **Jowett** and A. C. O. **Hann.** The tropeines of methylparaconic, terebic, glycollic, protocatechuic, and phthalidecarboxylic acids were prepared. The results of physiological experiments with these confirm Ladenburg's view that for mydriatic action to exist in a tropeine the acyl group should contain a benzene nucleus and an aliphatic hydroxyl in the side-chain containing the carboxyl group.—Studies in asymmetric synthesis, iv., the application of Grignard's reaction for asymmetric syntheses: A. **McKenzie.** The author has studied the action of magnesium propyl iodide, magnesium *iso*butyl iodide, and magnesium α-naphthyl bromide respectively on *l*-menthyl benzoylformate, and effected in each case an asymmetric synthesis of a substituted *l*-glycollic acid.—*o*-Cyanobenzenesulphonic acid and its derivatives: A. J. **Walker** and E. **Smith.** The authors described a modification of Jesurun's method for the preparation of *o*-cyanobenzenesulphonic chloride, and referred to various substances obtained from this by reduction and hydrolysis.—The condensation of dimethyldihydroresorcinol and of chloroketodimethyltetrahydrobenzene with primary amines, part ii., diamines, *m*- and *p*-phenylenediamines: P. **Haas.**—A modification of the volumetric estimation of free acid in the presence of iron salts: C. Chester **Ahlum.** The iron is precipitated by means of sodium dihydrogen phosphate, and the filtrate titrated with standard sodium hydroxide. In the reaction of the ferric salt with the phosphate, a definite quantity of acid, directly proportional to the amount of "ferric" iron present, is liberated, and is corrected for by estimating the "ferric" iron present before titrating. The method is applicable to natural waters containing iron salts and free acid.—The theory of alkaline development, with notes on the affinities of certain reducing agents: S. E. **Sheppard.**—Resolution of 2:3-dihydro-3-methylindene-2-carboxylic acid into its optically active isomerides: A. **Neville.** The acid forms with *l*-menthylamine a well defined crystalline salt, which on crystallisation from ethyl acetate gives, after a few crystallisations, the pure salts of the *d*-acid and *l*-base.

PARIS.

Academy of Sciences, February 19.—M. H. Poincaré in the chair.—The simultaneous determination of two points by means of graphical construction on the large scale: M. **Hatt.**—The boiling and distillation of nickel, iron, manganese, molybdenum, tungsten, and uranium: Henri **Moissan** (see p. 424).—The function of organic matter in nitrification: A. **Müntz** and E. **Laine.** The experiments of Winogradsky and Omeliansky have given rise to the idea that the presence of humic material is not only unnecessary, but even harmful to the process of nitrification. The present researches deal specially with the *rôle* of humus in the nitrifying process, and it was found that organic material in this form does not hinder the process, and may be favourable. Abundance of humus is not an indispensable condition for nitrification, but its presence is favourable to the multiplication of the organisms, and the nitrification ultimately becomes more rapid.—The reproduction of architectural monuments from their photographs, practised especially in Germany: M. **Laussedat.**—Synthesis of tertiary alcohols derived from paramethylcyclohexane: Paul **Sabatier** and A. **Mailhe.** Methylcyclohexanone (1:4) is readily obtained from paracresol by reduction in presence of reduced nickel. It reacts energetically with organomagnesium halogen compounds, and the product of the reaction treated with water gives tertiary alcohol. The alcohols arising from the action of the methyl, ethyl, propyl, isopropyl, isobutyl, isoamyl, and octyl magnesium iodides (or bromides) are described in detail, and also the substituted ethylenes arising from their dehydration. The reaction with phenyl-magnesium bromide and benzyl-magnesium chloride is also given. The optical constants were determined, and found to correspond very closely with the molecular refractive powers calculated from the coefficients of Conrady and Brühl, thus furnishing a further proof that the hexamethylene ring introduces no abnormality into the refractive constant.—The dangers of the ingestion of dead tubercle bacilli into tuberculous and healthy animals: A. **Calmette** and M. **Breton.** In the experiments described the tuberculous bacilli were sterilised by heating to 100° C. Tuberculous guinea-pigs had their death hastened by the repeated injection or ingestion of sterilised tubercle bacilli, the general effect being similar to that produced by repeated injection of tuberculin. In healthy animals the results are injurious, sometimes producing disorders resembling those produced by tuberculin. One practical conclusion to be drawn from this work is that milk from tuberculous cows, even after sterilisation by heat, is not a safe food, especially if the person taking such milk is already tuberculous.—The photographic study of the duration of discharge in a Crookes' tube: André **Broca** and M. **Turchini.** The photographs of the spark were taken from a rotating mirror, the velocity being adjusted so that a time of 0·001 second corresponded to 63 mm. on the plate. The photographs showed a sudden commencement of the discharge lasting 0·00025 second, followed by a weakening terminating asymptotically at the end of about 0·0008 second. With a soft tube the same form of discharge was observed, but the time throughout was greater. The authors regard this method as giving an upper limit for the time of discharge.—A method for measuring the total quantity of X-rays emitted in a given time: M. **Gaiffe.**—The radio-activity of springs of potable water: F. **Diénert** and E. **Bouquet.** Measurements are given of the radio-activity of the water from the Group de Nouvet, Erigny, Rivière, and Breuil springs.—The condensation of the acetylenic nitriles with phenols. A general method of synthesis of β-substituted acrylic β-oxyphenol nitriles: Ch. **Moureu** and I. **Lazennec.** It has been found that the condensation between alcohols and nitriles of the type R—C≡C—CN also takes place when phenols are substituted for the alcohols. Details are given of seven compounds formed in this way.—Researches in the pyrane series: E. E. **Blaise** and H. **Gault.**—The presence of

formaldehyde in caramelised substances: A. **Trillat.** Quantities of formaldehyde varying from traces up to 0·27 per cent. have been found in caramel; the higher the temperature at which the caramel is formed, the higher the percentage of formaldehyde. This fact may account for the observed variation in fermentation of slightly burnt sugar.—The bryological vegetation of the Antarctic regions: Jules **Cardot.** An account of forty-six mosses collected in various Antarctic expeditions.—The sporulated yeasts of Glœosporium: P. **Viala** and P. **Pacottet.**—The influence of grafting on the quality of the grape and wine, and its use in the systematic improvement of sexual hybrids: M. **Curtel** and A. **Jurie.** The evolution of colonies of *Diplosoma spongiforme* and the "displanchtomy" of the ascidiozoids: Antoine **Pizon.**—The male and the sucker of *Nicothoa Astaci*: A. **Quidor.**—The peat deposits of the sea shores of Brittany, to the north of Morlaix, Finistère: L. **Cayeux.**—A whirlwind of very small dimensions: M. **Luizet.**

CALCUTTA.

Asiatic Society of Bengal, January 10.—Types of fever in Calcutta: Major L. **Rogers.**—Description of two new species of cyprinoid fishes from the Helmand basin: C. Tate **Regan.** Five species of fish were taken in the stream of the Helmand basin by the members of the recent Seistan Arbitration Commission. Of these, two, *Scaphiodon macmahoni* and *Nemachilus rhadinaeus*, are described as new.—The origin of mankind (according to the Lamaic mythology): Rai Sarat Chandra Das Bahadur. In the beginning of the *Kalpa*, when living beings had sprung up in the regions of the Rirab (*Sumeru*) mountain, situated above the residence of the four *Dika Pala* (guardians of the world called *Maharaja Kayiko*), two Devaputra (angels) came down to this earth from Heaven, being miraculously transformed into human shape. One of them was *Nima* Rabnang, and the other was *Dawa* Dimeh. These were followed by other angels, whose term of residence in Heaven had expired at the exhaustion of the merit they had acquired before. Thus humanity evolving from heavenly origin in course of time multiplied on earth.—Persian folk songs: Major D. C. **Phillott.**

DIARY OF SOCIETIES.

THURSDAY, MARCH 1.

ROYAL SOCIETY, at 4.30.—An Experimental Inquiry into the Factors which determine the Growth and Activity of the Mammary Glands: Miss J. E. Lane-Claypon and Prof. E. H. Starling, F.R.S.—The Specificity of the Opsonic Substances in the Blood Serum: Dr. W. Bulloch and G. T. Western.—The Internal Anatomy of Somoxys: Lieut. F. Tulloch, R.A.M.C.

CHEMICAL SOCIETY, at 8.30.—Studies of Dynamic Isomerism. Part IV. Stereoisomeric Halogen Derivatives of Camphor: T. M. Lowry.

ROYAL INSTITUTION, at 5.—The Physiology of Plants: F. Darwin, F.R.S.

LINNEAN SOCIETY, at 8.—On a New Type of Stem from the Coal-measures: Dr. D. H. Scott, F.R.S.—Notes on Some Species of Nereis in the District of the Thames Estuary: Dr. H. C. Sorby, F.R.S.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Coast Lines Protected by Chain Cable Groynes: R. G. Allanson-Winn.

GEOLOGISTS' ASSOCIATION, at 8.—Note on an Ostracodal Limestone from Durlston Bay, Dorset: F. Chapman.—(1) Remarks on the Upper Chalk of Surrey: (2) The Devonian Limestones of Lummaton Hill, near Torquay: A. J. Jukes-Browne.

FRIDAY, MARCH 2.

ROYAL INSTITUTION, at 9.—Hippocrates and the Newly Discovered Health Temple at Cos: Dr. R. Caton.

SATURDAY, MARCH 3.

ROYAL INSTITUTION, at 3.—The Corpuscular Theory of Matter: Prof. J. J. Thomson, F.R.S.

MONDAY, MARCH 5.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Ignition of Nitro-compound Explosives in Small Arm Cartridges: W. D. Borland.

VICTORIA INSTITUTE, at 4.30.—On the Bearing of Recent Oriental Discovery on Old Testament History: Rev. A. C. Robinson.

TUESDAY, MARCH 6.

ROYAL INSTITUTION, at 5.—Food and Nutrition: Prof. W. Stirling.

SOCIETY OF ARTS, at 8.—Imperial Questions in the West Indies: Sir Nevile Lubbock, K.C.M.G.

ZOOLOGICAL SOCIETY, at 8.30.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Continued Discussion*: A Plea for Better Country Roads: G. R. Jebb.—Country Roads for Modern Traffic: J. E. Blackwall.—*Probable Paper*: The Widnes and Runcorn Transporter-Bridge: J. J. Webster.

WEDNESDAY, MARCH 7.

SOCIETY OF ARTS, at 8.—Art in Painting and Photography: J. C. Dollman.

ENTOMOLOGICAL SOCIETY, at 8.—The late Prof. Packard's Paper on the Origin of Markings of Organisms: H. Eltringham.

GEOLOGICAL SOCIETY, at 8.—On the Occurrence of Limestone of the Lower Carboniferous Series in the Cannock Chase Portion of the South Staffordshire Coalfield: G. M. Cockin.—Liassic Dentaliidæ: L. Richardson.

SOCIETY OF PUBLIC ANALYSTS, at 8.

THURSDAY, MARCH 8.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: The Microscopic Changes in the Nervous System in a Case of Chronic Dourine or "Mal de Coït," and Comparison of the Same with Those found in Sleeping Sickness: Dr. F. W. Mott, F.R.S.—On the Relationship between Hæmolysis and Phagocytosis of Red Blood Cells: Dr. R. D. Keith.

A REVISED DOCTRINE OF VALENCY.

Neuere Anschauungen auf dem Gebiete der anorganischen Chemie. By Prof. A. Werner. Pp. xii + 189. (Brunswick: F. Vieweg and Sohn, 1905.) Price 5 marks.

IN 1893 Prof. Werner published his first important paper on the constitution of inorganic compounds, and expounded a new theory for the classification of the large and complex group of substances known as metal-ammonia compounds. Of these compounds a few are common enough, such as the deep blue substance formed by the addition of ammonia to solutions of copper salts, but the greater number do not come within the range of ordinary analytical chemistry; they are for the most part of no industrial importance, and consequently they are scarcely heeded except by a very limited number of chemical workers. The class of cobaltamines which has vexed many a generation of chemical students does not measure the limits of complexity to which these compounds extend, and certainly, without the guiding light of some good theory as to their structure, the metal-ammonia group constitutes one of the most bewildering tracts of inorganic chemistry.

It is therefore a real service that Prof. Werner renders in publishing in this volume (No. 8 of a series of monographs on natural and mathematical science, collectively called "Die Wissenschaft") a full exposition of his theory and an *aperçu* of the compounds to which it specially applies. We must not give the impression, however, that Werner's theory applies only to metal-ammonia compounds. It is a general theory ranging over chemistry as a whole, and is applied to so simple a substance as sulphuric acid. To describe it in a few words is almost impossible. Perhaps the most central thing is the substitution of the idea of association (Anlagerung) for the strict and definite linkage implied in the ordinary valency theory. This idea has, in a vague way, long prevailed in chemistry in the distinction drawn between atomic and molecular compounds. In $CuSO_4$ we are accustomed to represent definite atomic linkages according to the definite valencies of the component atoms. How are we to represent the attachment of $5H_2O$ to $CuSO_4$ in the hydrated salt? The idea that valency is not a sharply fixed quantity, and that it is not necessarily exhausted when a stable compound is formed, is familiar to us in the hypothesis of residual affinity.

Prof. Werner would have us revise our somewhat diagrammatic and artificial ideas of valency. We are to think of an atom as a small material sphere, from the centre of which the attractive force of affinity is exerted uniformly in every direction. Segregation of the affinity into units of valency is not to be supposed; valency is merely to mean the observed proportional numbers in which atoms associate with one another. It is not dependent on one atom alone, but on the nature of all the atoms that form the molecule. The proportion of the affinity which is spent between two atoms is confined to the restricted circular surface of contact [theoretically one would say a point], the *Bindefläche,* and depends in a high degree on the nature of the atoms. Thus, the author adds, we obtain a rational picture to represent the varying valency of an atom, whilst from the dependence of the distribution of the surfaces of contact on the relative magnitudes of the atoms we reach, without further hypothesis, a space configuration of the molecule.

As the simplest possible illustration of the advantage claimed for these views we may cite the formation of sulphuric acid by the union of SO_3 and H_2O. In each of these molecules it is usually considered that the valencies of the atoms are satisfied. That being so, the readiness of the two molecules to unite must be attributed to some selective action. This is found in the tendency for the group (OH) to be formed, and hence we write $SO_3 + H_2O = O_2S(OH)_2$. According to Prof. Werner, on the other hand, we must suppose that neither the sulphur in SO_3 nor the oxygen in H_2O has spent its affinity, and that accordingly the combination of the two molecules is to be represented as follows: $O_3S + OH_2 = O_3S.OH_2$. At the same time he admits that the compound may pass into the configuration $O_2S(OH)_2$. It might seem, then, that there is not much gained. But he claims that the great merit of this view lies in its conformity with that which must be taken of analogous combinations where a secondary arrangement does not take place. Such a case is to be found in the union of halides to form what are, though commonly called double salts, compounds strictly of the same order as oxysalts. Thus we have $KCl + AuCl_3 = KAuCl_4$ analogous to $K_2O + SO_3 = K_2SO_4$. $KAuCl_4$ is as much a potassium salt as K_2SO_4, and, though it may not be impossible to give an ordinary valency formula to some of these compounds, their formation cannot be explained by anything corresponding to the supposed primary cause (the formation of KO groups) in the union of K_2O and SO_3. The attempt to bring double halides as a whole within the ordinary valency doctrine has not been successful.

But, as stated above, Prof. Werner's theory has arisen in connection with the metal-ammonia compounds, and we will conclude this notice with a slight indication of its application there. In the metal-ammonia compounds we have an electropositive atom, a number of (NH_3) groups, and electronegative atoms or groups. It is supposed that the positive atom has the power of associating itself with or *coordinating* a certain number of atoms or groups which must be supposed to be in contact with this central atom and to constitute a sort of first layer. The whole group also forms the positive ion. Beyond and outside this we have negative atoms or groups which give the negative ions.

Luteo-cobalt chloride has the composition

$$CoCl_3 6NH_3.$$

Cobalt is here shown with the valency of a triad, and as a matter of fact the whole of the halogen may be precipitated by silver nitrate. Purpureo-cobalt chloride

is $CoCl_3.5NH_3$, but only two-thirds of its chlorine can be precipitated. In praseo-cobalt chloride, $CoCl_3.4NH_3$, only one-third of the chlorine reacts as an ion, whilst the compound $CoCl_3.3NH_3$ is not ionised at all.

Now, according to Prof. Werner, the coordination number of cobalt in all these compounds is six, that is to say, the cobalt atom is in all cases associated with six groups or atoms. Outside this are the negative ions. The valency of the positive ion diminishes as the electronegative element in it is increased. Thus we have the following series of compounds:—

$$[Co(NH_3)_6]'''Cl_3;\ [Co(NH_3)_5Cl]''Cl_2;\ [Co(NH_3)_4Cl_2]'Cl;\ \text{and } [Co(NH_3)_3Cl_3]^\circ.$$

It will be seen that here again the essence of the theory lies in the idea of coordination or association as distinct from ordinary valency with its separate linkages. The same ideas may be extended to water of crystallisation in hydrated salts.

This slight sketch will, it is feared, give but a poor idea of the ingenuity and comprehensiveness of Prof. Werner's theory, but it is all that the limits of space allow. The book before us may be strongly commended to all who are interested in the development of chemical theory, and though, no doubt, the new doctrine cannot by any means be called unexceptionable, there is much in Prof. Werner's book that is interesting and stimulating quite apart from the clear exposition of the particular views it is intended to disseminate.

A. SMITHELLS.

THE DANISH FISHERY INVESTIGATIONS.

Meddelelser fra Kommissionen fra Havundersøgelsen. Serie Hydrografi, Bd. i., Nos. 7–8; *Serie Fiskeri*, Bd. i., Nos. 4–8; *Serie Plankton*, Bd. i., No. 3. (København, I Kommission Hos C. A. Reitzel, 1905.)

THE reports issued by the Danish section of the International Fisheries Investigation Organisation deal to a greater extent with purely biological matters than do the publications of the corresponding British committee. Thus of the present instalment of reports two relate to hydrographical researches, one to plankton studies, while five deal with the life-histories of species of fishes of economic importance.

The hydrographic reports consist of an investigation by Mr. J. P. Jacobsen on the solubility of oxygen in sea-water, with a description of the methods and apparatus employed. Mr. J. N. Nielsen also contributes an account of several hydrographic cruises made by the *Thor* in the summer of 1904 on the north coast of Iceland, and a discussion of the results obtained. The sea-water on the north coast of Iceland is derived from warm Atlantic water in the Denmark Strait the Irminger current—and from much colder, but lighter, water of Arctic origin, which comes from the East Greenlandic polar current. The climate of the North Icelandic coast is dependent to some extent on the relative distribution of these two contributing currents. The Irminger current flows north along the west coast of Iceland, and then, as a result of the earth's rotation, along the north coast. This latter cause, and also the interference of the East Greenlandic polar stream, produce a further rotation of the current, so that it may even round the north-east coast of Iceland and flow south. Along its whole course the Irminger current yields up heat to the atmosphere, cooling by convection as it does so, so that even the lower layers give up their heat. Land-water, produced by the melting of ice and snow masses, cools down the coastal waters, and, being of lower salinity, causes a surface current seawards during the summer and an undercurrent landwards. In winter the lower temperature of the land cools the sea-water, which then sinking in consequence of its greater density, flows seawards as an undercurrent, while it is replaced by a surface current moving towards the land.

The distribution of the comparatively warm Irminger current is affected by the presence of drift ice; in those years when drift ice is abundant on the Icelandic coasts, the cold (though less dense) Arctic water spreads over the surface, and blocks to a variable extent the eastward passage of the Atlantic water. But it also prevents the conduction of heat from the latter to the atmosphere, and as a result, during these hard ice years, the mean temperature of the air of the first six months of the year is much lower than in those years when drift ice is absent or less abundant during the months in question. In this connection the suggestion that telegraphic cable communication with Iceland, and a coast telegraph line, should be established is of considerable interest, for the advent of the ice can usually be foretold by observations of the temperature of the sea.

Not only does the temperature of North Iceland during the winter depend on the distribution of the eastern branch of the Irminger current, but the fisheries vary in an analogous manner. This appears to be the case with the great herring fishery, and cod appear also to travel to the west, north, and east of Iceland with the current, not appearing in abundance until the temperature of the water reaches a certain value. The pelagic larvæ of the latter fish are also distributed by the current, as well as by the offshore and inshore movements of the water due to the cause mentioned.

A short note by Mr. C. G. J. Petersen on the occurrence of Leptocephali is of exceptional interest. It is well known that finds of this stage of the common eel have been very rare in northern waters. Dr. Petersen tells us that it occurred to him to look for these larvæ in warm and deep Atlantic water, using special fishing apparatus. Accordingly in May, 1904, Dr. J. Schmidt found a typical Leptocephalus at a station south-west of the Færöe Isles, in water more than 1000 metres in depth, and in a postscript it is also added that great quantities of *Leptocephalus brevirostris* have been found by Schmidt "in the depths of the Atlantic," presumably near the same place. Dr. Petersen concludes that it is here, not in the Baltic or North Seas, that the eels of Northern Europe breed, passing in their migrations either the North Sea or

the English Channel; and he discusses the value of this discovery from the point of view of the Swedish, Danish, and German eel-fisheries. We await with considerable interest the further account of these remarkable investigations.

The other reports are also of considerable interest. Mr. A. C. Johansen writes on the life-history of the young post-larval eel. Mr. A. S. Jensen contributes a paper on the occurrence of the otoliths of Gadoid fishes in the bottom deposits of the polar seas between the Færöes, Jan Mayen, and Scotland. Samples of mud obtained from the sea-bottom in these regions frequently contained otoliths derived from various Gadus species. Nevertheless, the trawling operations of the *Michael Sars* showed that the cod does not live at the bottom of these seas. The occurrence of Gadus otoliths is therefore to be explained by the horizontal migration of these fishes from the shore grounds near the surface of the sea. Some observations made by Mr. T. Scott on the occurrence of whiting otoliths in the stomach of the porpoise show also that these structures may be distributed over wide areas of sea-bottom, since whiting are eaten in large numbers by the porpoise and the otoliths may be evacuated in an undecomposed condition. This is presumably the case also with other of the smaller gadoid fishes.

The remaining papers include a study of the post-larval stages of Gadus, spp., and of *Brosmius brosme* by Mr. J. Schmidt, both notable additions to the literature of the subject, and a description of several new Peridinians by Mr. O. Paulsen.

JAS. JOHNSTONE.

THE EVOLUTION OF BIOLOGY.

Geschichte der biologischen Theorien, seit dem Ende des siebzehnten Jahrhunderts. Teil i. By Dr. Em. Radl. Pp. vii+320. (Leipzig: W. Engelmann, 1905.) Price 7s. net.

ALTHOUGH biology is now permeated by the evolution idea, and has continually before it the ideal of giving a genetic description of the present phase of the animate world, there is some reason to fear, as Dr. Radl indicates, a growing apathy towards the study of the evolution of the science itself. Whether it be that many workers share Nietzshe's view that the study of history paralyses the intelligence, or that they feel it their primary business to make history, not to read it, or that they regard historical inquiries as the philosopher's task, not theirs, it seems certain that too little attention—in our investigations, theories, and teaching alike—is paid to the historical evolution of the science. A notorious example may be found in the biological work of Herbert Spencer, who, though he had almost accidentally found inspiration from a slight acquaintance with the work of von Baer, deliberately set his face against looking for more. He preferred to think for himself. But all cannot be excused as we excuse Spencer, and even his work suffered from his peculiarly detached independence of outlook. Whether we will or no, the past lives in the present, and he who thinks himself most emancipated from all scientific tradition may be a signal instance of the rehabilitation or recrudescence of doctrines which characterised his unknown intellectual ancestors. It is not as if scientific discoveries were successive special creations which had their day and ceased to be, giving place to others unaffiliated to them. On the contrary, as Dr. Radl's book, and any other piece of careful historical work, shows, biology is an evolution. Generalisations grow and vary, there is an amphimixis of ideas, there is an adaptation to the social environment, there is a struggle for existence and a survival of the fittest.

Without much discussion of the factors which brought about the scientific renaissance, Dr. Radl begins by showing how the influence of Aristotle persisted in men like Cæsalpinus, Harvey, Glisson, and Redi. The second chapter shows how the mechanical modes of interpretation, vindicated by the physicists, began to insinuate themselves into biology, through Descartes, Borelli, Fr. Hoffmann, and Dr. Willis. The advent of the microscope is then discussed, and an interesting account is given of the work and influence of Malpighi and Swammerdam. A reaction from Cartesian mechanism found expression through the genius of Leibnitz, and vitalism its first thoroughgoing exponent in Stahl.

The fifth chapter deals with the first half of the eighteenth century, with the successors of Malpighi and Swammerdam, and with the early preformationists, such as Bonnet, Haller and Buffon. Then follows an account of Linné's systematic work. Wolff is the central figure of the next chapter, which deals with the foundation of the epigenetic theory. Gradually the conception of individual development expanded into that of racial evolution, but even more in the minds of philosophic thinkers than of naturalists. The ninth chapter gives us the history of the rise and progress of morphology, illustrated especially with reference to Cuvier and Étienne Geoffroy St. Hilaire, Jussieu and P. De Candolle. After a brief chapter on Bichat as representative of vitalism at the end of the eighteenth century, the author passes to a more detailed study of the German "Naturphilosophie," as illustrated by Herder, Kant, Fichte, and Schelling among philosophers, by Kielmeyer, Goethe, Oken, Blumenbach, and Treviranus among biologists. The present volume merely begins the story of the evolution of evolution theory, the two last chapters being devoted to Erasmus Darwin and Lamarck.

Having indicated the scope of this valuable historical treatise, we must now express our high appreciation of the author's workmanship. He shows a first-hand acquaintance with the works with which he deals, and yet he has not allowed himself to be overwhelmed by his scholarship. He has a keen selective instinct and a rare terseness, and although he has written in what was to him a foreign language, his style is lucid and often vivid. One cannot but be impressed in reading the interesting history with Dr. Radl's calmness and independence of judgment; he is neither depreciative of men like Oken nor eulogistic of men like Lamarck; he states their case with justice, and gives chapter and verse for his judgments. In some cases,

e.g. that of Lamarck, his estimate is by no means that which many authoritative writers have expressed.

As we lay aside the volume some general reflections remain convincingly with us—that the history of biology is a rational evolution, and at the same time inextricably intertwined with social evolution; that the same general ideas are re-incarnated century after century in more evolved forms; that each generation meets the same old difficulties on a higher turn of the spiral; that clearly thought-out conceptions which seem for a time to be vanquished re-assert themselves with renewed vigour, and find their nosition in a more complete synthesis. The modern biologist, intent on new discoveries, has no use for Aristotle, Descartes, and Leibnitz, but their influence may be upon him none the less. In speaking of the aqueduct of Sylvius, the Malpighian tubules, the Graafian follicle, or the Cuvierian organs, we quaintly acknowledge our debt to the past, but perhaps we betray our indebtedness more when we are least conscious of it, for even the most modern system of biology is, like our own body, a veritable museum of relics. J. A. T.

STOMATA AND PHYLOGENY.

Der Spaltöffnungsapparat im Lichte der Phylogenie. Ein Beitrag zur "phylogenetischen Pflanzenhistologie." By Dr. Otto Porsch. Pp. xiv+196. (Jena: Gustav Fischer, 1905.) Price 8 marks.

THIS work, as its title announces, is an attempt to use the stoma as a mark of relationship, and thus to make it serve as a guide to the phylogeny of plants. The author is filled with a pleasant enthusiasm for his subject, and this he contrives to convey to his readers, who, whether or no they are in complete agreement with his views, will not deny that he has produced an interesting and suggestive book. Personally, we think he has done more, and that his work has decided value. He begins by showing (what has to some extent been shown before) that definite types of stoma run through certain classes or natural orders. He makes it clear that these types remain recognisable even in plants exposed to various environments. The gymnospermous type, for instance, occurs in plants of such diverse habit as Bowenia, Gingko, Dioon, and Gnetum.

The author allows that the gymnosperm type is essentially a stoma adapted to xerophytic conditions. This brings us face to face with what is a difficulty in inquiries of this sort—namely, how far persistence of type is due to adaptation. This is especially difficult in regard to the xerophytic habit, because our knowledge of the conditions which make this habit of value is recent, and probably incomplete. It is only comparatively lately that conditions of life in a salt-marsh, an English heath, and in the alpine regions of the tropics have been recognised as equivalent environments in regard to transpiration. The author is, however, fully aware of the difficulty in question.

It is interesting to find the gymnospermous stoma occurring in Casuarina, a genus known to possess morphological characters which have suggested that it may be an offshoot from an ancestor common to gymnosperms and angiosperms. In concluding this section the author has some remarks on the minuter taxonomic value of the stoma, *e.g.* in Dasylirion, where the stomatal characteristics may be used to distinguish the species. He also directs attention to the Commelinaceæ and Eriocaulaceæ, and to the genus Eucalyptus, in all of which the stoma is characteristic. As showing the possible value of the stoma to the palæobotanist he quotes the case of a fossil Potamogeton recently shown by its stomatal type to belong to the Loranthaceæ. Porsch gives an interesting account of reduced and rudimentary stomata in the true leaves of Ruscus, in parasites, and in submerged plants. The latter case is especially interesting because here the stomata can hardly be of use for gaseous exchange. But in the petals of flowers or the bulky stems of holoparasites it is clear that they may be of importance for respiration. This is a function of the stoma which Porsch does not sufficiently discuss; thus in referring to the stomata of petals he considers transpiration alone. The fact that large petals occur devoid of stomata while others (Galtonia) have perfect ones shows that the question is in need of physiological inquiry.

In another interesting section the author describes the stomata of seedling leaves, which are generally of an undifferentiated type, even when the adult leaves have highly specialised stomata, *e.g.* in Hakea, *Spartium junceum*, &c. This seems at first sight a case of "recapitulation," but the author is careful to supply an alternative view, viz. that in the early stages of existence a plant is less subject to drought, so that the simple stomata of the seedling may be an adaptation to conditions less rigorous than those to which the adult is exposed. The author, however, accepts, with certain reservations, the recapitulation point of view.

The last section of the book deals with stomata in relation to alternate generation. Porsch holds (with Wettstein) the sporophyte to be an adaptation to life on dry land in contrast to the gametophyte, which retains aquatic characters. Taking the Bryophytes as the lowest class in which stomata occur, he again follows Wettstein in placing the mosses in the lower division, the liverworts being a more specialised form. It is in harmony with this view that in the mosses stomata should occur only in the sporophyte. Among the normal two-celled stomata are occasionally found others of the four-celled type. This he looks on as a "reminiscence" of an earlier form, in which the intercellular spaces open externally in the simplest manner between four epidermic cells.

In the liverworts, on the other hand, the gametophyte possesses openings which function as stomata. There is only one group in the liverworts which exhibits a highly organised sporophyte, and here in Anthoceros we find true stomata having a pair of guard cells, which are probably of a higher type than occurs elsewhere among the Bryophytes.

Among the Pteridophytes the most interesting fact is that the stomata are of a type that may be supposed to be the forerunner of the gymnospermous stoma. The characteristic lignification is not always present

but in some cases, *e.g.* in Todea, we find lignification almost identical with that of certain gymnosperms.

On the whole the author may be congratulated on having attained the end which he had in view, namely, by tracing the history of a definite organ through the vegetable kingdom, to demonstrate the fruitfulness of the phylogenic method. F. D.

OUR BOOK SHELF.

Economic Geology of the United States. By Heinrich Ries. Pp. xxi+435. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1905.) Price 2.60 dollars net.

THIS volume embodies the elementary course of economic geology at Cornell University, where the author is assistant professor. Some knowledge of geology and mineralogy on the part of the student is presupposed, and the work deals exclusively with North American mineral deposits. At the same time North America is so preeminently the continent of mineral deposits, nearly all types and forms being represented within its vast mineral areas, that a treatise on American economic geology is nearly the same thing as a study of mineral deposits in general.

The mode of arrangement differs from that of other books on the same subject in that predominance is given to the non-metallic minerals, the value of the production of which exceeded that of the metallic minerals in 1903 by thirty million pounds. The twenty chapters into which the book is divided deal respectively with (1) coal; (2) petroleum, natural gas, and other hydrocarbons; (3) building stones; (4) clay; (5) lime and calcareous cement; (6) salts; (7) gypsum; (8) fertilisers; (9) abrasives; (10) minor non-metallic minerals; (11) mineral waters; (12) soils and road materials; (13) ore deposits; (14) iron; (15) copper; (16) lead and zinc; (17) gold and silver; (18) silver lead; (19) aluminium, manganese, and mercury; and (20) minor metals.

In each chapter the treatment is the same. An account of the minerals is followed by particulars of their distribution in the United States, with sketch maps, details of their use, recent statistics of their production in the United States and in the world, and a carefully selected bibliography. The twenty-five plates reproducing photographic views of mines and the ninety-seven diagrams in the text are alike excellent. Altogether the work is an admirable one, and we strongly commend it to teachers in this country as a source of concise, accurate, and recent information regarding the mineral deposits of the United States.

Botanische Jahrbücher. Edited by Dr. A. Engler. Vols. xxxiii., xxxiv., and xxxv. Parts i.–iii., with index vols. i. to xxx. (Leipzig: W. Engelmann, 1902–5.)

THE series of papers produced under the direction of Dr. Engler, as the "Beiträge zur Flora von Afrika," continues to engage the attention of workers at the botanic museum in Berlin. The papers that give merely descriptions of new species are chiefly serviceable to monographers, but the results become more interesting when they are collated for a genus or an order, as in the revision of the Ochnaceæ by Dr. Gilg. In a short article that will be found in *Beiblatt,* No. 79, Dr. Engler summarises the general progress of the study of African botany in Berlin, and indicates where further collections and explorations are required. He refers to Dr. Fülleborn's collections of the lower algæ and Bacillariales taken from Lake Nyassa. They have been examined by Dr. Schmidle and Dr. Otto Müller, and their descriptions and deductions are published in these volumes. Other systematic compilations include a contribution to the flora of Madeira and the Canary Islands by Mr. J. Bornmüller, some notes by Drs. Gilg and Loesener on the flora of Kiao-chau, the Chinese territory that was occupied by Germany in 1898, and the "Fragmenta Phytographiæ Australis occidentalis," written by Drs. Diels and Pritzel. Among the cryptogamic contributions, Mr. G. Hieronymus publishes an account of the pteridophytes collected in Ecuador and Colombia by Mr. H. C. Lehmann, German Consul, and Mr. E. Lemmermann deals with the algal vegetation in the Sandwich Islands. Among the ecological papers, Mr. J. Holmboe sketches the botany of the Norwegian moors. Mention should also be made of the notices in the *Beiblätter* of addresses delivered before the Society of Systematic Botanists, of which not the least interesting is that by Prof. K. Fritsch discussing the systematic position of the monocotyledons.

The index to the first thirty volumes published in 1904 is an important reference book to systematic botany from 1881; the systematic index, and the catalogue under countries, will be found most useful.

The Practical Photographer. Edited by the Rev. F. Lambert. (Library Series.) No. 27, *Photographic Optics and Lenses,* pp. xxiv+64. No. 28, *The Optical Lantern for Projection and Enlarging,* pp. xxiv+64. (London: Hodder and Stoughton.) Price, each vol., 1s. net.

THESE two volumes form the December and January issues of this useful series of photographic handbooks. As usual, each is prefaced by a short essay on the pictorial work of some well known photographer written by the editor, and in these cases we are made acquainted with the photographic work of Mr. W. A. I. Hensler and Mr. Charles H. L. Emanuel. They are also accompanied by a series of reproductions from the best works of these photographers, which illustrate, more than words can describe, the particular styles of treatment.

In the volume on photographic optics we have a series of notes by numerous authors on various points relating to lenses. These are more or less miscellaneous in their nature, but the several items are generally clearly described, and may prove serviceable. Numerous diagrams and process reproductions are included in the text.

The volume on the optical lantern contains many useful wrinkles which will materially aid the beginner and prove useful to those who are already acquainted with the manipulation of a lantern. Forms of lanterns, illuminants, condensers, reflectors, are all fully treated, and in addition there is much miscellaneous information on lantern optics, and sundry items pertaining to lantern work. Included in these pages are process reproductions of several photographs, details about which are given under "Pictorial Notes."

The Sanitation of a Country House. By Dr. Harvey B. Bashore. Pp. vi+103. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1905.)

THIS little book would form a useful, popular, and non-technical guide on sanitary matters to anyone about to build a country house, but is necessarily one for America, and the practice recommended and details given would not always suit this country. The illustrations and diagrams, sixteen in number, are excellent.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Perkin Jubilee and Chemical Industries.

AT the meeting held at the Mansion House on February 26, with the Lord Mayor in the chair, many men of position and influence in the scientific world met to do honour to Dr. W. H. Perkin, and to agree to celebrate the jubilee of his discovery of the first coal-tar colour. Whilst all felt not only the importance, whether from a purely scientific or from an industrial point of view, of this discovery, and whilst they all applauded Perkin's researches in other branches of science and his modest and retiring bearing throughout, the fact could not be lost sight of that although England was the country in which the coal-tar industry was founded, it had practically, since those days, passed out of our hands into those of the Germans. The cause of this, I remarked, was not due to any want of knowledge or power on the part of Dr. Perkin himself, but rather to the absence of appreciation by capitalists and others engaged in industry of the importance of scientific method, or, in one word, to English Philistinism, the result being that the successful prosecution of a new industry the very existence of which depends on high scientific attainment was impossible. In corroboration of this opinion, which was also expressed in an excellent article in the *Times* a few days before the meeting, I ventured to direct attention to the fact that, being at that time (fifty years ago) engaged in building up a chemical school at Owens College, I knew three talented young German chemists whose names have since become watchwords in Germany (Caro, Martius, and Pauli) who were then employed in chemical works in Manchester and the neighbourhood. These men were intimately acquainted with the colour industry, both in theory and practice, so far as it had then advanced, and were perfectly capable, as was afterwards proved, of carrying it on successfully. Had they been supported by men of financial light and leading in Lancashire the industry might have flourished in this country. Not, however, finding the necessary support here, they returned to Germany, where they became the leading members of the great colour works at Ludwigshafen, Höchst, and Berlin.

But the Germans, not content with having secured an industry the value of which is reckoned at 50,000*l.* annually, are preparing for future attacks. On the very day of the Perkin meeting I received a letter from my friend Dr. Hagen, the director of the Physikalische Reichsanstalt in Charlottenburg, in which he informs me of the determination to found a corresponding Anstalt for chemistry, and in the last number of the *Berichte* I find a statement made by the committee of the German Chemical Society in support of this proposal. In this they point out, in the first place, that the due development of chemistry, influencing as it does so powerfully national life, cannot be ensured by individual effort, and that the establishment of a Reichsanstalt for chemistry is for this purpose necessary. In the second place, they proceed to indicate a large number of questions requiring solution which can only be satisfactorily answered by long-continued research. They conclude by the remark that such an institution must be of a national character, inasmuch as the subjects dealt with are of national importance, influencing the welfare and progress of the country.

Here we have a true trumpet call. Will England answer to it or will she otherwise make up her mind again to take a second place? In his admirable letter on "Science and the Industries" in the *Times* of Saturday, March 3, Prof. Silvanus Thompson points out that the electrical industry, and that of the manufacture of steel, are likely to fall, if they have not already fallen, into the hands of Germany and America, and insists, as many of us have been doing for the last twenty years, on the necessity of our commercial and educational leaders becoming aware of the absolutely vital nature of the bearing of scientific research on industrial prosperity. This conclusion is emphasised in a letter printed in the *Times* of March 6 from Sir Joseph Lawrence, in which he urges the plea that English manufacturers are too poor and too closely run by competition to be able to afford scientific leading! This is indeed an appeal *ad misericordiam!*

The long and the short of it is that the Germans, and the Americans I may add, see this, and are strenuously working the principle into practice, whilst we remain "blind leading the blind." When will our eyes be opened?

HENRY E. ROSCOE.

Cooperation between Scientific Libraries.

DR. BATHER's letter in your issue of March 1 is one which deserves the hearty support of all scientific workers, in the United Kingdom at least. I have long felt that the whole of the literature indexed in the International Catalogue ought to be available for reference in some one locality, and preferably in London. In my address as president of the Chemical Society in 1894, foreshadowing the time when our meeting-room would be too small, I ventured to point out that "This is a difficulty that threatens to oppress all the Burlington House societies, and must become more pressing as the importance of bringing all societies having cognate aims into juxtaposition is realised. Perhaps some day our friends and neighbours the artists will have found quarters elsewhere more suited for the display of their works—for they appear already to have far outgrown the space at their disposal, and to be therefore obliged to impose undesirable limitations on exhibitors; when this occurs, it should be possible to find accommodation more adequate to the needs of science and fit presentment of its Imperial importance" (Chem. Soc. Trans., 1894, 358).

Since then, the University of London has vacated the portion of Burlington House in which it long had its quarters, and the Royal Society has let slip a golden opportunity of securing these rooms for its own use, and at the same time of affording to other cognate societies—including the British Association—the increased accommodation they so much need. The quad. roofed in would make a magnificent reading-room. Sad experience teaches me that there is little hope in this country that those who are engaged in scientific work will consent to work together for some serious common purpose: apparently every little show must be run separately; but if they could be persuaded—if the Royal Society would for once have courage and lead—much might be done to further a project such as Dr. Bather advocates and bring it to a practical issue at no distant date.

HENRY E. ARMSTRONG.

THE letter of Dr. Bather on the above subject in NATURE of March 1 (p. 413) is of much interest.

My experience in the preparation of the Royal Society Catalogue of Scientific Papers fully confirms the statements of Dr. Bather and of Dr. Muir, to whose paper he refers, as to the inconveniences arising from want of coordination between different libraries.

When we were commencing the indexing of the scientific papers from 1884 to 1900, it was necessary to ascertain the names of new serials that had come into existence since 1883, and also to take note of the serials that had been omitted from the twelve volumes of the Catalogue already published. Members of our staff were sent to some of the scientific libraries in London, and a list was thus obtained containing more than 1400 serials of various degrees of importance. Many of these were, of course, unsuitable for our purpose; a large number, however, were incomplete, single volumes and sometimes single parts only being available. These separate portions had probably come to the various libraries as specimens, or for the purpose of obtaining exchanges; and if there had been a general agreement between the libraries of London, arrangements might have been made to maintain such serials complete in one or other of the libraries. If a joint handlist, as suggested by Dr. Bather, had been in existence, much time expended by us in searching for these serials would have been saved.

A few days ago I heard that the Royal Society of Edinburgh is engaged in considering a scheme of cooperation amongst the principal scientific libraries of Edinburgh and Glasgow, and that a complete list of scientific serials in these libraries is to be compiled. It would be of great advantage if a similar scheme could be carried out in

London. In the libraries of the learned societies at Burlington House alone there are many serials in duplicate; some of these might profitably be replaced by others which are not at present in these libraries. It often happens that books and serials are sent to library committees on approval, and are rejected because they are thought to be more suitable for other libraries; but attempts are not always made to ascertain whether these other libraries possess them. At the present time, from want of space and other causes, the duplication of periodicals at Burlington House is avoided as much as possible.

In the subject index to the scientific literature of the last century which the Royal Society is preparing, it is proposed to indicate, in the introductory list of serials, the libraries in which the cataloguing has been done, and also to mention other libraries in which the books may be found. This will be useful to workers, but it cannot be quite complete, for the task would be too great to undertake in its entirety. For example, there are more than 600 serials which contain mathematical papers, and it would be impossible to name all the libraries where they are found.

March 3. HERBERT MCLEOD.

The Bees of Australia.

UP to the beginning of 1905, 224 species of wild bees had been recorded from Australia, no less than 183 of them having been described by F. Smith, of the British Museum. I had the opportunity in 1904 to study Smith's types at the British Museum, and since then I have worked up the unnamed Australian material belonging to that institution, with the exception of some species of Halictus yet to be examined. The following list shows the genera found in Australia (including Tasmania), New Zealand, and the Austro-Malay Islands (taking the region as defined by Wallace), and the number of species in each.

Family.	Genus.	Australia.	New Zealand.	Austro-Malay Islands
Colletidæ	Phenacolletes *	1	—	—
	Paracolletes (sens. lat.)	52	8	—
	Anthoglossa *	4	—	—
	Cladocerapis *	1	—	—
	Andrenopsis *	1	—	—
Prosopidæ	Hylæoides *	2	—	—
	Callomelitta *	1	—	—
	n.g. aff. Callomelitta*	1	—	—
	Prosopisteron *	1	—	—
	Euryglossa *	29	—	—
	Prosopis	54	7	6
	Stilpnosoma *	2	—	—
Andrenidæ	Sphecodes	1	—	1
	Halictus	22	3	1
	Parasphecodes *	18	—	—
	Nomioides	1	—	—
	Meroglossa *	1	—	—
	Nomia	19	—	21
	Stenotritus *	2	—	—
	Andrena ?	3	—	—
Family ?	Gastropsis *	2	—	—
Panurgidæ	Scrapter ?	2	—	—
Ceratinidæ	Ceratina	—	—	6
	Exoneura	5	—	—
	Allodape	3	—	1
Xylocopidæ	Xylocopa	2	—	27
	Lestis *	2	—	—
Anthophoridæ	Anthophora	11	—	6
	Saropoda	2	—	1
	Tetralonia	1	—	—
Melectidæ	Crocisa	8	—	7
Nomadidæ	Nomada	—	—	2
Megachilidæ	Megachile	50	—	57
	Lithurgus	4	—	—
	Thaumatosoma	1	—	—
	Ctenoplectra	—	—	1
	Coelioxys	2	—	4
	Parevaspis	—	—	1
	Anthidium	—	—	1
Apidæ	Apis	(1 introd.)	—	3
	Trigona	5	—	7
		317	18	153

The list proceeds from the most primitive bees up to the most specialised. The genera marked with an asterisk are wholly peculiar to Australia, so far as known; and it will be observed that, as with the mammals, there are many endemic genera of a primitive type. Lestis is the only endemic genus allied to the ordinary long-tongued bees, and that consists of two closely allied species, which represent an offshoot from Xylocopa, probably not of very ancient date. True Xylocopa, it will be noticed, just enters Australia (but one species is common in the north), but is rich in species in the Austro-Malay Islands, and extends into Asia, Europe, Africa, and America. The Xylocopas are the large carpenter bees, which nest in wood, and may be transported across the water in floating trees. Until recently, the genera Thaumatosoma and Exoneura were supposed to be peculiar to Australia, but the first has now been found in Burma and the second in Syria. They may possibly be genera which are verging on extinction, but as each differs only in one important particular from its nearest ally (these allies being Megachile and Allodape respectively), it is not impossible that they arose by parallel mutations in the widely distant localities in which they occur, quite independently.

The most interesting of the primitive genera is Phenacolletes, based on a new species (*P. mimus*) discovered by Commander J. J. Walker on the *Penguin* Expedition. The Colletid bees are supposed to have been derived from the fossorial wasps, and Phenacolletes is so like certain wasps that I was not sure whether it was a wasp or a bee until I had examined its pubescence with a compound microscope. Unfortunately, we know nothing of the habits of this insect, but Commander Walker kindly informs me that it was taken on November 12, 1890, at Turtle Bay, north end of Dirk Hartog Island. He finds in his journal for that day that "an upright growing shrub with ovate glabrous leaves and large whitish-rosy mallow-like flowers" was the only plant which seemed to be at all attractive to insects, so perhaps the Phenacolletes came off that.

I have supposed that the bees with emarginate tongues (Colletids and Prosopids) arose from the wasps independently from those with pointed tongues, this seeming the more likely, because the wasps themselves exhibit both types. However, there are indications that in Australia the first form may have become modified into the second within the limits of the bee-group. This is especially suggested by the tongue of Callomelitta, and by one of the new species placed for the present in Paracolletes.

The new genus allied to Callomelitta, indicated in the table, is for *Sphecodes antipodes*, Smith. Colonel Bingham very kindly made a critical examination of this species at my request, and found that it was not a Sphecodes, but belonged to a new genus differing from Callomelitta in the shape of the thorax, pubescence of hind tibiæ, &c. It will undoubtedly prove an important form from the standpoint of the evolutionist.

The species marked as Andrena? and Scrapter? stand in our lists as members of these northern genera, but they have not been critically examined recently, and it is questionable whether they are rightly classified. The name Mellitidia has been applied to the so-called Andrena of Australia, and it is probably valid. Nevertheless, there are some undoubted cases of well known northern genera having endemic Australian species, while they have none, so far as known, in the Austro-Malay region. These are Nomioides (found from Burma to Europe) and Tetralonia (India to Europe, &c.); Saropoda (also European) is really in the same category, as the single Austro-Malay species is one of the Australian ones, which has reached the Aru Islands. The case of the Tetralonia seemed a little doubtful, but Colonel Bingham has critically examined Smith's type, and reports that it is a true Tetralonia, but is a female, not a male, as Smith had it. Lithurgus is also a genus of Europe and Asia, and likewise Africa, which has Australian species, though none are known from the Austro-Malay islands. In this case, it is practically certain that the genus is dispersed more or less through the islands, and has been overlooked, for one of the Australian species is exceedingly close to one of India.

Gastropsis, placed by Ashmead in the Andrenidæ, is apparently allied to the European Meliturga, and is in a

way intermediate between the two groups (long-tongued and short-tongued) of pointed-tongued bees. Cladocerapis and Prosopisteron are extraordinary endemic genera, which do not lead in the direction of anything known elsewhere.

It will be observed that the native bee-fauna of New Zealand is very poor, and quite lacking in distinction. Two of the genera are world-wide, while the third (Paracolletes) is found only in New Zealand and Australia, the species of the two regions being quite closely allied. It would seem that New Zealand received its bees in comparatively recent times from Australia (one of the species of Prosopis is even identical with an Australian one), and it may be added that all the affinity is with the southern part of Australia, especially Tasmania. There is still a possibility, of course, that New Zealand may contain some ancient endemic genus, which is now rare and has been overlooked by collectors.

The bees of the Austro-Malay islands are not at all adequately known, though we have a good idea of the general facies of the fauna. Most of the species were discovered by Wallace; I find that about a dozen were known before Wallace went to the islands, about seventy-four were added by him, and sixty-six have been discovered since. The species of Celebes are best known (41), but from Amboina we know only 9, Lombok 3, Timor 8, Ceram 3, Bourn 3, New Caledonia 4, Timor Laut 1, and so forth. It is evident that a very rich field lies before the collector in this region; but it is curious that so far we have not a single endemic genus of bees from the Austro-Malay islands, and it appears probable that few or none exist. Instead, we have numerous species of widely dispersed tropical genera; a varied, but not, apparently, very isolated fauna. The contrast with Australia is extreme. Of the eighteen genera represented, only six are even confined to the eastern hemisphere, these being Crocisa,[1] Allodape, Aspi, Saropoda, Ctenoplectra, and Parevaspis.

To sum up, it is apparent that Australia posesses a very old and long isolated bee-fauna, containing types which seem to link, in greater or less degree, the bees and fossorial wasps, the emarginate-tongued and pointed-tongued bees, and the long-tongued and short-tongued bees. It is therefore evident that the study of this fauna is likely to yield much of interest in the future; and, it must be added, there is little doubt that the number of species awaiting discovery far exceeds the number already discovered. On the other hand, we find in Australia also a more modern fauna, containing even a few species quite identical with those of the Asiatic mainland, and several closely allied thereto. Such are certain species of Nomia, Xylocopa, Anthophora, and Trigona. Of such forms, it appears that they are either strong fliers (as Anthophora) or else they have the habit of nesting in trees (as Trigona), and thus it is not difficult to understand how they crossed the sea. None of these genera, however, have reached New Zealand, which is not only too remote, but also out of the path of suitable marine currents. In the case of certain cosmopolitan genera which have numerous Australian species, such as Prosopis and Megachile, it is to be noted that only a few of the species are specially related to those of the Malay Islands and Asia; the others constitute part of the peculiarly Australian fauna, although they have not become generically altered.

T. D. A. COCKERELL.

University of Colorado, Boulder, Colorado, U.S.A.

The Intelligence of Animals.

IN his review of Father Wassmann's book (NATURE, February 1, p. 351) Lord Avebury dissents from Father Wassmann's conclusion that the sagacity of ants is "instinctive and essentially different from intelligence and reflection," and repeats the opinion which he has held for many years, that "it is difficult altogether to deny to them the gift of reason." The following incidents, which I observed on a footpath in the Donetz Coalfield, in Russia, in the summer of 1898, appear to me to show that the insects here referred to possess both intelligence and the gift of reason, and, therefore, to lend a general support of Lord Avebury's views.

Numerous small black-beetles, about three-eighths of an inch in length, were busily engaged in rolling, hither and thither, balls of cow-dung, about half an inch in diameter, which they had cut away from the edge of a still soft mass of that substance that lay near the middle of the path. As a rule, two insects were engaged in rolling each ball, both walking on their hind legs with their fore-feet resting on the upper curve of the ball—the one behind pushing and walking forwards, the one in front pulling and walking backwards. When the ball commenced to roll on any declivity it passed over the body of the one in front, which then lost its hold and was left behind. But the other always held on tightly to the ball, and was carried over and under it, several times in succession, until the ball either ceased rolling or the insect was thrown off. In the latter case the beetle followed to the bottom of the slope on foot, and usually recovered the ball without difficulty.

The principal slope upon which these disasters happened constituted one bank of a small dry water-course about six inches deep. The length of the bank from top to bottom was ten or twelve inches. The dry bed of the water-course was slightly inclined. In one instance, in which the beetle was thrown off at the fourth or fifth revolution of the ball, the latter rolled to the bottom of the bank, and then, turning at right angles to its former direction, continued to roll down the bed of the water-course to a further distance of nine or ten inches. The beetle followed to the foot of the bank, but did not find the ball where it obviously expected to do so. After hesitating and moving about in various directions to a distance of an inch or two, it ran down the bed of the water-course to a distance of three or four inches, returned, ran down again to a greater distance, returned a second time, then ran down to within two inches of the ball, but, failing to find it, gave up the quest and climbed up the bank to the level part of the path. All its movements, from the time it was forcibly parted from the ball, had the appearance of being dictated by intelligence and reason.

Again, a solitary beetle rolling a comparatively new ball had reached a distance of nine or ten inches from the heap when a second unoccupied beetle coming from the opposite direction stood up in front of the rolling ball as if with the intention of pulling it forward and assisting the first. Instead of doing so, however, it brought the ball to a dead stop. In vain the first beetle tried to move the ball; the second held it fast. The first then got down and peered round the side of the ball, apparently with the object of ascertaining the nature of the obstacle. While this examination was proceeding, the second, with its fore-feet still resting on the upper part of the ball, neither pushed nor moved in any way. The first then stood up again behind the ball and pushed it as before, but still the ball did not move. For the second time the beetle got down, made an examination as before, then, crouching with its back well under the lower curve of the ball, heaved with all its might—in the same way as a workman does in similar circumstances—but the ball remained stationary. The first beetle then came out from under the ball, and was proceeding round its right-hand side, with some new intention, when the two seemed to catch sight of each other. The second beetle threw itself on the ground with the quickness of thought, and fled pursued by the other, both running at their utmost speed. Fear, and a sense of guilt, seemed to spur the flight of the one, resentment and anger the pursuit of the other. In a chase which was continued for a distance of six inches, the fleeing beetle, which had started with an advantage of about an inch and a half, increased the distance between its pursuer and itself to more than two inches, when the former, seeing the futility of further pursuit, stopped, returned to the ball, and resumed its occupation of rolling it.

The reason why the second beetle stopped the ball, remained absolutely motionless when the other got down to reconnoitre, and ran away when it saw it was discovered is not apparent. Dare we suppose that it was simply amusing itself at the expense of the other? This was the impression left on my mind at the time.

W. GALLOWAY.

[1] Crocisa has been reported from the neotropical region, but the species are probably not correctly referable to that genus.

Result of War affected by Soldier's Stature.

IN your issue of March 1 Major-General Warrand denies that the chance of being shot in war depends, *ceteris paribus*, merely upon the square of the soldier's stature.

He would therefore introduce another factor, the thickness of the body, which presents a target varying in size according to the direction from which the fire comes.

This, however, is unnecessary. The stature alone should be considered, because, for the sake of simplicity, we assume that oblique fire is experienced equally by both armies, and we also assume that all soldiers are of similar build. The assemblage of human targets in each army is therefore proportional in size to the square of the average stature.

JOHN HILL TWIGG.

The Hydro, Ben Rhydding.

WHAT IS WHISKEY?

DURING the last three months readers of the daily Press have from time to time been the recipients of informations concerning the nature of whiskey. Their education must have been somewhat heterogeneous in that what whiskey should or should not be seemed to change each week, in accordance with the witness whose evidence was being reported; perhaps now the so-called whiskey test case is over it will be convenient to place before our readers some of the most important facts brought to light by it.

The borough of Islington began its work in the matter of potable spirits with brandy, and succeeded in practically enforcing for this article of commerce a chemical standard. This standard, as in the case of the one which it has, at any rate for the time, succeeded in establishing for whiskey, is a minimal standard, ***i.e.*** brandy must contain at least a certain proportion of so-called compound ethers, and whiskey must, if the judgment in this case be maintained, at least contain a certain proportion of so-called impurities, viz. substances other than ethylic alcohol and water. Before dismissing from our notice the brandy standard, we would emphasise the fact that in the case of brandy a minimal amount of one class of by-product, the individual members of which almost certainly have the same therapeutic effect, is demanded. In the case of whiskey, the Islington magistrate fixed a chemical standard based upon an analytical, not chemical or even therapeutical, entity containing such different substances as compound ethers, higher alcohols, acids, and aldehydes. He further strictly enjoined the kind of apparatus in which whiskey must be produced, and the materials which shall in the two countries producing whiskey be solely used in the mash from which the spirit is to be distilled. The question of a chemical standard for brandy, and the protection which such a standard affords to the public, was thoroughly discussed in NATURE of November 3, 1904. The anomaly of having a fixed minimum and no fixed maximum for alcoholic impurities in potable spirits is too palpable to need amplification, and has been definitely recognised by the Belgian authorities, who refuse to allow the sale of a potable spirit possessing a coefficient of impurities of more than 300. This fact is of special interest at the present time, for if the Islington judgment is to stand, no potable spirit can be sold as whiskey which, *inter alia*, possesses a coefficient of impurities of less than 380.

To the average reader the judgment containing the definition of what for the future must be sold as Irish and Scotch whiskey would read, and it consists of some five thousand words, as if this question had never been considered before; and, indeed, a leading article upon this subject which appeared in a medical contemporary last week contained the extraordinary statement that "five years ago there was no suggestion even that potable spirits might be brought within the operation of the Sale of Food and Drugs Act, with a view to the detection of foreign or added spirit." It can scarcely be news to the readers of NATURE that a Select Committee under the chairmanship of Lord Playfair was appointed in 1891 to inquire into precisely the same question as was laid before the Islington magistrate, and had at its disposal practically the same material; it examined numerous witnesses, chemical, physiological, and commercial, and reported in 1891.

The best way of criticising Mr. Fordham's judgment is to summarise carefully the conclusions of this committee. At the onset it is a relief to find that upon one point at least they agree, viz. that according to both there is no evidence that any potable spirit sold in the United Kingdom as whiskey contains constituents other than ethylic alcohol which are injurious to health; in other respects we are afraid the Islington magistrate in his judgment is diametrically opposed to the report of this committee. Perhaps the shortest way of dealing with this report in the present article is to quote verbatim the Committee's view with regard to the definition of whiskey.

"Your committee do not attempt a legal definition of whiskey. Whiskey is certainly a spirit consisting of alcohol and water, with a small quantity of bye-products coming from malt or grain, which give to it a peculiar taste and aroma. It may be diluted with a certain quantity of water without ceasing to be whiskey, and it may be diluted with spirits containing little of the bye-products to suit the pocket and palate of customers, and it still goes by the popular name of whiskey. Your committee are unable to restrict the use of the name as long as the spirits added are pure and contain no noxious ingredients." Then again :—"There are varieties in the purity of patent or silent spirits. When they are made for blending it is the object of the distiller to retain a percentage of bye-products, though to a smaller extent than in pot-still whiskey."

We cannot think that the Islington magistrate was not aware of these conclusions, although it is exceedingly odd that in so lengthy a judgment no mention is made of the report of the select committee. However, the Islington dicta with regard to whiskey are certainly clear. Irish and Scotch whiskey must be produced by the distillation in a pot-still of the wort derived from a mash consisting in Ireland of 75 per cent. barley malt and 25 per cent. indigenous grain, in Scotland of barley malt alone. We are not told what kind of pot-still is to be used, although it is quite clear to anybody who has studied the subject that, with regard to the degree of rectification capable of being produced, pot-stills differ *inter se* as much as the patent-still differs from the pot. Whether or not the chemical standard of the Islington analyst is also to be maintained is not quite clear, but if so it appears that at least some of the pure malt pot distilleries will have to modify their technique. So far as concerns the actual term whiskey itself, it is not stated definitely that this term, provided it be not prefixed by the epithet Scotch or Irish, should be refused to blended whiskies, that is, to whiskies consisting in some part of patent-still or grain spirit, provided they consist of "a very considerable proportion" of pot-still whiskey. If these blended whiskies are to conform to the chemical standard laid down by the Islington analyst, practically all the blended whiskey on the market at the present day will have to undergo a considerable alteration. It is to be noted that, as distinct from the report of the Select Committee, no

importance is attached by the Islington magistrate to the question of taste or flavour, and no limit is placed by him upon the amount of chemical impurities which whiskey may contain. Although there is scanty reason to believe that the higher alcohols, furfural, and compound ethers in the proportion in which they exist in pot-still whiskey as ordinarily consumed are injurious to health, yet, nevertheless, one cannot view with complaisance a legal definition of whiskey which allows the quantities of these substances to be unlimited. The only safeguard which the public will have will be their own taste. They have shown distinctly what they like in that nine-tenths of the whiskey consumed to-day consists of a blend, with more or less pot-still whiskey, of this same patent-still whiskey, which is to be whiskey no longer, because technologically, if not chemically and dietetically, it diverges too widely from the mediæval and sentimental "usquebaugh."

Two further points in the judgment of the Islington police magistrate will be of interest to technologists; the first is the absolute condemnation of maize as a constituent of the mash from which whiskey is to be made. This is especially interesting because to those cognisant of the literature of the subject this question of maize as a constituent of brewing and distilling mashes is by no means a new one. Although precedent seems to be no justification at Islington, it is a fact that maize was used as a constituent of distilling mashes previous to 1881. We choose this date advisedly, because in 1881 the use of this same opprobrious maize as a constituent of brewing mashes was by the Free Mash Tun Act actually legalised. Again, the Select Committee on bonded spirits was fully cognisant of the use of maize in distilling mashes, and in its report of 1891 had nothing to say against this grain. Still further, in 1898 the Beer Materials Committee, after a most exhaustive inquiry, refused to prohibit the use of maize. Lastly, the American Pharmacopœia, which includes whiskey as an official preparation of alcohol, specifically states that it may be made from maize. So far as we can gather, the objection to maize is that it cannot be, or at any rate is not, ripened in this country.

The last point which we have space to consider is the statement that, apart from taste and flavour, patent-still whiskey has a different effect upon the consumer from pot-still whiskey. It is true that the therapeutic evidence at present at our command upon this subject is somewhat scanty, but what there is points to the conclusion that practically the only active constituent in whiskey is ethylic alcohol, and that if a given dose of whiskey differs otherwise than in taste and flavour from a proportional amount of pure ethylic alcohol equally diluted, this difference is due entirely to the presence of certain compound ethers. Now as a matter of fact, although patent-still whiskey contains a smaller coefficient of impurities than pure pot-still whiskey, the ethereal moiety of the impurities is approximately the same in both. At any rate, the amount of compound ethers taken in an ordinary dose of patent-still or blended whiskey so nearly approximates to that taken in any ordinary dose of pot-still whiskey that no therapeutical difference is, *a priori*, to be expected between the two beverages as consumed. The direct evidence we have upon this subject bears out this *a priori* reasoning.

Over and above the details which have been brought to light in these whiskey prosecutions, everyone must be struck by the curiousness of a legislation which allows disputes of this kind to be decided in a police court. During the past few years many special committees have sat upon subjects relating to the working of the Sale of Food and Drugs Act, and not a few of them have specifically recommended either the institution of a permanent court of reference for these matters or at any rate that they should be laid before some specially organised tribunal. It is sincerely to be hoped that before long these recommendations may be adopted.

THE ROYAL COLLEGE OF SCIENCE.

THE relation between the University of London and the proposed new Royal College of Science has been the subject of some discussion since the publication of the report of the departmental committee on the college, described in our issue of February 8 (p. 344). It is devoutly to be hoped, however, that the consideration of this matter will not divert attention from the essential point of the committee's report, namely, "that it is desirable that the new institution should be established immediately, and that its organisation should proceed without delay." Divergent views may be held as to the nature of the connection between the University and the new College, but there can be no two opinions as to the folly of delaying the establishment of the institute, as recommended by the committee, while questions of control are being decided.

The subjoined letter from Mr. C. McDermid, hon. secretary to the British Science Guild, appeared in yesterday's *Times*, and the plea of urgency contained in it is endorsed in a leading article in the same issue.

I am directed by the executive committee of the British Science Guild to request you to be good enough to give publicity to the following expression of the views of the committee on a matter of great national importance.

The departmental committee on the Royal College of Science has shown in its final report that a start can at once be made to provide for the most advanced instruction and research in several branches of applied science, which all are agreed are imperatively necessary in the interests of our national industrial progress.

The danger of delay in giving effect to the recommendations of the departmental committee is recognised by the leaders in science and industry, who are largely represented among the members of the British Science Guild.

The Government have signified their willingness to hand over to a new governing body the present buildings of the Royal College of Science and Royal School of Mines, the new chemical and physical laboratories, which are approaching completion, and some adjacent acres of land on which to erect new buildings. In addition to this it is understood that the Commissioners of the 1851 Exhibition will provide an additional building site, and that the council of the City and Guilds of London Institute will cooperate in the scheme.

The Government are prepared to provide a yearly grant about equal to the interest at $2\frac{1}{2}$ per cent. on one million pounds sterling, and there is reason to hope that the London County Council will vote an approximately equivalent sum. In addition to this there is the munificent gift of 100,000*l*. from Messrs. Wernher, Beit, and Co., and the sum that it is expected will be provided for the equipment of the new mining and metallurgical laboratories as the central object of a national memorial to the late Sir Henry Bessemer.

In view of all these most favourable conditions the executive committee of the Guild earnestly hope that neither the question of the ultimate and final relationship of the new institution to the London University nor any other matter will be allowed to interfere with the immediate appointment of at least an organising governing body. This body might deal *inter alia* with the status and qualifications of the professional staff required and obtain detailed expert advice with regard to the new buildings to be erected.

Probably no more propitious time for founding a college of the kind contemplated could be offered

than the present. The Perkin jubilee has been the means of arousing a certain amount of interest as to the cause of lost industries, and the remedies to be applied if we are to secure industrial progress in the future. Enlightened manufacturers are prepared to give substantial support to an institution which will aim at bringing scientific knowledge in close relation with industries and industrial needs. Not to take advantage of the present desire for action would be dilatory policy; and if the scheme is held up while discussion takes place upon its academic aims and relationships, nothing could be more disappointing to those who are anxious to see the establishment of an institute capable of rendering great service to the community.

In the proposed new college no provision is to be made for biological subjects; and Prof. Ray Lankester has written a letter to Lord Rayleigh, president of the Royal Society, pleading for the recognition of the fact that the needs and the importance of these sciences are as great or greater, and that they are at present well-nigh destitute of any endowment, or of adequate provision at the public charge of laboratories and the means of research. Prof. Lankester shows that there are many branches of applied biology of importance to the State, and though he does not propose any formal action to the council of the Royal Society he trusts "that means may be devised of obtaining an assurance from the Government of not merely continued, but increased, provision for the highest work and training in the various sciences of the biological group—including geology."

PROF. SAMUEL PIERPONT LANGLEY.

AT the zenith of his reputation, and possessed of his full capacity for work, America and science have to regret the death of Prof. Langley, who for nearly twenty years directed and controlled the energies of the Smithsonian Institution. The objects promoted by such an establishment are so varied, the interests that it has to maintain are so numerous, that its direction can only be confidently entrusted to one who combines the skill of the administrator with the training of the man of science. The energy displayed by Prof. Langley in the conduct of the Smithsonian Institution, and its steadily increasing influence under his direction, show that he loyally appreciated the intentions of the founder, and that he proved himself a worthy successor to Joseph Henry and Spencer Baird, names still warmly treasured in the memory of the American nation. We may recall, though we cannot do justice to, some of the more important features that have marked his connection with the institution. His supervision of the museum, and his earnest endeavour to make it more valuable for instructed and uninstructed alike, led to rearrangement, and especially to the foundation of the children's room, a feature which may serve as a model for similar institutions. The Bureau of American Ethnology is a national undertaking that has long been conducted on spacious lines, but under the late director this department has assumed magnificent proportions, the care of which was an enormous responsibility that even the assistance of able colleagues could not wholly remove. The publications of this bureau show only the thoroughly digested scientific conclusions, and represent but a fragment of the immense amount of work actually accomplished. But, perhaps, in the establishment and management of the zoological park we see the personal influence of the director most conspicuously exhibited. It was his dream to establish a park in which the wild animals of his native land might live as nearly as possible under conditions natural to them, so that they might breed and thrive in captivity as in their native haunts. The difficulties in the way might well have daunted one less enthusiastic. More than once the question of abolishing the park has been considered, and over and over again he had to fight the battle in the teeth of hostile or indifferent politicians, who could not be made to appreciate the value of the scheme, or to recognise that the preservation of the native animals, threatened with extinction, was a trust committed to their charge. He lived to see this scheme placed on a permanent footing, and if on a more modest scale than he could have wished, he could feel that his insistence had not only preserved the nation's heritage of wild animals, but had opened up important regions of biological research and of zoological art.

But, notwithstanding the severe demands the care of such an establishment must make, Prof. Langley did not allow his activity to be wholly absorbed in the interests of the Institution. He never forgot that he was a physicist and an astronomer before he became an administrator. As a physicist, the problem of flight largely engaged his attention, a subject to the consideration of which he was led by his studies on the internal force of the wind. To what extent his experiments advanced the problem of aviation it would be premature to pronounce. The form of aërodrome which he favoured was capable of making flights of a mile, unsupported except by the mechanical effects of steam engines. But these successful flights were carried out on models. The application of the same principle to larger machines was, as he contended, never fairly tried. The launching apparatus was ineffective, and his machine never got into the air at all. But if its capacity for sustained flight was never tested, some of the mechanical features that he tried and adopted will no doubt find their place in later constructions. As an astronomer he will be remembered for his direction of the Allegheny Observatory and the important work which he accomplished there on the sun and in the department of spectroscopy. His drawings of the solar surface, made nearly forty years ago, remain unsurpassed for delicacy and truthfulness, while his views on the physical constitution of the sun are worthy of the closest attention. As an experienced observer of solar eclipses he was also well known, and thirty-five years ago, when the spectroscopic examination of the sun's surroundings had made but little advance, he rendered yeoman service. The invention of the bolometer constitutes a distinct claim on our gratitude. This sensitive instrument affords the means of measuring minute changes in heat arising from the change in the electrical resistance of an extremely thin strip of metal. By its use Prof. Langley showed that the corrections for atmospheric absorption, deduced by earlier observers with less perfect instruments, are all too small, and consequently the generally received value of the "solar constant" has been considerably increased. With the same instrument our knowledge of the infrared spectrum has been greatly increased. The heating effects from rays unsuspected in previous investigations have doubled the known extent of the solar spectrum. By the aid of rock-salt lenses and prisms Prof. Langley was able to show that bands of atmospheric absorption were found to alternate with bands of solar radiation, a fact of no inconsiderable importance in terrestrial meteorology.

As a writer the late director of the Smithsonian Institution was well known for his powers of graphic description and vivacious style. His "New Astronomy," published many years ago, attracted very

considerable attention, and did much to popularise the science in America. It is needless to say that he was a member of many learned societies, American and European; it will be sufficient to refer here to the fact that he was elected a foreign member of the Royal Society in 1895. At the age of seventy-two he is removed from that position he was so well fitted to adorn, and the respectful sympathy of the men of science of all nations will be offered to those who suffer by his loss.

W. E. P.

NOTES.

ONE good purpose served by the movement referred to last week (p. 419) to commemorate the jubilee of the discovery of the first artificial coal-tar colour by Dr. Perkin is that public attention has been directed to the relations between scientific research and industrial progress. The complete lack of sympathy between the capitalist in this country and the scientific worker, largely due to the indifference shown by statesmen to scientific studies, has been persistently deplored in these columns for many years; and we are glad that the general public is now being enlightened as to the results of neglect of scientific research. The coal-tar industries, founded upon an essentially British discovery, have been lost to us, and are now represented in Germany by two industrial groups which, with a capital of 50,000,000*l.*, can pay dividends of from 20 per cent. to 30 per cent. per annum. Prof. S. P. Thompson, in a letter to Saturday's *Times*, refers to this lost industry, and shows that the electrical industry and the manufacture of steel must pass to other countries unless our manufacturers realise the industrial value of higher technical education and scientific research. "Pioneering," he remarks, "as it is understood in an electrical factory in the United States or in Germany, is now almost non-existent in England; and the result on the electrical industry in the next ten years must be simply disastrous. Where are the newer kinds of electric lamps being developed? The Nernst lamp, the flame lamp, the vapour lamp, the oxide lamp, the osmium lamp, the tantalum lamp, all rich in future possibilities, where are they being perfected? Not in England. I doubt if there is a single British firm that is spending on such development a tenth part of the sum that one single American firm is spending on this one thing alone. If we cease to pioneer we become mere followers at a distance of those who are going forward—ourselves cease to lead in the development of the industry." To save our country from future disaster, our commercial and educational leaders, and our statesmen, must realise the vital nature of scientific research to national prosperity, and act upon this conviction by making adequate provision for it.

THE town council of Hamburg has voted the sum of 586,000 marks (29,300*l.*) for the construction of a new observatory at Bergedorf, about ten miles from Hamburg, and 309,000 marks (15,450*l.*) for the instrumental and electrical equipment of the observatory.

PROF. W. OSLER, F.R.S., has been elected a member of the Athenæum Club under the provisions of the rule which empowers the annual election by the committee of nine persons "of distinguished eminence in science, literature, the arts, or for public services."

THE American Geographical Society has awarded Captain R. F. Scott its gold medal in recognition of his services as commander of the British Antarctic Expedition. The Paris Geographical Society has awarded one of its gold medals to Major C. H. D. Ryder in recognition of his work as surveyor and explorer in connection with the recent Tibet mission, and his expedition to the sources of the Brahmaputra.

THE Berlin correspondent of the *Times* states that on Monday the German Emperor formally opened the new Museum for Marine Science, Berlin University. Among those present at the opening ceremony were the Prince of Monaco, the Rector of the University, Geheimrath Diel, and many distinguished representatives of natural science. The institute, which owes its existence to the direct initiative of the German Emperor, is intended to promote and encourage the interest of the German people in marine matters, and to place the subject upon a scientific basis.

THE Empress Frederick Institute for the higher scientific and practical education of medical men, which owes its inception to a project initiated by the late Empress Frederick, was opened in Berlin on March 1. The German Emperor and Empress, accompanied by many members of the Prussian Royal Family, were present. Sir Felix Semon attended the ceremony in accordance with the commands of King Edward, and in the course of a short address referred to the King's personal interest in the new institution.

A ROYAL COMMISSION has been appointed to inquire into the canals and inland navigations of the United Kingdom, and to report on their present condition, financial position, the facilities, improvements, and extensions required to complete a system of through communication by water, the expediency of canals being made or acquired by public bodies, and other matters related to these subjects.

SIR EDWARD FRY will preside at the twenty-third annual congress of the Royal Sanitary Institute, which will be held at Bristol from July 9 to 14. The presidents of the various sections will be:—Section i., sanitary science and preventive medicine, Sir William J. Collins, M.P.; section ii., engineering and architecture, Mr. Edwin T. Hall; section iii., physics, chemistry, and biology, Dr. W. N. Shaw, F.R.S.

AT the third International Seismological Conference, held at Berlin on August 15, 1905, Signor Luigi Palazzo was elected vice-president of the permanent board of the International Seismological Association. As Prof. A. Schuster was unable to accept the presidency offered him, the assembly deputed Signor Palazzo to act as president until the new elections take place next summer. Signor Palazzo desires it to be known that the Italian Government has consented to his acceptance of the office and responsibility, and he asks for the support of all who take an interest in the progress of seismology.

DR. C. W. ANDREWS, of the British Museum, left England last week to resume the quest for the remains of extinct vertebrates from the Tertiary deposits of the Fayûm and other parts of Egypt. Recent discoveries in Egypt have demonstrated the descent of the Eocene zeuglodonts from creodont Carnivora, and it is one of the objects of the present expedition to endeavour to discover, in higher beds, the missing links between zeuglodonts and true cetaceans. It may be added that the present expedition (like the earlier ones) of Dr. Andrews has been rendered practicable by the generosity of Mr. W. E. de Winton.

Science reports that, according to a despatch to the daily papers from Washington, the Carnegie Institution has purchased a tract of six acres in the north-west section of Washington, near Rock Creek Park, where it will erect a permanent home. The site is near the building of the

United States Bureau of Standards, and is in a commanding position, overlooking the entire city. The purchase price was 700*l.* an acre, and a building to cost 20,000*l.* will be erected at once.

THE great horticultural exhibition, to be held in the gardens of the Royal Botanic Society on Wednesday, June 13, will be opened by Princess Alexander of Teck.

THE Badische Anilin- und Soda-Fabrik, of Ludwigshafen, proposes to lay down a hydraulic power plant for the preparation of nitric acid from atmospheric nitrogen by the Birkeland process. Instead, however, of preparing calcium and sodium nitrate for artificial manures, as in the Norwegian installations, it is intended, in the first place at least, to make potassium nitrate for explosive purposes.

ACCORDING to the *Chemiker Zeitung*, the proposed new offshoot of the General Electrical Company, Berlin (p. 421), for the manufacture of mercury lamps in Europe is to be known as the "Quarzlampengesellschaft." The great advantage of the lamps will be the possibility of preparing them for all voltages up to 500 volts, and, in addition to the fact that no carbons are required, the lamps should be usable for 1000 hours without attention; it is expected that the lamps will in many cases replace arc-lamps.

AT the meeting in the Aula of the Berlin University on February 21, which was held at the invitation of the preliminary committee appointed last year to investigate the question of the formation of a Chemische Reichsanstalt, there were present some 150 of the most eminent representatives of German academic and industrial chemists, as well as several representatives of the Prussian Board of Education. After a few remarks by the president, Prof. Emil Fischer, the report of the preliminary committee was presented by Prof. Nernst. The great majority of the scientific and industrial societies consulted were decidedly in favour of such an institution; sympathetic answers were also received from most of the different German States and from the Imperial Government offices. Prof. Ostwald, who referred to the experiences gained during his recent stay in America, spoke of the necessity of the proposed institute from a scientific point of view, while Prof. Duisberg spoke from the technical side. After further discussion, the meeting unanimously agreed to the plans submitted by the preliminary committee, and moved that the Imperial Treasurer be approached on the subject. It is proposed that the institution be placed either in Berlin or in one of the suburbs; further particulars and details of the proposed scheme will be given in a subsequent issue.

A REUTER message from Rome states that the convention for the establishment of an International Institute of Agriculture has been signed by Italy, Russia, Servia, Belgium, San Salvador, Portugal, Mexico, Luxemburg, Switzerland, Persia, Japan, Ecuador, Bulgaria, Spain, France, Denmark, Greece, Sweden, Holland, Uruguay, Germany, Nicaragua, Austria-Hungary, Great Britain, Egypt, the United States, and Cuba. Other Powers have notified their intention of signing the convention. The creation of the International Institute of Agriculture is therefore assured, and it will be able to begin its labours next year. King Victor Emmanuel has determined that the palace of the institute shall be completely finished by 1907. His Majesty has presented the funds necessary for this enterprise, and the work will be started very shortly.

THE twenty-eighth annual general meeting of the Institute of Chemistry of Great Britain and Ireland was held on March 1, Mr. David Howard, the retiring president, in the chair. In his address, Mr. Howard referred, among other matters, to the great advances in chemistry that had been due to the work of private practitioners, giving his opinion that any action which tends to interfere with the individual practitioners would be fatal to progress. With greater facilities for training, and, consequently, a larger supply of chemists, it was evident that only the most efficient could hope to be successful. In conclusion, Mr. Howard referred to the new president, Prof. Percy F. Frankland, F.R.S., who had long been associated with the institute, and whose father, Sir Edward Frankland, was the founder and first president of the institute.

THE annual meeting of the Liverpool School of Tropical Medicine, which was held last week in the Liverpool Town Hall, under the presidency of the Lord Mayor (Alderman J. Ball), was attended by a large number of prominent citizens, including Sir Alfred Jones (chairman of the school), Mr. William Adamson (vice-chairman of the school), Prof. Carter, Prof. Ronald Ross, C.B., Dr. Caton, Mr. Charles Booth, jun., and Mr. Philip Davey. Princess Christian wrote expressing her constant warm personal interest in the progress of the school, and sympathetic messages were received from other prominent persons. The report shows that excellent work is being done by the school. The committee acknowledges the continued generous support of the public, but further funds are needed in view of the great development of research work. A sympathetic reference was made to the regretted death of Dr. J. E. Dutton, who lost his life while engaged in the investigation of trypanosomiasis and tick fever on the Congo.

AN agricultural conference was held in Bombay on February 5 and following days. In opening the meetings, Mr. Muir MacKenzie, the president, said that important beginnings had been made in the department of agricultural research and education. It was the late Mr. Ozanne who gave the first effective impetus to the scientific development of agriculture in the west of India. He established the Kirkee demonstration farm and dairy. This dairy has developed into an industry which has spread all over India. Referring to the agricultural colleges, the president said that by a course of study at the colleges it was not expected to make a man into a scientific and practical farmer. The colleges give an agricultural bent to the student's mind, and enable him to think correctly about agriculture and to bring to bear upon agricultural problems in India the information thus acquired. Referring to the experiments with Egyptian cotton made in Sind, he said this year the crop was estimated at 1200 bales, and next year 4000 bales were expected. They were justified, he continued, in entertaining some confidence that the establishment of that valuable product in Sind would be an accomplished fact, and would prove a substantial addition to the agricultural resources of the country.

Naturen for February contains an article by Prof. G. Guldberg on the pigmies of the Congo forest.

WE have received a copy of a paper by Mr. C. O. Esterly on the nervous system of copepod crustaceans, issued in the Zoological Publications of the University of California.

AMONG the contents of the February *Zoologist* reference may be made to an article by Mr. G. Renshaw on the extinct Mauritius dove, or "pigeon hollandais" (*Alectoraenas nitidissima*). Discovered between 1774 and 1781, it was still common in 1790, but when it was exterminated

cannot be determined. There is a specimen in the Edinburgh Museum of Science and Art, and another at Port Louis.

To the January number of *Spolia Zeylanica* Dr. O. von Linstow contributes a paper on parasitic worms (Helminthes) in the Colombo Museum, while Mr. N. Annandale discusses certain lizards and stalked barnacles in the same collection. Among the lizards, a curiously striped skink, which had been described as *Euprepes hallianus*, is made the type of the new genus Theconyx. In reference to the recent discovery by Dr. Willey that the lemurs of the genus Loris are almost peculiar among Primates in having four mammæ, Mr. Annandale records that the same condition obtains in their allies of the genus Nycticebus.

According to the annual report for 1905, the Royal Zoological Society of Ireland enjoyed an unusually good year, the gate-money having increased by one hundred pounds, while the entrance-fees and subscriptions reached a total which has only once been exceeded, and then only by a few shillings. The balance-sheet has also benefited to a considerable extent by the sale of superfluous animals. Very wisely, the council has spent a considerable portion of this increased income in improving the accommodation provided for the denizens of the gardens, the most important addition being an open-air aviary measuring 90 feet by 50 feet, with a height of 20 feet. Experiments have also been made, with most satisfactory results, in placing tropical animals in the open air, a number of parrots having been introduced into one of the smaller outdoor aviaries, while a party of Indian rhesus monkeys has likewise been kept for some months without any shelter. An excellent coloured plate, forming the frontispiece to the report, shows these monkeys in the snow, apparently in a high state of health and contentment.

Important information with regard to the origin, rise, and decline of British whaling, both in the icy north and in the southern seas, is furnished by Mr. T. Southwell in the February issue of the *Zoologist* at the conclusion of an article on last season's catch of the Dundee whaling fleet. Although Hull and Bristol had for a long time previously been in the habit of sending vessels to Newfoundland and St. Lawrence Bay for seals and walrus, Greenland whaling was initiated from London and Hull in 1610 or 1611. The Dutch opened the route to Davis Strait in 1719, but were not allowed for long to enjoy the whaling by themselves. Scotland commenced Greenland whaling in 1750 from Leith; Dundee, the only British port from which whalers are now dispatched to the north, not joining in until 1790. Sperm-whaling in the South Seas, which appears to have been confined to the port of London, commenced in 1775 and continued until 1853, when it was abandoned to the Americans. During last season more whales were seen in Davis Strait than for some years past, the total catch being twenty-three.

We have to acknowledge the receipt of four parts (Nos. 1434–7) of the Proceedings of the U.S. National Museum, in the first of which Mr. E. A. Klages describes a collection of moths belonging to a certain group from Venezuela. A fossil raccoon from a cave in California, described by Mr. J. W. Gidley, forms the subject of the second. We regret to see that in describing, in the third, certain macaque monkeys from the Malay countries, Mr. G. S. Miller seeks to replace the well known and universally accepted generic name Macacus by Macaca, on the ground that the latter is the earliest form of the name to be found in scientific literature. We stand sorely in need of a statute of limitation in regard to altering and replacing names. In the fourth Dr. L. Stejneger describes a new species of lizard belonging to the group of "horned toads" from Mexico. Whether, however, this species is entitled to be included under the latter title is almost doubtful, seeing that it lacks the horns from which the others take their name. It is also characterised by a peculiar downward expansion of the lower jaw.

From Dr. F. Ameghino, director of the Buenos Aires Museum, we have received copies of two papers from the *Anales* of that institution, one dealing with the remains of fossil penguins from the Tertiary deposits of Seymour Island, in the Antarctic, and the other with the Tertiary edentate mammals of France and Germany. Judging from their metatarsal bones, some of which indicate birds of very large size, the Seymour Island penguins are represented by a large number of species, these being referred by the author to no less than eight generic types, all of which are regarded as distinct. Of wider interest is the paper on the Oligocene and Miocene edentates of Europe, especially since the author's familiarity with American representatives of the group renders him peculiarly well qualified to test the determination of the European fossils. It is satisfactory to learn that Dr. Ameghino is fully convinced that among the latter are included armadillos, aard-varks, and pangolins, some of the armadillos coming very close to South American forms. This assemblage of three groups of edentates in the countries fringing northern Africa is suggestive that the latter continent may have been the original home of the group, which reached South America by direct land-connection.

The Bausch and Lomb Optical Co., of Rochester, New York, the makers of the Minot microtomes, has recently issued a new catalogue of its instruments, in which reference is made to certain improvements in the Minot automatic rotary microtome.

Under the title "Glycogène et Paraglycogène chez les Végétaux," some notes written by the late Prof. L. Errera are published in the *Recueil de l'Institut botanique*, Brussels, vol. i., 1905. The notes refer to microchemical experiments on certain low organisms to test for the presence of these substances.

The Trinidad Bulletin for January contains articles on cocoa diseases observed in Ceylon and the West Indies, and on the use of lime in agriculture. Two new instruments for rubber-tapping are mentioned, the one a revolving pricking instrument, the other an improved V-cutting knife. Reference is also made to the small fish, species of Girardinus, found in Trinidad and Barbados, that feed on the larvæ of mosquitoes; it is suggested that it would be useful to place them in pools in malarial districts.

The first stage in the inquiry as to the possibility of establishing a beet-sugar industry in this country consists in making cultivation trials in the districts where the industry is likely to be located. Under the superintendence of Mr. G. Clarke, of the County Technical Laboratories, Chelmsford, sugar-beets were grown last year on experimental plots on five different farms. The reports from the growers giving cost and yield per acre are printed, together with the chemical analyses, in a pamphlet published by the Essex Education Committee. The cost of cultivation, manures, and of raising the beets averaged rather more than ten guineas per acre; on a large scale probably eighteen to twenty tons of roots could be grown for about

ten pounds per acre, and it is estimated that the farmer would receive from seventeen to twenty shillings per ton of trimmed roots delivered at the factory.

In a paper read before the Royal Geographical Society on January 29 Prof. G. F. Scott Elliot gave an account of his observations on the various plants that aid in the formation of alluvial flats in the valleys of such rivers as the Aconcagua, in Chile, and the La Plata. The composite shrub, *Baccharis marginalis*, protected from drought by gum-containing leaves, was found to be one of the first settlers to fix the banks on the Aconcagua, after which other plants, including poplars and willows, could secure a hold, and gradually a river-side wood might be formed; or in the deeper backwaters plants of the nature of *Scirpus americanus* or *Juncus dombeyanus*, and in the shallows species of Eleocharis, spread out their horizontally creeping stems and upright stalks holding the mud and catching the drift until, in the marshy condition, grasses could grow over and fill up the swamp.

An experimental station for the study of sugar-cane cultivation and of the diseases of the sugar-cane was opened at Samalkot by the Madras Government in 1902. Mr. C. A. Barber presents a report of the work for the year 1903–4 in Bulletin No. 51 of the Department of Land Records and Agriculture, Madras. Two local varieties, Bonta and Yerra, and an introduced cane, Red Mauritius, were selected for special experiment; the Bonta was eaten out by jackals, the Yerra did not suffer much and gave good results, but the Red Mauritius produced the greatest weight of cane and the largest amount of jaggery. The practice of wrapping the canes that is usual in the Godávari district will form the subject of experiment; the older leaves are twisted and wrapped round bamboos fixed in the ground; the object is two-fold, the leaves serving as a protection against jackals, and the bamboo supports preventing the canes being blown down in cyclonic storms.

A tornado of considerable violence occurred at Meridian, in the State of Mississippi, on the evening of March 2, involving much loss of life and causing great destruction of property. The tornado is said to have travelled at the rate of seventy-seven miles an hour, and to have passed away in two minutes. It apparently travelled from south-west to north-east, and in its progress it is reported to have ploughed a path 600 feet wide and one mile long.

A severe hurricane occurred in the South Pacific on February 7 and 8, and was attended by very serious loss of life and property. According to the report received in this country from San Francisco, received there through the steamship *Mariposa*, damage to the value of 200,000*l*. was wrought in Tahiti, and it is believed that similar damage was caused in the Tuamotu Islands. The loss of life is rumoured as numbering several thousands. Papiete, situate on the north side of Tahiti, is said to have been inundated, and it would appear that the hurricane was accompanied by a series of high waves. The storm is reported to have struck the islands with a wind velocity of 120 miles an hour at midnight on February 7, and to have continued until four o'clock on the following afternoon. In this part of the world storms usually travel from the north-westward. According to the Admiralty sailing directions for the Pacific Islands, the hot months, December to March, are those in which storms may be expected, and clearly they are of fairly common occurrence in the Society Islands and in the Tuamotu Archipelago, but as a rule the hurricanes do not appear to be so severe as those of the Atlantic and Indian Oceans or of the China Seas. At present the information to hand with respect to the recent storm is very meagre, and further details will be anxiously looked for.

Japan has gained her supremacy in the East by a careful and minute study of the methods of the West. It is now the turn of the West to look towards the East for enlightenment, and we do not look in vain. Weather is an important item in commercial prosperity, and the study of it is therefore of the highest importance to every nation. If a country is subject to devastating cyclones, it is of the utmost necessity that inquiry should be set on foot to try to solve the causes of their frequency, and forecast, if possible, their advent, in order to mitigate so far as possible the damaging results which will eventually ensue. One old British possession, a valuable asset to the British Empire, is occasionally visited by these destructive air movements, and instead of concentrating a meteorological attack by erecting a first-class station, the British Government reduces the already microscopic annual grant of 100*l*. to 50*l*. In Japan science is respected, and respected probably because that country knows that scientific method is at the base of progress. In meteorological matters Japan does not mean to be left behind, and as the first duty of a German colonist seems to be to set up a barometer and thermometer and read them, so Japan follows suit by organising a meteorological service in Korea and Manchuria. An article upon this service, and the first-class observatory at Chemulpo, appeared in the *U.S. Monthly Weather Review* for September, 1905, and has already been noticed in these columns (February 15, p. 374).

A conspicuous and valuable feature of recent numbers of the Proceedings of the Tokyo Physico-mathematical Society is the number of short papers containing simple applications of deductive reasoning to physical phenomena. Thus we have an extension of Gibbs's phase rule to systems in which the potential differences between the phases enter into the equations, by Shizuwo Sano (ii., 25); a theory of the rainbow due to a circular source of light, by K. Aichi and T. Tanakadate (ii., 27); a discussion of the whistle produced by the vibration of a liquid drop, by T. Terada (ii., 26); and an explanation of the existence of secondary vibrations in seismic waves, by H. Nagaoka (ii., 28), based on the supposition that the acceleration due to the elastic force of the rock contains terms proportional to powers of the displacement higher than the first.

"A Problem in Analytic Geometry with a Moral" is the somewhat attractive title of a paper by Prof. Maxime Bôcher in the *Annals of Mathematics*, vii., 1. The problem, which is quite elementary, consists in the determination of all the families of conics which cut a given conic, say $x^2 - y^2 = 1$, at right angles. Taking the intersecting conic as given by the general equation of the second degree, the method of solution is to find the locus of the points the polars of which with respect to the two conics are at right angles, and to make this locus pass through the intersection of the two conics. At this stage the author advises the reader to complete the solution himself before reading further; if he does so, there is considerable probability that he will fail to obtain all the four solutions. The reason of this is that there is one family of orthogonal conics such that the polars of *any* point with respect to one of these conics and the original conic are at right angles, so that the coefficients in the equation of this locus vanish identically. The interesting point is that these conditions determine, not a single curve, but a family of curves with the same degree of generality as the families determined by the other conditions.

A NUMBER of papers on aërial navigation have appeared comparatively recently. Of Captain Ferber's work on stability of aëroplanes mention has been already made (p. 350), and it may be sufficient to add that in this particular connection, contrary to the old adage, "an ounce of theory is worth a pound of practice." But the same writer has since sent us a reprint of papers in the *Revue d'Artillerie* for August last, now published by Berger-Levrault, of Paris, under the title "Pas à Pas, Saut à Saut, Vol à Vol," which, to emulate the author's style, constitutes a comprehensive *vol au vent* of experimental gliding up to date, illustrated by many figures. Turning a little further back to the *Revue scientifique* (5, iii., 24, 25), we find an interesting discussion by M. Bazin of the source of energy in sailing flight of birds. The theory is essentially identical with that brought into prominence by Langley's work, in which variations in wind-velocity account for the phenomenon; but the author has also shown how models can be constructed in which this explanation is illustrated by the motion of a marble rolling on a movable kind of switchback. More recently, in the *Revue générale des Sciences* (xvi., 21), M. M. Léger details his attempts at obtaining the necessary lifting force in a machine of the "plus lourd" type by a combination of "helicopters" (vertical screws) and aëroplanes; his experiments have been carried out with the assistance of the Prince of Monaco. A little further back in the same series Lieut.-Colonel G. Espitallier discusses the materials and construction of balloons. Prof. S. P. Langley's work is described in a pamphlet, reprinted from the Smithsonian report by the Washington Government. A paper has also reached us from Madrid detailing the formation of a Royal Aéreo-Club of Spain. The current numbers of the *Aëronautical Journal* contain too much matter to be summarised here. Attention should, however, be directed to the flying model competition organised by the Aëronautical Society for July of this year.

A COPY of the twenty-sixth volume of the Proceedings of the Dorset Natural History and Antiquarian Field Club has been received. The volume has been edited by Mr. W. Miles Barnes. It contains the presidential address of Mr. Nelson M. Richardson, and, in addition to other contributions, papers by the Rev. O. Pickard-Cambridge, F.R.S., on new and rare British Arachnida; the Rev. E. F. Linton, on Dorset plants; Mr. H. Stillwell, on the returns of rainfall in Dorset; the Rev. H. S. Solly, on the landslip at Lyme Regis; Mr. W. B. Barrett, on the flora of the Chesil Bank and the Fleet; and the president, on first appearances in 1904 of birds, insects, and first flowering plants in Dorset.

OUR ASTRONOMICAL COLUMN.

DISCOVERY OF A NEW COMET, 1906*b*.—A telegram from the Kiel Centralstelle announces the discovery of a new comet by Herr Kopff at the Königstuhl Observatory on March 3.

At 14h. 52·8m. (Königstuhl M.T.) on the day of discovery the position of the comet was

R.A. = 11h. 35m. 56s., dec. = + 1° 40′,

and the following values were determined for the daily movement:—in R.A. −7′ (−28s.), in dec. +4′.

A second telegram from Kiel announces that Dr. Valentiner, observing at the Königstuhl Observatory, Heidelberg, on March 4, recorded the position of this object as

R.A. = 11h. 35m. 35·8s., dec. + 1° 40′ 37″

at 10h. 13·4m. (Königstuhl M.T.).

Thus it will be seen that the comet is in the southern part of the constellation Leo, and was about half-way between ν Leonis and β Virginis when discovered. It is travelling very slowly in a W.N.W. direction, and is on the meridian about midnight. No intimation of its magnitude has, as yet, been received.

THE RING NEBULA IN LYRA.—In 1902 Dr. Newkirk showed, in his inaugural dissertation for the doctor's degree at Munich, that the central star in the annular nebula in Lyra had a proper motion, and, from the value he obtained for this movement, he deduced the parallax of the nebula, finding it to be 0″·10.

As this was the first nebula for which any proper motion and parallax had been deduced, the verification of Dr. Newkirk's results became a matter of great importance, and therefore Prof. E. E. Barnard has made several measurements, photographic and visual, with the 40-inch refractor at Yerkes Observatory.

The results obtained do not verify those of Dr. Newkirk. According to the latter the total displacement of the nucleus during the five years which elapsed between Prof. Barnard's observations in 1898–9 and those of 1903–4 would have amounted to 0″·90, an easily measurable quantity, but no displacement at all could be detected.

As Dr. Newkirk's parallax for the central star depended upon his value for the proper motion, it must now, according to Prof. Barnard's results, be rejected as fallacious.

The latter observer concludes from his observations that everything in the immediate region of this nebula seems to have the usual fixity of the ordinary small stars (Monthly Notices R.A.S., vol. lxvi., No. 3).

A CLUSTER OF NEBULÆ IN PERSEUS.—In No. 4069 of the *Astronomische Nachrichten* Dr. Max Wolf describes his discovery of a number of small nebulæ in the regions about β and Nova Persei. These objects were seen, and their positions measured, on photographs obtained with the Bruce telescope, and they mostly lie in two bands, for which Prof. Wolf gives the positions.

The nebulæ are especially dense where these two bands coalesce, a region of 12′ (of arc) square containing 148 of them. Their forms are generally recorded as "round, with central condensation," and "form of Andromeda nebula."

TWENTY-FIVE NEW VARIABLE STARS.—Circular No. 107 of the Harvard College Observatory contains the positions and magnitudes of twenty-five variable stars recently discovered by Miss Leavitt from the examination of six plates taken with the 24-inch Bruce telescope.

The plates are of fine quality, and probably show altogether some 200,000 star images. The twenty-five variables contained in the list lie in the constellations Orion, Virgo, and Cygnus, and two of them in the last named constellation have magnitude ranges of 3·5 and 3·0 respectively.

THE GLOW SURROUNDING THE LUNAR CRATER LINNÉ.—Some interesting results of observations of Linné are published by Prof. E. E. Barnard in No. 4075 of the *Astronomische Nachrichten*.

The glow surrounding the crater was measured, on various dates between December, 1902, and November, 1904, with a micrometer attached to the 40-inch refractor at Yerkes, and Prof. Barnard concludes that its diameter does vary with the moon's age. The following table represents the curve, obtained from the observational results, for the varying diameters:—

Moon's age d. h.	Diam. of glow ″	Moon's age d. h.	Diam. of glow ″
7 0	6·6	14 0	3·4
8 0	6·0	15 0	3·3
9 0	5·4	16 0	3·3
10 0	4·8	17 0	3·4
11 0	4·3	18 0	3·5
12 0	4·0	19 0	3·8
13 0	3·7		

The diameters have been reduced to the moon's distance on January 12, 1903, viz. 221,820 miles. Whilst not certain of the exact form of the curve after full moon, Prof. Barnard thinks there is no doubt that it rises.

Two measures of the crater itself gave a mean of 0″·63 when reduced to the above distance. This corresponds to an actual diameter of about 3600 feet. Other interesting details of the crater and the glow are given in Prof. Barnard's notes.

THE VERTICAL DISTRIBUTION OF THE METEOROLOGICAL ELEMENTS ABOVE THE ATLANTIC.

In a previous article (vol. lxxiii. pp. 54–56) we described our expedition to the tropics, and gave the results of the observations with balloons and on mountains, so far as they related to the movements of the upper currents. In the present article we will consider the observations with kites, which furnished nearly continuous records of temperature, humidity, and wind velocity from sea-level to a height of 2300 metres, and the direct observations to a greater height which Mr. Clayton obtained in ascending and descending the tropical peaks on the islands of Teneriffe and Fogo. During a voyage of the White Star steamer *Romanic*, from Boston to Gibraltar, Mr. Clayton executed six kite-flights, and on board the steam-yacht *Otaria*, between latitudes 37° and 10° N., longitudes 16° and 31° W., with the assistance of M. Maurice, seventeen kite-flights were made, besides two in the harbour of Santa Cruz to investigate the sea breeze, and one in latitude 43° 43′ N., longitude 8° 43′ W., for the study of the changes in the free air produced by the total solar eclipse. The observations obtained at the height of 1000 metres, compared with those at sea-level, are given in Tables i. and ii. The first table contains the observations made in a general east and west direction between longitudes 69° and 16° W., latitudes 42° and 33° N. West of the Azores, that is to say, on the westward slope of the permanent area of high pressure, the decrease of temperature with height was slow, there being two cases out of the four in which the temperature increased immediately above the ocean, the average decrease in the thousand metres being but 0°·41 C. On the eastern and southern slopes of the high pressure the temperature decrease approached the adiabatic rate, amounting on the average to 0°·73 C. per hundred metres. The relative humidity diminished with altitude over the western barometric slope and increased in the observations obtained over the eastern slope, while the wind veered and increased with altitude in the former locality and backed with diminishing velocity in the latter. Fig. 1 shows the typical vertical distribution of the meteorological elements to the westward of the Azores.

The observations made at the height of 1000 metres and at sea-level in a general north and south direction, between latitudes 35° and 10° N., appear in Table ii. It will be seen that the temperature decrease is most rapid (average 0°·78 C. per 100 metres) near the northern and southern limits of the north-east trades, and is least rapid within the trade-wind region (average 0°·07 C.), due to the presence of strata with inverted temperature gradients, of which a typical example, with the corresponding changes of humidity, is shown in Fig. 2. The relative humidity varies inversely with the temperature, being slightly greater at 1000 metres just outside the trade wind, and much less at this height within the trade belt. While the observations of wind do not indicate any marked deviation from the north-easterly direction, there is a considerable decrease in the velocity of the trade with increasing height.

Mr. Clayton's study of the data collected in the tropics points to the existence of three strata between the sea and 4000 metres, characterised by differences in tempera-

* Peak of Teneriffe. † Peak of Fogo.

ture, humidity, cloudiness, and wind. The trade wind, limited to about 1000 metres in thickness, varies in direction between north and east, is damp, and usually carries cumulus or strato-cumulus clouds in its upper portion. Above the surface trade is a current about 2000 metres in depth, varying in direction between north-east and north-west, but coming always from a direction to the left of the lower wind when facing it. This current is extremely dry and potentially warm, and its velocity is usually much greater than that of the lower wind. At their plane of meeting occurs a belt of calms or light winds with a marked inversion of temperature, and this rise of temperature is

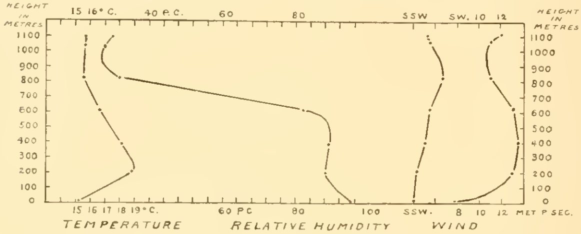

FIG. 1.—Vertical Distribution of Temperature, Humidity and Wind, June 6, 1905; Lat. 40° 33′ N., Long. 46° 43′ W.

accompanied by a very decided fall of humidity, the relative humidity in some cases falling to nearly zero. The third stratum, which begins at a height of about 3000 metres, moves from a direction varying between east and south or south-west, being generally from the east in equatorial regions and from the south between latitudes 15° and 30° N. As observed on the Peak of Teneriffe, this stratum was dry in its lower portion, but had a slightly larger vapour contents than the air immediately below. Alto-cumulus and alto-stratus clouds were seen floating in it at a height of perhaps 4000 metres or 5000 metres, and from them light sprinkles of rain fell occasionally. In passing into this upper current a rise of temperature was noted, but this was less marked than

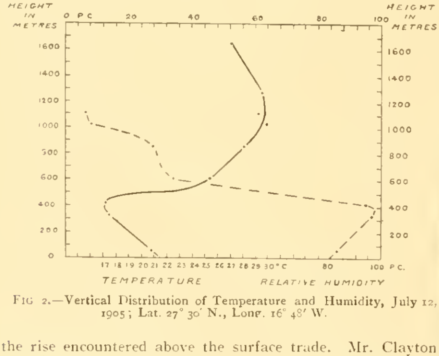

FIG 2.—Vertical Distribution of Temperature and Humidity, July 12, 1905; Lat. 27° 30′ N., Long. 16° 48′ W.

the rise encountered above the surface trade. Mr. Clayton also deduces the following facts from the observations:—(1) the bases of the cumulus clouds are low over the ocean, rarely exceeding 500 metres; (2) the height of the inverted temperature gradient varies from day to day between 300 metres and 1500 metres, with a probable average of 1000 metres, and its height also appears to undergo a diurnal change, being lowest at night or in the morning and highest in the afternoon; (3) the adiabatic rate of decrease of temperature prevails over the ocean at night as well as during the day.

The vertical distribution of temperature and humidity revealed by our observations up to a height of 4000 metres agrees in general with that found by Prof. Hergesell during the cruises of the Prince of Monaco's yacht in 1904 and 1905 (see *Comptes rendus de l'Académie des Sciences*, January 30, 1905, and *Bulletin du Musée Océanographique de Monaco*, November 30, 1905). From the latter publication it is interesting to learn that a balloon, liberated by Prof. Hergesell on August 7 last far to the westward of the Canary Islands, indicated the same currents which were found by us in the neighbourhood of these islands, since it met the south-east and south-west winds above the north-east trade. It is significant that this balloon reached a greater height than did the other balloons, which showed winds having a northerly component. We perceive that Prof. Hergesell no longer denies the possibility of an upper anti-trade in a lower latitude than the Canaries, but now simply states that in the central part of the Atlantic he found almost exclusively north-west winds, from which he concludes that the route followed by the currents bringing the air from the equator appears to be less simple than had been supposed, and seems to depend on the relative positions of the continents and oceans. The study of the daily isobars over the ocean, which was first made under the direction of Le Verrier in 1864, showed that the pressure is not distributed in uniform belts, and that the isobars are everywhere deflected by the influence of temperature distribution dependent upon the land and sea, relations which were demonstrated by M. Teisserenc de Bort's study of isonormals more than twenty years ago. Hence it would appear that there are certain regions where the anti-trade is more regular than elsewhere, the zone between the Cape Verde and Canary Islands being no doubt one of these; but this view is quite contrary to the idea that the south-east and south-west winds observed in the upper atmosphere near these islands, and hitherto accepted as proof of the anti-trade, are due to local influences, which Prof. Hergesell still affirms to be true.

A. L. ROTCH.
L. TEISSERENC DE BORT.

THE TRANSFORMATIONS OF ROCK-MASSES.[1]

THE study of the changes which rock-masses undergo under natural conditions is in itself by no means an inconsiderable branch of geology, and its pervading importance throughout the whole field of the science brings it continually to the front in stratigraphical as well as petrological research. The literature of the subject is a large one, but until now no serious attempt has been made to deal fully and comprehensively with the principles and phenomena of metamorphism as a whole. Prof. van Hise's wide experience in the Lake Superior region and elsewhere has made him well fitted for a task to which he has devoted seven years of labour; and the outcome of that labour, as represented in the massive volume before us, will have a permanent value for all who come after him in this field.

This treatise, as we are told in the preface, is "an attempt to reduce the phenomena of metamorphism to order under the principles of physics and chemistry, or, more simply, under the laws of energy." Metamorphism is understood to include all alterations of all rocks by all processes. This extension of customary usage may be defended on logical grounds, and it has the advantage of constantly keeping in view the essential unity underlying the complex operations of nature; but it involves a corresponding enlargement of the subject-matter. The scrupulous—almost relentless—manner in which the author follows out in every detail the general scheme of treatment laid down further swells the bulk of the volume, and, brought out in the handsome style which characterises the produc-

1 "A Treatise on Metamorphism." By Charles Richard van Hise. (Monographs of the U.S. Geological Survey, vol. xlvii.) Pp. 1286 and 13 plates. (Washington, 1904.)

tions of the Survey, it is physically not an easy book to handle.

In the first chapter a general discussion leads to the conclusion that the most important factor in metamorphism is the depth of the rocks below the surface. In the upper zone of the earth's crust the chemical changes are such as result in the production of simpler compounds from more complex ones, while in the deeper part the reverse is the case. The starting point of the author's treatment is this antithesis between the upper zone of *catamorphism* and the lower zone of *anamorphism*. It appears to us that, while the broad rule here laid down is doubtless of significance, it has scarcely sufficient precision to serve as a basis of classification. The productions of muscovite from orthoclase, and of natrolite from albite, are, according to this geological distinction, catamorphic changes, but it cannot be said that they result in the formation of simpler from more complex compounds.

The second chapter deals with the forces of metamorphism, and the third with the agents of metamorphism, *i.e.* especially gaseous and aqueous solutions. This involves a *résumé* of the principles of physical chemistry, so far as they are applicable to the subject. Although somewhat handicapped by the author's scepticism concerning the doctrine of electrolytic dissociation, this summary will be very useful to students of geology. Chapter iv. treats of the characteristics of the two zones of metamorphism. The law is found to be that in the zone of catamorphism the alterations are attended by liberation of heat and expansion of volume; in the zone of anamorphism by absorption of heat and diminution of volume. The zone of catamorphism is divided into the belt of weathering, lying above the level of underground water, and the belt of cementation, lying below that level; and the geological processes characteristic of these two belts are contrasted.

Chapter v., which might perhaps have been abridged without impairing the value of the book, considers the actual alterations undergone in nature by each of the rock-forming minerals. The chemical reactions are illustrated by equations, and the percentage increase or decrease of volume is calculated in each case. The precise application of these calculations is perhaps debatable, since special assumptions have to be made regarding such gaseous and soluble substances as take part in the reactions, and in some cases the equations themselves are rather conjectural. The next three chapters are an analysis of the processes of change in the belt of weathering, the belt of cementation, and the zone of anamorphism respectively. Under the last head the most important discussion is that relative to secondary gneissic and schistose structures. The author concludes that "Rock-flow is mainly accomplished through continuous solution and deposition, that is, by re-crystallisation of the rocks through the agency of the contained water. But rock-flow is partly accomplished by direct mechanical strains." The ninth chapter deals with the phenomena of metamorphism of individual rocks, and with this the systematic treatment of the subject ends; but there remain some interesting chapters applying the principles enunciated in this treatment to certain other branches of geology.

Chapter x. discusses the difficulties which metamorphism often introduces into stratigraphical investigation and the manner in which these difficulties may be overcome. The next chapter, which is the most novel part of the book, has for its subject the relations of metamorphism to the distribution of the chemical elements. It is shown that, as compared with the parent igneous rock-masses, most sedimentary rocks become impoverished in certain elements, which are thus segregated in particular deposits. Some of the numerical results are of a surprising kind. Thus, it is calculated that to oxidise the ferrous iron of the original rocks to the ferric state, in which most of it occurs in the sediments, required 35 per cent. of the oxygen now in the atmosphere. To oxidise the sulphur and iron of iron-sulphides to produce the sulphates of the ocean and gypsum deposits, with concurrent transformation of the iron to the ferric form, required one and a half times the oxygen now in the atmosphere. The final chapter, occupying no less than 240 pages, might perhaps have been deemed sufficiently complete in itself for separate publication. It is practically a treatise on the principles of ore-deposition. The subject is one upon which much divergence of opinion is still found. Prof. van Hise, as is well known from his former writings, has devoted long study to it, and the complete exposition which he now offers will be read with general interest. From his point of view, the majority of ore-deposits have been produced by metamorphism, in the broad sense of the term already defined, and it results that the theory of their genesis consists mainly in bringing the phenomena which they exhibit under the general principles of metamorphism. The conclusion is reached that in many cases the ores have resulted from repeated segregations of the kind considered in the preceding chapter.

FIG. 1.—Fairview Dome, Sierra Nevada, from the north; illustrating the manner in which granite scales parallel to the periphery as a result of expansion and contraction due to changes of temperature.

It is impossible to study Prof. van Hise's work without admiring the boldness of his design and the skill with which it is carried out, and being grateful for the stores of carefully arranged information which he has brought together. We must readily admit, too, that he has done good service in insisting upon the necessity for the geologist to familiarise himself with the recent progress of physical chemistry, a knowledge of which, as van 't Hoff and others have shown, is a pre-requisite for attacking many of the most pressing problems of geology. Granting this, however, we may still be permitted to doubt whether a purely geological subject like metamorphism is most advantageously dealt with in the manner which is appropriate to the exact sciences. In such a formal schematic treatment there is some danger of making it appear that our knowledge of metamorphism is to be deduced from chemical principles instead of depending upon observation. Although the criticism would not be a just one in the present case, we venture to express a wish that the author had chosen to describe the facts first and explain them afterwards, and that he had made freer reference to actual rocks and specified localities.

A. H.

A NEW OXIDE OF CARBON.

THE current number of the *Berichte der deutschen chemischen Gesellschaft* (1906, xxxix., p. 689) contains a preliminary communication by Messrs. Otto Diels and Bertram Wolf, of the Berlin University, giving an account of the preparation and properties of a new oxide of carbon having the composition C_3O_2, for which they propose the name *carbon suboxide*. The new oxide is obtained from ethyl malonate, $CH_2(CO_2C_2H_5)_2$, by subjecting the vapour of the latter to the action of phosphorus pentoxide at 300°; under these conditions two molecules of water are removed by the action of the latter reagent, and a mixture of ethylene and carbon suboxide formed, the reaction being expressed by the equation

$$CH_2(CO_2C_2H_5)_2 = 2C_2H_4 + 2H_2O + C_3O_2.$$

The ethylene and carbon suboxide are condensed together in a receiver cooled with liquid air, and subsequently separated by fractional distillation.

Carbon suboxide is a gas at the ordinary temperature, which burns in the air with a smoky flame, has a most penetrating smell, resembling that of acroleïn and mustard oil, and attacks the eyes, nose, and respiratory organs violently. On cooling it condenses to a colourless, highly refractive liquid, which boils at 7° under 761 mm. pressure. The results of the analysis and of the determination of the vapour density show that the molecular formula is C_3O_2.

Carbon suboxide at once combines with water, re-forming malonic acid, and also unites with ammonia, hydrogen chloride, and aniline, forming malonamide, malonyl chloride, and malonanilide respectively; it therefore contains the chain of carbon atoms previously existing in the malonic acid derivative from which it is prepared, and in all probability possesses the constitution represented by the formula OC : C : CO. Hence in both its constitution and properties it has a close analogy with the metallic carbonyl derivatives, and especially with Mond, Langer, and Quincke's nickel tetracarbonyl, $Ni(CO)_4$.

When the liquid suboxide is sealed in glass tubes it slowly undergoes change at the ordinary temperature, and is finally converted into a dark red solid, which dissolves in cold water, yielding an intense eosin-red solution. At higher temperatures the alteration takes place much more rapidly, and the product is then no longer completely soluble in water. The nature of the changes here taking place is still under investigation.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—One hundred and fifty-five students have entered for the First Part of the natural sciences tripos and twenty-five for the Second Part in the coming June. In the mechanical sciences tripos there are fifty candidates. These figures show a considerable increase in the numbers for the last few years. There are seventy-seven in for the First Part of the mathematical tripos, and seven entered for the Second Part.

The Vice-Chancellor has announced that the Girdlers' Company has offered to renew, for a further period of three years, its grant of 100*l.* a year towards the study of economics in Cambridge.

The General Board of Studies has approved for the degree of doctor in science Mr. F. W. Keeble, Gonville and Caius College.

The Special Board for Physics and Chemistry has agreed to expend its share of the Gordon Wigan Fund as follows:—(1) A sum of 50*l.* per annum is to be granted to the department of chemistry for five years for the establishment of a prize or otherwise for the encouragement of research in chemistry. (2) The balance of the income is to be used for the assistance of research and teaching amongst the departments of the University directly connected with the Board, other than that of chemistry, it being understood that on the average the departments should share equally. (3) Applications for grants are to be made by the heads of departments and be considered at a meeting of the Special Board held not later than the division of the Michaelmas term in each year. Grants not exceeding 74*l.* have been made out of the balance on income account for 1905 to the departments of physics and mineralogy to defray the cost of special apparatus.

IT is reported from Berlin that Mr. Alfred Beit has presented 100,000*l.* to Hamburg for the establishment of a university.

THE Goldsmiths' Company has made a grant of 1000*l.* to the building and endowment scheme for Bedford College, University of London. The Grocers' Company has granted 25*l.* for the same purpose.

THE Goldsmiths' Company has made a grant of 10,000*l.* to the Institute of Medical Sciences Fund, University of London, on the assumption that a site will be provided for the institute at South Kensington.

PRESIDENT THOMAS, of Bryn Mawr College, has announced, says *Science*, a gift of 16,000*l.* from Mr. John D. Rockefeller, to enable the college to meet the expenses incurred by the trustees over and above the gift of 50,000*l.* in 1902 for the new library. Mr. Rockefeller has contributed in all 91,000*l.* to the college. From the same source we learn that McGill University will receive 10,000*l.* from the estate of the late Mr. Edwin H. King, former general manager of the Bank of Montreal.

MR. F. C. FORTH, principal of the Municipal Technical Institute, and director of technical instruction for Belfast, has compiled a very useful "Student's Guide to Prizes and Scholarships." The guide is primarily intended for the information of present and future students of the institute over which the compiler presides, but, as it contains details of scholarships at universities and other institutions of higher education, it should appeal to a wide circle of students elsewhere. The guide demonstrates in a convincing manner the numerous facilities in existence to assist earnest students of slender means to continue their education so far as their abilities allow.

MR. WYNDHAM, M.P., delivered an address at the distribution, on March 3, of prizes won by the students of the Dover municipal schools of science, art, and technology. He said the study of science is the study of truth. The pursuit of science is not beset by those pitfalls which are now called "terminological inexactitudes." In science, if the cause is known the effect can be foretold; it is the only safe form of prophecy. The pursuit of pure science is the noblest calling to which earnest endeavours can be given. The present age is preeminently the age of science, and all who study it feel they are comrades in the great quest for truth. The pursuit of science has brought in its train gifts of various kinds, and to the worker in technology it has brought perhaps the greatest gift that anyone can obtain—the gift of independence, not only pecuniary independence, but the gift to men and women of an ample field for their own energy in which they can win distinction, and at any rate justify their existence upon earth.

ON February 28, in the presence of a large and representative gathering of agriculturists, representatives of county councils, the Scotch Education Department, and others interested in agricultural education, Lord Balfour of Burleigh formally opened the new buildings of the Edinburgh and East of Scotland College of Agriculture. The new buildings, situate in George Square, Edinburgh, consist of well equipped chemical, botanical, and bacteriological laboratories and lecture-rooms, and class-rooms for the various other subjects which form part of the college course. Adequate provision is also made for the staff of lecturers engaged in extension work in the counties. The cost of the present scheme has amounted to more than 9000*l.*, and has been almost entirely met by grants from the Scotch Education Department, the Carnegie Trust, the Highland and Agricultural Society, and subscriptions from landowners and farmers. In the course of an interesting address, Lord Balfour referred with satisfaction to the improved relations which now exist between the farmer and those engaged in the work of agricultural education and in the application of the various sciences to the investigation of agricultural problems.

THE Education Committee of the London County Council has issued a report, drawn up by a subcommittee, dealing with the question of apprenticeship. A carefully thought out scheme of scholarships for particular cases is, the report states, the only effective, as well as the only legal, substitute for the old-fashioned apprenticeship premium within the reach of a local authority. The report shows that there are in London various apprenticeship charities with an aggregate income of 24,000*l*. a year, and not more than one-third of this sum has been expended in the payment of premiums. It is suggested that these funds might with advantage be devoted to technical scholarships for poorer children in higher elementary schools, or to the maintenance of boys while they are attending day technical instruction, and thus unable to earn wages. Attention is directed in the report to the lack of technical training in London, and the subcommittee urges that if the apprenticeship system is destined to disappear, it is necessary to find a substitute for such training. Scholarships tenable at evening classes, industrial scholarships at day technical classes, and at trade schools, and the part-time system by which the boy or girl spends a portion of the day in the workshop and the remainder in a day technical school, are mentioned as ways of training which will take the place of the old indentured apprenticeships.

THE scheme of training urged upon the London County Council by its Education Committee as a substitute for the apprenticeship may be summarised briefly as follows:—The intelligent boy, as he leaves the elementary school, will have offered him the choice of two courses of instruction which will assure him an all-round training in a skilled trade. There will be, first, the "part-time" system, in which he will spend a portion of the week in the workshops and the remainder in the day technical school, and, secondly, there will be evening classes. In certain cases scholarships carrying free tuition and a maintenance grant will be awarded to the day students to compensate for the small earnings received during the years of training. Other scholarships of less value will be allowed to some of the evening students in order to encourage regularity of attendance. From this class of student will be drawn the skilled worker of the future. The boy, as he leaves the higher elementary school, will be able to enter the day trade school, either by paying the fees himself or by winning one of the trade scholarships. With this stream of boys coming from the higher elementary school will mingle another stream of boys who, having completed their course at the secondary school, have competed for one of the trade scholarships. From this class of student will be drawn the future foremen and managers of industrial undertakings. Finally, a development of the senior County Council scholarships will make it possible, not only for intermediate scholars, but also for certain of the holders of trade scholarships, to proceed, for the highest technological instruction in the engineering, electrical, chemical, or other industries, to the university. From these will be drawn, we may hope, the future inventor, the future managers of large businesses, and the future "captains of industry." A somewhat less elaborate system will afford similar facilities for girls.

THE science laboratories and class-rooms at Dulwich College have long been inadequate for the demands made on them. The governors of the school, with their chairman, Lord Davey, have now, owing to the cooperation of the Estates Governors with the Charity Commissioners and the Board of Education, been able to commence the building of a new science school, the foundation-stone of which was laid with due ceremony on Saturday last by Lord Rayleigh, P.R.S. The school is to consist of two floors, the upper for chemistry, providing an advanced laboratory, a large combined lecture-room and laboratory, a junior laboratory, a separate lecture-room with preparation store, and balance rooms; the lower for physical science, and containing a senior and junior laboratory, two lecture-rooms, and a school museum. Provision is also made for a master's room, a photographic dark-room, and a small workshop. The building is being erected from the plans of the school architect, Mr. C. E. Barry. In his speech in the great hall Lord Rayleigh contrasted the old and present position of science in schools. He pointed out that scientific spirit and method should be the aim of the teaching. In the present-day provision of elaborate apparatus and fittings things were in danger of being made too mechanical. He mentioned the simple apparatus used by Maxwell, and by Hughes for the microphone, who carried simplicity almost to an absurdity. The charms of accurate measurement were briefly touched upon. He thought there was also a tendency to try and cover too much ground in science teaching at schools; less, more thoroughly done, would be better. His own classical education was not literary enough; he was taught no English composition. Modern languages would be better than Greek for very many boys.

THE London Inter-collegiate Scholarships Board was constituted in 1904 with the approval of the governing bodies of University College, King's College, and the East London College, for the purpose of holding a combined annual examination for entrance scholarships and exhibitions tenable at those colleges. One examination has been held already, and with satisfactory results. The next examination will take place in London on May 15 and following days. The competition is limited to those who have not previously been students at any one of the colleges, except where the contrary is stated. No candidate will be admitted to the examination unless he has passed the matriculation examination of the London University, or any examination accepted by the University in lieu thereof, or is the holder of a school leaving certificate, or is able to furnish some evidence of having had a sound general education which is satisfactory to the Board. Application should be made to the secretary of the Board, University College, London, Gower Street, W.C., for forms of entry, which must be returned not later than May 1. Any scheme tending to diminish the number of examinations to which pupils in secondary schools are subjected is to be welcomed, and we trust that the schoolmasters of London will appreciate the efforts of this Board. The insistence upon the possession of a good general secondary education by the holders of scholarships at the group of colleges concerned is a step in the right direction, and it is to be hoped this example will be copied by similar institutions throughout the country.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 2, 1905.—"On the Electr Resistance to the Motion of a Charged Conducting Sphere in Free Space or in a Field of Force." By G. W. **Walker.** Communicated by Prof. A. E. H. Love, F.R.S.

November 16, 1905.—"First Photographs of the Canals of Mars." By Prof. Percival **Lowell,** Flagstaff Observatory, Arizona. Communicated by Sir Norman Lockyer, K.C.B., F.R.S.

With this paper the author communicates a number of photographs which undeniably prove the objective reality of the Martian canals. From a large number of photographs obtained by Mr. Lampland during May and June, 1905, five have been selected for publication, and when these are studied with the contemporaneous, yet quite independent, drawings made by Prof. Lowell, the more prominent canaliform features on the Martian disc are plainly seen.

The photographs show, so far as the grain of the photographic plate permits, that the canals are narrow and direct lines following arcs of great circles or curving in a systematic manner. There is evidence, although for the present the author does not care to assert it definitely, that both a *double* canal and a *double* oasis have been photographed.

One remarkable result that has accrued from Mr. Lampland's researches is the increased efficiency to be obtained by diaphragming down the objective, so that its effective aperture becomes equal to, or less than, the length of the atmospheric waves obtaining at the moment of observation. If the aperture is so large that more than one such wave is in front of the objective at the moment of exposure, poor definition results, caused by the consequent quiver in the rays from the planet; but if only one wave be included, the atmospheric displacement of all the rays is homogeneous, and good definition results.

In obtaining the photographs a colour screen and Cramer isochromatic plates were employed, and the camera was made movable so that numerous successive photographs might be obtained on the same plate, thereby greatly increasing the chance of obtaining at least one well defined photograph at each observation. About 700 images of the planet were secured in this way during the short time that it was favourably placed for such work during the opposition of 1905.

December 7, 1905.—"On Mathematical Concepts of the Material World." By Dr. A. N. **Whitehead,** F.R.S.

January 25.—"Galvanic Cells produced by the Action of Light.—The Chemical Statics and Dynamics of Reversible and Irreversible Systems under the Influence of Light." (Second Communication.) By Dr. Meyer **Wilderman.** Communicated by Dr. Ludwig Mond, F.R.S.

February 15.—"The Chemical Constitution of Protoplasm as shown by the Rate of Tissue Disintegration." By Dr. H. M. **Vernon.**

If a kidney be perfused with saline solution for five to eight days, it is found that from 28 per cent. to 60 per cent. of the tissues pass into solution. These constituents consist of proteid and proteid disintegration products, and contain a good deal of the peptone-splitting ferment erepsin. Sometimes the passage of the kidney tissue from life to death is quite gradual, with no accompanying disintegration. At other times it takes place suddenly, and the proteid and ferment washed out of the kidney may very quickly increase four- to twenty-fold, and then dwindle away again. Sudden and very marked disintegration is invariably produced by adding ether or chloroform to the perfusion liquid. Sudden death produced by perfusion with NaF does not lead to any sudden disintegration. The rate of disintegration is extremely responsive to changes in the perfusion liquid, *e.g.* substitution of 1 per cent. saline for 4 per cent. saline caused a thirty- to sixty-fold increase in the disintegration both of ferment and proteid groups. On the other hand, if already perfused saline were sent through the kidney a second time, the proteid disintegration might be *diminished* to a seventh its previous value, but the ferment disintegration *increased* even twenty-fold.

After the first few hours' perfusion, a roughly constant amount of nitrogen continues to break away from the tissues in a non-proteid form, though the proteid breaking away at the time may vary as 1 to 1300. It is produced by autolysis. Almost the whole of the nitrogen is present in the tissues as potential proteid, and may be made to break off as actual proteid; but if the kidney be perfused with saline containing 0·1 per cent. of lactic acid—which has no action on ordinary proteid—more than half the unstable potential proteid of the tissues is split up.

These results seem to indicate that the difference between living and dead tissues is one of degree rather than of kind, for the dead tissues show great lability, and their self-decomposition is greatly augmented by stimuli.

Anthropological Institute, February 13.—Prof. W. Gowland, president, in the chair.—Two clay images used by the A-Kikuyu of British East Africa in harvest ceremonies, and a slide showing four remarkable dance armlets used by the natives on these occasions: **Secretary.** The images were about 9 inches in height, and were very rude representations of the human figure; they appear to be greatly venerated by the natives; the two specimens shown were, so far as is known, the only ones that have reached Europe.—Selection of slides showing rude stone monuments in Glamorganshire: A. L. **Lewis.** The author described the monuments at Tinkinswood, near Cardiff, the fine cromlech at St. Lythian's which bears close resemblance to that at Kit's Coty House. At Pontypridd there is a curious group of stones consisting of a rocking stone, surrounded by two circles and two small curved avenues forming the head and tail of a serpent. This group has been considered by many to be ancient, and ingenious theories have been woven round it, but Mr. Lewis was able to prove conclusively that the stones had not been in position for very much longer than fifty years. Mr. Lewis also showed slides of the dolmen at Lanyon Quoit.—Notes on Deluge legends, tracing their distribution: N. W. **Thomas.**

Linnean Society, February 15.—Dr. A. Smith Woodward, F.R.S., vice-president, in the chair.—A lantern demonstration of the developmental changes in Zooglœa: Dr. H. C. **Bastian.** Masses of Zooglœa in their early stage were first shown, in which the constituent bacteria were plainly recognisable. The growth of the masses, their alteration in appearance and in reaction to staining fluids, together with the progressive segmentation which they undergo, were revealed by other specimens. Segmentation was shown to progress until minute spherical or ovoidal units were produced. During the first three to five days, while these changes are occurring, the masses remain colourless and the ultimate segmentation units develop into flagellate Monads, or, more rarely, into equally minute Amœbæ—myriads of one or of the other of these forms appearing (all of about the same size) where a few hours before they were absent. Later, from fifth to tenth day, the ultimate segmentation units of other masses appear as aggregates of brown fungus-germs. Often the masses as a whole become brown before segmentation has much advanced, and the different stages were shown by which the bacterial aggregates are completely converted into masses of brown fungus-germs, together with the development of hyphæ therefrom. All the stages in the complete conversion of the Zooglœa masses into Monads or Amœbæ in the one case, or into brown fungus-germs in the other, are clearly recognisable, though it is impossible to say from the appearance of the masses in their early stages which of these three interchangeable forms of life will ultimately be produced.—The structure of *Isis hippuris* (Linnæus): J. J. **Simpson.** The species in question is the only one remaining in the genus, the other eighteen formerly included having at various times been removed to other genera of Alcyonaria. It is widely distributed, being found in Iceland, the Mediterranean, Indian and Pacific Oceans, though no specimen was found in the *Challenger* collections. The investigation was conducted on a series of specimens obtained by the Indian survey ship *Investigator,* from the surf-line and from 20 fathoms in the Andaman Sea.—Note on the distribution of the genus Shortia (Torr. and Gray): B. Daydon **Jackson.** By the aid of lantern-slides, the distribution of the genus was indicated, and various species described, with their distinguishing characters shown.

Zoological Society, February 20.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—A new drawing of the skeleton of the Triassic rhynchocephalian, *Rhynchosaurus articeps*, from the Keuper Sandstone of Shropshire: Dr. A. Smith **Woodward.**—Breeding experiments with Lepidoptera: L. **Doncaster** and the Rev. G. H. **Raynor.** The species used were *Angerona prunaria* and its var. *sordiata,* and *Abraxas grossulariata* and its var. *lacticolor.* In *A. prunaria* the banding of the var. *sordiata* was dominant over its absence in the type, but the speckling characteristic of the type appeared in the heterozygote, so that the latter was both banded and speckled. The characters appeared to segregate in the typical Mendelian manner, but in several families there was an excess of *prunaria* over *sordiata.* In *A. grossulariata* the var. *lacticolor* was a Mendelian recessive, but was normally found only in the female. By pairing a heterozygous male with a *lacticolor* female, *lacticolor* males and females were obtained. *Lacticolor* male × female gave only *lacticolor*; *lacticolor* males by heterozygote females had given all males of the type, all females *lacticolor.*—Tracheophone Passeres: W. P. **Pycraft.** The author proposed to make the Tracheophone Passeres one of four great divisions of the passerine stem. The most primitive of the divisions would contain the Eurylæmidæ, Cotingidæ, and Philepitta. The second would be represented by the Tracheophonæ, the third by the Tyrannidæ and Pittidæ, and the fourth by the rest of the Passeres.—A collection of mammals made by Mr. C. H. B. Grant at Knysna, and presented to the National Museum by Mr. C. D. Rudd: O. **Thomas** and H. **Schwann.** The collection consisted of about 150 specimens, belonging to 31 species or subspecies, of which the most noticeable was Mrs. Rudd's golden mole (*Amblysomus corriae*), the description of which had already been laid before the society. A new generic name, Nototragus, was applied to the grysbok, which differed from the other

members of Raphicerus by its possession of supplementary hoofs.—Habits of the Australian lung-fish (*Ceratodus forsteri*) as observed in the society's menagerie: Prof. B. **Dean.**

Royal Meteorological Society, February 21.—Mr. Richard Bentley, president, in the chair.—Report on the phenological observations for 1905: E. **Mawley.** As affecting vegetation, the weather of the phenological year ending November, 1905, was chiefly remarkable for the dryness and mildness of the winter months, the drought and frosts in May, the long spell of hot and dry weather in July, and an exceptionally cold period in October.—Brief discussion of the general features of the pressure and wind conditions over the trades-monsoon area: W. L. **Dallas.**—The dispersal or prevention of fogs: Dr. W. B. **Newton.**

CAMBRIDGE.

Philosophical Society, January 29.—Prof. Thomson, vice-president, in the chair.—The expansion of a gas into a vacuum and the determination of the specific heat at constant pressure for gases: G. F. C. **Searle.** If gas, which is initially stored in a receiver at a high pressure, be allowed to expand into an exhausted vessel, and if the temperature of the whole mass of gas be allowed again to become uniform, without any gain or loss of heat, the final temperature (t') will differ from the initial temperature (t) unless U, the energy of a gram of gas, is independent of the volume. For a gas obeying Van der Waals's equation $(p+a/v^2)(v-b)=Rt$, it is shown that, when the volume of one gram increases from v to v', the change of temperature is given by $t-t'=a/C_v(1/v-1/v')$. Regnault's method of determining the specific heat of gases at constant pressure is shown to be an extreme case of the Thomson-Joule porous plug experiment.—The action of radium and other salts on gelatin: W. A. D. **Rudge.** The author has shown that barium salts produce the same effect upon gelatin as is the case with radium salt, and concludes from his experiments that radium has no specific action upon gelatin, any result obtained being due to the action of the barium in the radium salt upon the sulphur compounds present in the gelatin.—A novel instrument for illustrating the magnetic properties of iron: A. H. **Peake.** In this instrument a strong magnetic field is produced by sixteen bar magnets; this field, which is normally horizontal, may be slightly inclined at will by rotating a turn-table, to which the permanent magnets are attached, through a few degrees. The specimen of iron under test is very thin in proportion to its length; it is supported in a freely pivoted cradle to which a control weight and a long pointer are attached; the axis of the cradle is in the same straight line with that of the turn-table.—The susceptibility of iron in colloidal solution: E. F. **Burton** and P. **Phillips.** The paper is an account of experiments made to determine the susceptibility of a colloidal solution of iron in methyl alcohol. The susceptibility found indicates that iron in colloidal solution has much stronger magnetic properties than it would have if it existed merely as a ferric (or ferrous) salt in the solution; on the other hand, the magnetic properties are weaker than those of pure iron. The results seem to point to the conclusion that each particle in the colloidal solution consists of a core of pure iron surrounded by a layer of some compound of iron, *e.g.* the hydroxide.

MANCHESTER.

Literary and Philosophical Society, January 16.—Sir William H. Bailey, president, in the chair.—Behaviour of liquid films formed from a solution of saponin in water: H. **Stansfield.** Although saponin films have very little mobility, they are capable of becoming extremely thin. The limiting thickness of a black saponin film is comparable with that of the thinnest soap film. In the process of thinning, the saponin films exhibit a grey stage; and there are two characteristic abrupt changes in thickness, the first from the white of the first order to the grey, and the second from the grey to the black.—Battack printing in Java: J. **Allan.** The process of battacking is more akin to dyeing than to printing. The white cotton is first freed from the starchy and saline matter of the "finish" by frequent washings and exposure in the wet condition to the sun. When thoroughly dried and cut into sarong lengths it is ready to be printed. The whole fabric is immersed in a dye bath, the parts not intended to be coloured being protected by previously overlaying them with a coating of wax, placed on in such a way as to form a design. In the coarsest cloths the design is drawn in with a thick brush by the women; in those of finer quality it is stamped with a metal die by the men.—Remarks on the germinal layers of vertebrates and on the significance of germinal layers in general: J. W. **Jenkinson.**

January 30.—Mr. Francis Nicholson in the chair.—The origin of the salt in the sea: R. L. **Taylor.** The paper was a contribution to the controversy which began more than thirty years ago between Dr. Sterry Hunt and David Forbes. Hunt (whose views Mr. Taylor endorsed) contended that on the original cooling of the globe, and before the condensation of the water, the alkali metals, sodium and potassium, existed in the crust of the earth entirely as silicates, the primitive atmosphere containing the chlorine as hydrochloric acid, and also probably sulphuric acid. When the water condensed these acids dissolved in it, and the primitive ocean was thus really dilute acid. This acid, however, soon became neutralised as it vigorously attacked the silicates of which the crust of the earth was composed. The calcium and magnesium, dissolved out of the primitive rock at the same time as the alkalies, have been gradually replaced by sodium carried down as carbonate by rivers.

February 13.—Sir William H. Bailey, president, in the chair.—Report on the recent Foraminifera from the coast of the island of Delos, part iii., Lageninæ: H. **Sidebottom.** The writer directed attention to the points of difference that occur in the same species, and stated that some of the species found have not previously been reported from the Mediterranean. Drawings of the most interesting forms obtained were exhibited and described.

PARIS.

Academy of Sciences, February 26.—M. H. Poincaré in the chair.—Researches on some metals and minerals found in the excavations at Susa, in Persia: M. **Berthelot** and G. **André.** The objects examined come from the earliest Elamite period, earlier than 750 B.C., and analyses are given of articles of silver, copper, bronze, lead, and lead silicate.—The propagation of a movement round a centre in an elastic homogeneous and isotropic medium: study of the wave correlative to the variations in density: J. **Boussinesq.**—Some difficulties presented by the estimation of carbon monoxide in gaseous mixtures: Armand **Gautier** and M. **Clausmann.** Synthetical mixtures of carbon monoxide with hydrogen and air were analysed by absorption with cuprous chloride and explosion with oxygen. It was found that the absorption by cuprous chloride, even in two successive treatments, was never complete, and that measurable amounts of carbon monoxide escaped oxidation by explosion.—An important inequality in the study of quasi-waves of shock: P. **Duhem.**—The addition of hydrochloric acid to isobutylene oxide, $\underset{\quad\quad O}{(CH_3)_2.C—CH_2}$: Louis **Henry.** Isobutylene oxide reacts with concentrated hydrochloric acid, a new chlorhydrin, $(CH_3)_2.CCl.CH_2(.OH)$, being formed. The starting point for the preparation of the isobutylene oxide was the isomeric chlorhydrin, $(CH_3)_2.C(OH).CH_2Cl$, prepared from monochloracetone by Grignard's reaction. The physical and chemical properties of these closely related isomers are compared.—M. Heim was elected a correspondant for the section of mineralogy in the place of M. de Richthofen.—The perpetual secretary announced the death of M. A. F. A. Bienaymé, correspondant for the section of geography and navigation.—Observations of the Brooks comet (1906*a*) made with the large equatorial of the University of Bordeaux: E. **Esclangon.**—The indeterminateness of a function of a variable in the neighbourhood of a transcendental singularity: Pierre **Boutroux.**—Fourier's series: Léopold **Fejér.**—The integrals of a differential equation in the neighbourhood of a di-critical point: H. **Dulac.**—The application of the analysis of Dirichlet to quadratic forms with coefficients: P. **Fatou.**—The theory of spectra: Ivar **Fredholm.**—The vibrations of an elastic body the surface

of which is at rest: A. **Korn.**—A particular case of the problem of n-bodies: Thadée **Banachiewitz.**—The exact significance of Carnot's principle: Louis **Fredey.**—Lævorotatory lactic acid: E. **Jungfleisch** and M. **Godchot.** l-Lactic acid is much more easily transformable than the d-acid into the $(d+l)$ acid, and increased care in working is in consequence necessary. The crystallised lævo-acid melts at 27° C., at approximately the same temperature as the dextro-acid.—The cysts of Glœosporium and their *rôle* in the origin of yeasts: P. **Viala** and P. **Pacottet.**—*Stellosphaera mirabilis,* a new larva probably belonging to an abyssal form: R. **Kœhler** and C. **Vaney.**—The recuperative effects of raw meat after fasting: Charles **Richet.** Experiments on dogs comparing the recuperative effect after fasting of cooked meat, broth, and raw meat showed that the latter food is the most efficacious.—Study of the variations in the toxicity of the contents of the small intestine: modifications of the blood: MM. **Charrin** and **Le Play.**—The tectonic of the massif of the Dent Blanche: Emile **Argand.**—The geology of Iférouane: R. **Chudeau.**

New South Wales.

Royal Society, December 6, 1905.—Mr. H. A. Lenehan, president, in the chair.—A method of separating the clay and sand in clay soils and those rich in organic matter: L. **Cohen.**—Latitude of the Sydney Observatory; appendix to a paper on the provisional determination of astronomical refraction, from observations made with the meridian circle instrument of the Sydney Observatory: C. J. **Merfield.** An alteration in the accepted value ($\phi_0 = -33° \ 51' \ 41''\cdot55$) is regarded as unwise until the question is more completely discussed.—Sociology of some Australian tribes: R. H. **Mathews.** The author stated his opinion that among the social institutions of a primitive people there is none of greater interest and value to the anthropologist than the study of these social systems. He also expressed his conviction that neither "sexual promiscuity" nor "group marriage" has ever existed among the Australian aborigines.—An undescribed species of Leptospermum and its essential oil: R. T. **Baker** and H. G. **Smith.** "The lemon-scented Leptospermum," the species described in this paper, occurs in the north coast district of New South Wales and the southern coast district of Queensland. It is a shrub attaining a height from 6 feet to 12 feet, with erect branches and small, lanceolate, ovate leaves, the flowers occurring in the axils of the leaves on the upper branchlets. The fruits measure about two to three lines in diameter. Its differentiation from described species is based on both morphological and chemical characters, although the former are alone sufficiently marked to warrant its specific rank.

DIARY OF SOCIETIES.

THURSDAY, March 8.

Royal Society, at 4.30.—The Microscopic Changes in the Nervous System in a Case of Chronic Dourine or "Mal de Coït," and Comparison of the Same with Those found in Sleeping Sickness: Dr. F. W. Mott, F.R.S.—On the Relationship between Hæmolysis and Phagocytosis of Red Blood Cells: Dr. R. D. Keith.—Upon the Properties of an Antityphoid Serum obtained from the Goat: Dr. A. Macfadyen.

Royal Institution, at 5.—The Physiology of Plants: F. Darwin, For. Sec. R.S.

Institution of Electrical Engineers, at 8.—A New Single-Phase Commutator Motor: V. A. Fynn.

Mathematical Society, at 5.30.—On Function Sum Theorems connected with the Series $\sum_1^\infty x^n/n^2$: Prof. L. J. Rogers.—On Sommerfeld's Diffraction Problem and on Reflection by a Parabolic Mirror: Prof. H. Lamb.—On Series of Zonal Harmonics: Prof. T. J. I'A. Bromwich.

FRIDAY, March 9.

Royal Institution, at 9.—Some Dietetic Problems: Dr. R. Hutchison.

Physical Society, at 8.—The Velocities of the Ions of Alkali Salt Vapours at High Temperatures: Prof. H. A. Wilson.—Some Experiments on Earth Currents at Kew Observatory: Dr. Harker.

Royal Astronomical Society, at 5.—Preliminary Account of Flash Spectra taken August 30, 1905: Dr. S. A. Mitchell.—Note on Certain Anomalies observed in Radial Velocity Curves: Dr. Alex. W. THURSDAY, MARCH 15, 1906.

TEXT-BOOKS ON PLAIN AND REINFORCED CONCRETE WORK.

(1) *Cements, Limes, and Plasters: their Materials, Manufacture, and Properties.* By E. C. Eckel. Pp. xxxiv+712. (New York: J. Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 25s. 6d. net.

(2) *Cement and Concrete.* By L. C. Sabin. Pp. x+507. (London: Archibald Constable and Co., Ltd., 1905.) Price 21s. net.

(3) *A Treatise on Concrete, Plain and Reinforced.* By F. W. Taylor and S. E. Thompson. Pp. xviii+585. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 21s. net.

(4) *Reinforced Concrete Construction.* By A. W. Buel and C. S. Hill. Pp. x+434. (London: Archibald Constable and Co., Ltd., 1905.) Price 21s. net.

(5) *Concrete Steel: a Treatise on the Theory and Practice of Reinforced Concrete Construction.* By W. Noble Twelvetrees, M.I.M.E., &c. Pp. xii+218; illustrated. (London: Whittaker and Co., 1905.) Price 6s. net.

(1) THIS book gives an exhaustive account of the various processes involved in the preparation of plasters, limes, and cements, and of the examination of these materials both by chemical and by physical tests. It is probably one of the most complete treatises which has been published up to the present day on this subject, and the author justifies the thoroughness of the treatment by statistics in regard to the monetary value of the cementing material annually produced in Europe and America; in the United States the monetary value of cementing materials increased from 21,773,246 dollars in 1900 to 45,607,436 dollars in 1903.

The author classifies cementing materials under two heads, viz. simple cementing materials, which include all those produced by the expulsion of a liquid or gas through the action of heat from a natural raw material, and the setting properties of which are due to the simple re-absorption of the same liquid or gas, and complex cementing materials, which include those cements the setting properties of which are due to the formation of entirely new chemical compounds during manufacture or use. Plasters are first dealt with in group i.; the process of manufacture is explained, statistics are given as to the total production of gypsum, and details of the chemical and other properties of plasters used in building work; one chapter in this section is devoted to the manufacture and properties of lime-sand bricks, which are made by mixing sand, or gravel, with a relatively small percentage of slaked lime.

As the value of Portland cement annually manufactured in the United States is three-fifths of the total value of the output of cementing materials, it is only natural that a very large portion of the book should be devoted to the questions of the manufacture and testing of Portland cement. The quarrying and other preliminary work necessary in order to obtain the raw materials from which Portland cement is made are dealt with in a series of well written and well illustrated chapters. Then follow details of the preparation of the material for the kilns, and of the best methods to employ in burning the cement and in working the kilns; this is the first text-book on this subject in which we have found a complete and detailed account of the construction and working of the modern rotary kiln. The cementing value of Portland cement depends so largely upon the fineness and character of the grinding that the author rightly devotes much attention to a description of the various grinding machines which have been devised for this work. The last portion of the book is devoted to an account of the physical and chemical tests usually employed in testing Portland cement, and the rules drawn up in 1904 by the American society for testing materials are given in full.

(2) The original investigations which form the basis of this book were made by the author in connection with the construction of the Poe Lock at St. Mary's Falls Canal, Michigan, under the direction of the Corps of Engineers, United States Army. The book is divided into four parts; in the first section a brief account is given of the different cements and limes in ordinary use, and the processes employed in their manufacture; there is a good description of the rotary kilns now often used in making Portland cement.

In part ii. the author deals with the various physical tests usually enforced in examining Portland cement in order to ascertain its quality and its suitability for various purposes, and a series of tables is given of the results of tests made by the author in connection with the works at St. Mary's Falls Canal. In the last chapter of this section the author explains carefully the method adopted at these works for recording the receipt of Portland cement from the manufacturers, the methods adopted for storing it, and for keeping the records of the various tests made from sample barrels selected from each delivery; this chapter will be found very useful as a guidance by any engineer who may have to undertake similar work.

The question of the correct proportion of the various ingredients in concrete, and the methods employed in mixing them, are dealt with in part iii., and a number of tables is given for enabling in any case a determination to be made of the percentage of voids present in broken stone of various classes when broken to varying degrees of fineness; this portion of the book is of an extremely practical nature, and contains a great deal of useful information. The last portion of this section is devoted to the testing of concrete, and the results of a carefully arranged series of tests carried out by the author are given in tabular form. This portion of the book also deals with the question of the determination of the modulus of elasticity of concrete, and with such important points as the

change in volume during the process of setting, resistance to fire, and other matters of a similar nature.

The last section of the book, part iv., is devoted to a description of the various classes of work for which cement concrete is most useful, and the question of reinforced concrete, or concrete-steel, as the author prefers to call it, is taken up. In the last few chapters the methods of applying concrete—both plain and reinforced—in large structures such as subways, arches, reservoirs, retaining walls, dams, &c., are fully explained. The book has a good index.

(3) The whole question of concrete work, both when used by itself and when employed in combination with steel, or reinforced concrete, as it is technically known, is fully dealt with in this elaborate treatise. The first portion of the book is devoted to the properties of Portland and other cements, and includes an interesting chapter which deals with the chemistry of hydraulic cements, and which has been specially written for the book by a chemist, Mr. S. B. Newberry. The authors then deal with the question of the ordinary standard tests of Portland cement, and quote the recommendations of the French Commission of 1893, and of the special committee of the American Society of Civil Engineers, appointed in 1904. There are a number of first-rate illustrations of the various appliances which are needed, and full explanations are given as to the best way of carrying out these standard tests. In addition to the standard tests, special tests, such as those on compression, adhesion, &c., are also discussed. This portion of the book will be found extremely useful for reference purposes.

Two chapters deal with the questions of the method of determining the laws of volumes and voids in concrete work, and the right methods of proportioning the ingredients used in making are explained in detail. The methods described may seem almost too elaborate, but there is no doubt that it pays well when concrete is to be used on a large scale to spend a considerable amount of time and trouble beforehand in determining exactly the best possible mixtures of cement, sand, and broken stone in order to produce the most economical as well as the strongest concrete suitable for the work which has to be carried out.

The authors then begin the subject of reinforced concrete, and, after discussing the values which should be used for the moduli of elasticity of concrete, both in tension and compression, go on to deal with the problem of the moment of resistance of a reinforced beam. The formulæ obtained are fairly simple, and may be said to be approximately correct, since the neglect of the tensile stress taken up by the concrete is perfectly reasonable in designing such beams. It appears to us very inadvisable in our present state of knowledge to attempt to use extremely elaborate formulæ in calculating the strength of reinforced beams, since the values obtained by different experimenters, and even by the same experimenter, for the moduli of elasticity of concrete differ by such large amounts, and the assumption that the stress-strain diagram is a parabolic curve seems to us quite unwarranted by the experimental data available up to the present time.

The authors then give some convenient tables for use in the calculation of the strength of beams and slabs which are continuous over supports, and work out a number of examples to illustrate the use of these tables. In dealing with the mixing of concrete, a number of illustrations is given of the various types of mechanical mixers now used when concrete has to be made on a large scale, including mixers fitted with automatic measuring plants in order to keep the proportions of the various materials absolutely uniform. A special chapter in this section has been written for the book by Mr. R. Feret upon the effect of sea-water upon concrete.

A few chapters then follow on the question of the effect of frost upon concrete, both during the time of depositing the concrete and after the concrete has been deposited, upon the necessary proportions of the various ingredients in order to secure absolute water-tightness in any given mass of concrete, and upon the protection afforded to iron and steel when used in reinforced concrete against fire and rust. The remaining chapters of the book are devoted to details of concrete work in various situations, such as sidewalks of streets, floors and walls of buildings, foundations and piers for bridges, retaining walls, sewers, subways, arches, reservoirs, and tanks, and the most economical method of strengthening such concrete by steel reinforcements. A very good bibliography of the subject, and some appendices dealing with the formulæ for the strength of beams, conclude a very valuable book.

(4) This is a treatise for engineers engaged in the design and construction of works in reinforced concrete, and is based mainly on American practice. The book is divided into three parts; in part i., for which Mr. Buel is responsible, after a brief explanation of the properties of cement concrete and steel, the methods of calculation are dealt with; simple formulæ are deduced for the strength of beams, both for the case when the tensile strength of the concrete is taken into account, and when it is neglected; the more important of the empirical formulæ, such as those due to Thacher, Christophe, and Hatt, are then explained, and two very complete tables are given for the safe loads in reinforced slabs of various spans, based on Thacher's formula.

The design of reinforced columns is then discussed, and the author by a series of tables shows how closely the strengths of such columns, deduced from the formulæ he gives, agree with the actual crushing strengths obtained in a series of tests at the Massachusetts Institute of Technology. The application of this system of construction to retaining walls, dams, sewers, &c., is very fully explained, several neat graphical constructions being given; and in this chapter the author deals with the very important problem of the use of steel reinforcement to prevent the cracks liable to occur in large concrete structures, such as dams and retaining walls, due both to shrinkage in setting and to thermal stresses, and he is of opinion that high carbon steel is more economical for this purpose.

In the last chapter of this section the testing and

design of reinforced concrete arches are taken up; after a brief explanation of the elastic theory and its application to the determination of the stresses in any arch, Thacher's formulæ for reinforced concrete arches are given, and their use in practice explained by the help of three typical examples of such arches, a highway bridge of two spans, each of $42\frac{1}{2}$ feet, a single-line railway bridge of 72-feet span, and, lastly, a small semicircular arch culvert of 15 feet span. These three examples are completely worked out, the necessary graphical constructions being shown in full in three plates; this chapter will undoubtedly be found very useful to any engineer who is engaged in the design of such arches.

Parts ii. and iii. are the work of Mr. Hill, and deal respectively with representative structures and methods of construction; the following branches of work are dealt with:—foundations of various types, including reinforced concrete piles, floors, walls and arches in buildings, and columns. The illustrations selected, though largely American, include also a number of cases of work carried out in Europe on the Hennebique system. The application of reinforced concrete to large bridges and culverts is illustrated by a number of structures which have recently been put up in France on the Monier system, and it may be pointed out that some hundreds of bridges of this type have now been erected, principally in Germany and Austria.

The last section of the book, on methods of construction, is naturally largely taken up with the description of the various forms necessary in elaborate reinforced concrete work. The future security of the work depends entirely upon the care with which the forms are designed and erected, and the economy of the work is largely dependent upon forms so designed that they can be rapidly put into position, readily taken down, and readily re-erected on a fresh section of the work. Many valuable hints and labour-saving suggestions will be found in this portion of the book. The author has evidently based this section upon experience of a very varied character in the erection of reinforced concrete structures.

(5) This is another of the somewhat numerous text-books which have appeared within the last few months dealing with the important subject of reinforced concrete. The author points out that the use of steel merely embedded in stone or concrete, as in the well known skeleton system of construction, does not develop the best properties of each of these materials—reinforced concrete alone enables full advantage to be taken of the special qualities of both the steel and the concrete.

The first portion of the book deals with the physical properties of the two materials, concrete and steel, and a number of carefully selected tables is given of tests of these materials. The general theory of concrete-steel beams is then considered, and special emphasis is laid upon the necessity of an accurate knowledge of the moduli of elasticity.

We are afraid, however, that the author has fallen into confusion of thought in discussing the question of the position of the neutral axis; on p. 43 he refers to an imaginary beam of concrete and steel, and appears to consider that each square inch of the concrete will carry the same total stress, ignoring altogether the variation in intensity of stress with distance from the neutral axis; and again, in chapter iv., when discussing the position of the neutral axis, he states that the position of this is affected by the fact that the compressive strength of the material (concrete) is greater than its tensile strength. Surely there is confusion here between strength and modulus of elasticity, and this confusion seems to run through all the rules and calculations for the position of the neutral axis. This portion of the book certainly requires to be carefully revised if it is to become a trustworthy text-book on the subject.

The subject of floor design in concrete and steel is taken up, several large floors constructed on the Hennebique system are fully described, and tables are given of working stresses which can be allowed, and the building rules which have been laid down by various authorities in connection with the design of such floors. The application of reinforced concrete to foundation work in bad soils is discussed, and the author shows that by the use of this type of construction the depth to which the foundation must be taken can be very considerably reduced. The last chapter discusses the construction of reinforced concrete columns, special attention being given to Considère's hooping method.

CHEMISTRY FOR SCHOOLS.

Notes on Volumetric Analysis. By J. B. Russell and A. H. Bell. Pp. viii+94. (London: John Murray.) Price 2*s.*

Introduction to Chemical Analysis. By Hugh C. H. Candy. Pp. xii+114. (London: J. and A. Churchill, 1905.) Price 3*s.* 6*d.* net.

An Elementary Text-book of Inorganic Chemistry. By R. L. Whiteley. Pp. viii+245. (London: Methuen and Co.) Price 2*s.* 6*d.*

Elementary Chemistry, Progressive Lessons in. By F. R. L. Wilson and G. W. Hedley. Pp. xii+168. (Oxford: The Clarendon Press, 1905.) Price 3*s.*

A Three Years' Course of Practical Chemistry. By George H. Martin and Ellis Jones. Pp. viii+112. (London: Rivingtons, 1906.) Price 2*s.*

IT seems to have become a recognised practice for schools and colleges to produce their own small text-books or notes on some portion of the science curriculum, first for internal use, and then for the benefit of outsiders. Whether this multiplication of little books is desirable is somewhat questionable. Without going so far as to say that these small books conduce to cramming or getting through examinations, there is always a slight lurking suspicion about this point. Our various "examination" boards are perhaps answerable for the small book production.

Mr. Russell's book is intended, no doubt, for use on the working bench. The directions for working are short, mainly to the point and in logical order, but surely they are too frequently repeated.

After about twelve pages of instructions and examples on the use of permanganate, the student is still told to weigh out so much ferrous salt, make up to so much, &c.; little room is left for the student to think and find out for himself.

After the idea of "normal solution" has been once grasped, many of the directions might be left out. One somewhat objectionable point noted is the direction to weigh out a certain definite quantity of a substance, say 5.3 grams. This is not an easy matter for beginners. It is better to take a weighed quantity and make up solution to the desired strength by addition of the calculated proportion of water.

The ground covered ranges from acid and alkali through permanganate to silver and thiosulphate, preceded by a good description of the use of the burette, &c. The book will no doubt be useful, especially with large classes where the instructor is not able to get rapidly around to the students.

The preface of Mr. Candy's book informs us that the methods and processes of analysis and synthesis have been chosen to meet the requirements of students preparing for parts i. and ii. of the preliminary scientific examination in the University of London and the first examination of the joint board. After a sensible introduction, chapters follow on the identification of bases and acids, methods of separation and tests of purity, and a very useful chapter on preparations. In the latter section are included examples of preparations of mineral salts, acids, esters, alcohol derivatives, &c. The processes of taking a melting point and a boiling point might have been illustrated by a sketch. The preparation method for aldehyde is somewhat dangerous in inexperienced hands. It is safer to drop alcohol, very slowly, into the warm bichromate mixture and distil off the aldehyde as fast as formed. Some short chapters on equivalent and volumetric operations complete the book. The matter is clearly expressed, and the book will be useful for the class of students for whom it is intended.

The first forty-two pages of Mr. Whiteley's book deal with physical changes and physical properties. The book is rather freely illustrated by diagrams of apparatus, and the descriptions and explanations are generally quite clear, full, and understandable. It is designed for the use of those studying elementary chemistry on the lines of the Board of Education syllabus. The purely chemical sections include air, water, common salt, chemical theories, compounds of nitrogen, carbon and sulphur. There are appendices on solubilities of salts, questions and answers to calculations. The book should be very useful, especially to students unable to attend courses of experimental teaching or lectures.

The volume by Messrs. Wilson and Hedley is intended as a school course for beginners. It is entitled "Elementary Chemistry," but a large part of the book is concerned with necessary matters of elementary physics, such as measuring, length, areas, volume, the thermometer, density, solution, evaporation and boiling, Boyle's law, &c. The book is simply and clearly written, and illustrated by useful diagrams. Strictly speaking, there is no chemistry in the book, but we think all boys intending to commence that subject would benefit exceedingly by working through the excellent course here given.

The plan of instruction set forth by Messrs. Martin and Jones is to perform some experiments on a given substance such as mixing "salammoniac with quicklime and heating in a test tube." The inquiring student is then required to write out an account of what he notices, and to compare the results with those obtained when one of the substances is heated alone. Commenced with moderately young students who have not the bogey of an examination paper, or a particular syllabus, throwing a baleful shadow over them, this plan should produce excellent results. The book could scarcely be used to full advantage by students working alone, but with a sympathetic teacher at hand to fill in necessary explanations we think the volume a valuable addition to the host of books already available.

W. R. H.

CERTAIN MODERN VIEWS ON PATHOLOGY

Introduction à la Pathologie générale. By M. Félix le Dantec. Pp. x+504. (Paris: Félix Alcan, 1906.) Price 15 francs.

IN this work the author has grouped together a large and heterogeneous mass of information and speculation, always interesting and always fascinating. The first line of his introductory remarks leads us from the tubercle bacillus to the Milky Way, from the infinitely small to the immeasurably large, and we are soon assured that everything that exists in this formidable interval of space can be subject to investigation, provided it, in any way, can influence us. This promise holds good for everything, from an earthquake on the satellite of Sirius to an analogous occurrence in the interior of an electron; and so on, until after forty pages of pleasant reading we learn that the object of the book is principally to support the views of M. Bordet "and some others" as to the question of immunity. The theories of Ehrlich and his followers give a purely chemical interpretation of the facts of immunity, and are unsatisfactory inasmuch as they confound colloidal changes with chemical changes, properly so called. Ehrlich's views, he says, threaten to become to general pathology what Weismann's have been to biology.

> "It is always dangerous to give names to things which do not exist—this is to create entities, of which it will afterwards be found extremely difficult to disembarrass oneself."

The author divides his book into two great sections. In the first he desires to advance slowly, to return frequently to the same subjects, so as not to come into too violent collision with the habit of thought of those who have for a long time been familiarised with the language of chemistry; also to give a short account of such of the properties of colloids as may be of interest to the biologist, and to sketch the main lines of the physical theory of serotherapy. Thus he leads the reader to the "notion" of the three heredities, chemical, physical, and symbiotic heredity. The

first part concludes with certain considerations as to the influence of radiations on the equilibrium of living substances.

In the second division of the work the author proceeds to render more precise the language prepared in the first part of his study. He reviews the more important types of infection, and particularly considers intracellular parasitism and symbiosis; then he passes on to the phagocytic studies of M. Metchnikoff, and uses a language different from the vitalistic expressions of the great Russian *savant*. Next comes the considerations of the comportment of the living organism towards injections of dead colloids, thus leading up to the study of infection proper, *i.e.* disease due to living micro-organisms. The above abstracts will suffice to show the aim of the author's book, and chiefly he desires to use "*the language of equilibrium*," language borrowed from physical chemistry. He holds the law of Le Châtelier valid for the modification which an organism undergoes when it triumphs over infection. "The modification produced in a system of bodies in a state of equilibrium by a variation of one of the factors in the equilibrium is of such a nature that it tends to oppose itself to the variation that determines it." His position is even more clearly defined on p. 184, where he says that he wishes to show that if the immunities that result from the resistance of organisms to infection resemble the phenomena of physical chemistry, the resemblance is exclusively on the physical side. He finds that questions on immunity and serotherapy are discussed in the language of chemistry, even by those investigators who do not accept the theories of Ehrlich—therefore the very words used are filled with unjustifiable hypotheses, and give an inflexible interpretation to phenomena. For example, the partisans of the chemical theory of serums admit the existence of two definite and complementary substances, "cytase" and "fixative," the former thermolabile, the latter thermostable, and these thermic relations, according to M. le Dantec, suggest that these substances—even if chemically definite bodies—act in virtue of their *physical* character rather than in accordance with their *chemical* structure.

The phenomena of bacteriolysis receive at the hands of Ehrlich a purely chemical interpretation; M. le Dantec deliberately states that the chief fault in Ehrlich's theory is that the serum-producing animal must have an immediate and profound knowledge of chemistry. This can scarcely be seriously meant.

Nowhere does he give a complete account of the views on immunity and toxins held by Ehrlich, nor is this to be looked upon as a fault, inasmuch as those of Ehrlich's opinions that he does consider he regards as entirely untenable. Still, this omission (if such it be) shows that the book will be of little use to a student really needing an introduction to general pathology, however interesting and instructive the work may be to the thoroughly equipped investigator; and to the latter the learned author doubtless addresses himself. First and foremost he is a biologist, and, moreover, is imbued with the belief that pathology is capable of throwing a flood of light on biological questions.

Many pages of the work remind us of the author's well known papers in the Annals of the Pasteur Institute, and these pages will be read by many with reminiscent pleasure.

Nowhere is the author more interesting and lucid than in his discussion of Mendelian or discontinuous heredity; his quotations are apt and instructive; his own remarks carry with them the imprint of careful study and original thought. In this connection he replaces the "*representative particles*" of Darwin and Weismann by the Pasteurian word "*microbe*" meaning thereby *particles productive of diatheses*—and claims that by so doing he loses nothing in the narration of the facts, while gaining the advantage of placing the diatheses (characters of Mendelian heredity) apart from the characters of heredity properly so-called.

The book is well worth careful reading, and the author is to be congratulated on a work which will challenge the attention of the more advanced students of pathology. WM. ST. C. SYMMERS.

OUR BOOK SHELF.

Die optischen Instrumente. By Dr. Moritz von Rohr. Pp. v+130. (Leipzig: B. G. Teubner, 1906.)

THE aim of this little book, one of a series dealing popularly with various subjects of scientific or general interest, is to give a simple account of the development and modern theory of optical instruments, and to make clear to readers possessing no special technical knowledge the main features of their optical construction. The treatment is largely based on the work of Abbe; and in the introductory chapters, which deal with the general principles governing the formation of optical images and the consequences dependent on the characteristics of the eye, special attention is given to the question of aperture and the limits of the image-forming pencils, and to the manner in which the perspective of a picture may be modified in the image. In the application of these considerations to the photographic lens, the microscope, and the telescope, there is some novelty and interest. In other respects a clear and concise account is given of the main properties and aberrations of the different instruments, whether for objective or subjective use, with some brief historical notes. The section on the photographic lens is followed by useful particulars as to enlarging and projection apparatus; the description of the microscope includes a short explanation of Abbe's theory of microscopic vision, of the relation of "numerical aperture" to resolving power, and of the sine law, and even admits of reference to the possibilities of photomicrography with ultra-violet light. To the description of the ordinary forms of telescope are added some notes on the prism binocular as constructed by the Zeiss firm. The diagrams and illustrations are noticeably well drawn and clearly printed.

Second Year Chemistry, a Handbook for Laboratory and Class Work. By Prof. Edward Hart. Pp. vi+165. (Easton, Pa.: The Chemical Publishing Co., 1905.) Price 1.25 dollars.

THE plan of this book is to begin, after a few theoretical generalities, with some careful quantitative determinations. Thereupon follow qualitative analysis, chemical arithmetic, and, finally, more quanti-

itative analysis. The treatment is marked throughout by a considerable degree of originality, and the book appears agreeably free from the domination of an examination syllabus or of the authority of any particular school. It is unusual to find the determination of silicon in pig-iron or steel in an elementary book, and so also the use of a Hempel gas apparatus; but there is, after all, no good reason why the practical work of elementary students should not be interspersed with exercises of this more technical kind. It is astonishing what sanctity is still attached to the established order of practical chemistry, and it is not the least interesting feature of this book that it is markedly unorthodox. Most teachers will admit that they may profit by carefully inspecting the plans of instruction adopted by their well accredited colleagues, and such a remark may certainly be made of Prof. Hart's little book. A. S.

La Nature et la Vie. By Henry de Varigny. Pp. ii+356. (Paris: Armand Colin, 1905.) Price 3.50 francs.

In a pleasant and easy fashion the writer of this book carries the reader from the beginnings of life to its termination by death. The origin of life on this planet, the vital phenomena of the lower and higher forms of vegetable and animal life, the part played by bacteria in the fertilisation of the soil, the evolution of living forms, parasitism, the multiplication of animals and plants, the beginning of the end, the problem of death, and the immortality of the protozoa are a few of the subjects dealt with. The book may be recommended as a good popular introduction for the educated but non-scientific reader to general biological problems.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

A Plea for Absolute Motion.

NEWTON believed in the possibility of absolute motion (*i.e.* motion in space not necessarily relative to other material bodies), founding his argument on the fact that the rotation of a planet might be detected by experiment on the planet itself without reference to outside bodies. Newton's reasoning is unanswerable, but it only takes us part of the way. Though it proves that using the principle of gyrostatic action we can determine direction in space absolutely, it fails to distinguish one parallel line from another. We can only observe relative motion. This statement, which no one doubts, is generally taken to be synonymous with the assertion that nothing but relative motion will ever be known. So firmly is this generalisation rooted in the present generation of philosophers that I am afraid the expression of a contrary opinion will only result in placing its author on the "Index" of De Morgan's Budget of Paradoxes.

It is therefore with considerable hesitation that I venture to raise the question whether we are not most of us in our innermost hearts believers in absolute motion, and whether a good deal of the persistence with which we try in our lectures to prove that no meaning can be assigned to absolute motion does not arise out of the desire to repress our own rebellious doubts. As regards the direct evidence of observation we are all agreed, but if from the outset we limit the results of reasoning to that which may directly be controlled by experiment, we must throw overboard a good many theories which are firmly believed in by men of science. I will try to show that it is almost impossible to exclude the idea of absolute motion from our discussions, and that some of our scientific definitions tacitly admit it.

The observed motion of the solar system through the stellar universe has frequently been introduced into the discussion of relative motion, but I do not think that its full importance has been recognised. The thesis I wish to maintain is that the question whether our solar system possesses velocity not only relatively to the stellar universe, but absolutely in space, constitutes a definite problem to which a scientific meaning can be attached. It is immaterial to my purpose whether our present observations are sufficient to allow us to draw any definite conclusions. If the validity of the question itself is admitted, my point is gained.

In order to free the main issue from the uncertainties arising out of the imperfections of our observations, I will base my argument on an ideal condition of the universe which resembles the real universe sufficiently to be admitted as a possibility. The displacement of a star relative to the solar system may be determined in two ways. While telescopic observations give us the angular motion in a plane at right angles to the line of sight, spectroscopic observations allow us to determine radial velocities. To determine velocities by means of the telescope we require to know the distance of the stars, but the determination of parallax is a question of instrumental perfection and of long-continued observation. We commit, therefore, no error in principle if we imagine the parallaxes of the stars in our ideal universe to be known, so that the combination of telescopic and spectroscopic observations can determine the relative velocity in magnitude and direction.

It is a matter of history that telescopic observations alone have led to the conclusion that the solar system moves relatively to the stellar system towards a point which, as fixed by Prof. Newcomb's discussion, has a right ascension of 277°·5 and a declination of 35°. Taking this point as apex, Prof. Campbell divided the heavens into eighteen zones, obtained by drawing circles of latitude at a distance of 10° with the apex as pole. In every one of the zones which had a smaller apical distance than 90°, the average motion was one of approach to the sun, and in every one of the zones having an apical distance greater than 90° the motion was one of recession from the sun. A complete discussion gave for the line of direction, as obtained by the spectroscopic method, R.A. 277°·5, dec. 20°, the right ascension agreeing exactly with the value deduced by Newcomb, though the declination differs materially. The relative velocity found was about 20 kilometres per second.

We may now idealise this observed universe so as to simplify the argument, and bring out its essential points. Divide the heavens into a number of compartments. Let in each compartment the relative velocities be measured for a large number of stars combining the spectroscopic and telescopic method. Let u be the average velocity of each group relatively to the solar system, so that the velocity of each star in the group can be represented by $u+v$, both quantities being vectors. For the sake of argument, assume that u is the same for all groups, and that v within each group is distributed according to the law of errors. As regards v, there is no predominance of any direction (otherwise u would be affected), and its magnitude will be distributed about its mean value in a manner which we will take to be the same for all groups. The question arises: How should we interpret such observations if the facts were as stated?

It is not sufficient to say that the observations would prove a relative motion $-u$ of the sun with respect to the stellar system, for this would only represent a small part of the facts. The important point brought out by the observations is that the relative motion is observed to be the same for the mean point in each one of a great number of groups of stars. The fact that within each group the distribution follows the law of errors leads to the conclusion that the groups are independent systems, and I put the question thus: Does it require an explanation why all these independent systems should have the same vector u imposed upon them? If you admit the validity of this question, if you begin even to discuss the alternative explanation that the vector u reversed really belongs to the solar system, and indicates its velocity, you have practically surrendered to absolute motion. If there were only one star in existence showing relative motion towards the

solar system, and someone were to begin to ask: Is it the star that moves or ourselves? we should at once reject the question as absurd, and say that the two alternatives mean the same thing. But I doubt whether there will be many who would be satisfied to contemplate a stellar universe, each member of which has the same relative velocity with respect to the sun, without feeling that here is a problem which requires investigation.

The ideal case considered might be realised if we could imagine observations to be taken from a molecule in a mass of gas enclosed in a box, the observations being taken in the interval between two collisions. If other molecules could be brought within the range of observation, we should, indeed, find that for the mean point in each group containing a large number of molecules the observed relative motion has the same value, that value being the reversed velocity of the molecule itself. If there were any ordinary common-sense philosopher placed on the molecule, he would argue that his observations have really determined the absolute velocity of his place of abode in space, but his wiser colleagues will tell him that he is wrong, and that he has only determined his velocity relative to the rest of the system. The common-sense philosopher would then justly claim that he has done more than that, and point out that the whole system of molecules can be divided into a great many groups, and that the relative velocity in all the groups is identical in magnitude and direction. With our greater knowledge from outside, we know that the velocity which has been determined really belongs to the molecule, and we should probably add (though this is not a matter which the supposed observations could have proved) that it is the velocity relative to the vessel which contains the gas. But even then not all the facts which the observer on the molecule has discovered are accounted for. If the gas could be set into violent motion, without altering the velocity of the particular molecule from which the observations are made, the observer would still obtain the same value for his relative motion, but the different groups into which he has divided his space would no longer give identical values. The complete conclusion to be drawn from the original observations is, that a velocity has been determined relative to an outside body which is mechanically connected with the system, and that each group of molecules is separately at rest relatively to this outside body.

Consider now the application of this example to our problem. If we could argue by analogy we should conclude that the observed velocity of the solar system really belongs to it, and not to the stars, but that it must be taken as relative to something which is outside the stellar universe, though connected with it. If that something is material, we should be forced to the conclusion that we have determined a velocity relative to a material body which has not come into our range of observations at all. The conclusion seems too absurd to be entertained. The only alternative is to replace what in the case of the gas was the containing vessel by something immaterial, which therefore we cannot imagine to be in motion. Not being capable of motion it must be at absolute rest, and we may identify it with that abstraction to which we give the name of space. All motion relative to space is absolute motion.

It may be said that if this argument is to be applied to the actual universe, I have left out of account a large number of bodies of which we have no cognisance because they are not luminous. It is possible that these obscure bodies would, if we could observe them, show a systematic motion which would quite upset the previous conclusions. To this I reply that I have treated an ideal case which may or may not coincide with the actual one. I have expressed no opinion as to whether, on the strength of present observations, we are justified in assigning absolute velocity to the solar system; but it may be pointed out that almost every theory which we now believe to be true may some day be upset by facts at present undiscovered, which cannot be reconciled with it. Should we come to the conclusion that our solar system is in motion we may have to modify that belief in the future, but this possibility does not prevent our being justified in adopting views which are in accordance with the facts at present known.

There is an easy way out of the difficulty. When we are driven to our wits' end we have recourse to the æther. Why, then, assume absolute motion when it is so simple to say that you have determined the motion relative to the æther? We should by this device be able to calm our consciences as regards relative motion, no doubt, but at the expense of logical consistency. A moment's reflection will show that the æther has nothing to do with the question. If the æther were non-existent and the corpuscular theory of light were true, the displacement at right angles to the line of sight would still be observed, and as regards the radial velocities the contemplation of the corresponding acoustical problem is decisive. The note of the whistle of an approaching engine is quite independent of the direction of the wind. Similarly, the observed Doppler effect when the spectra of stars are examined is independent of any uniform drift there might be in the æther. No doubt we may, and probably must, consider the æther as immovable in space, and in that case absolute motion in space becomes identical with motion relative to the æther; but the direct conclusion derived from the observation of stars applies to space, and not to the æther.

All our observations of position can only be relative to some standard point. Motion involves change of position, hence motion can be relative only. This is the main argument on which the impossibility of absolute motion is founded. But it proves only that *observed* velocity must be relative, and not that there is nothing real corresponding to absolute velocity. The argument also assumes the very doubtful proposition that velocity must be derived from change of position. It may be the other way round, velocity may be the more fundamental thing, and change of position may have to be derived from it. It seems to be equally logical to take $s=\int vdt$ or $v=ds/dt$ as the equation representing the relationship between the position and velocity. Indeed, if we read Poincaré's description of how we form our ideas of space, we must be struck by the importance attached to the muscular sensation which accompanies a change of position of our bodies. To quote only one of his sentences:—"None of our sensations could have led us by themselves to the conception of space. We are led to this conception only by studying the laws according to which our sensations succeed each other." Bearing this in mind, it seems rational to start from the idea of velocity as rate of change of position, and deduce the idea of position from it. Rest would become an abstraction, and would have to be defined as an infinitely small motion.

There is, however, another way of looking at it. It is known that it is much more difficult to convince ourselves of the objective nature of time than of space or velocity. In fact, I believe most metaphysicians now would deny the objective nature of time altogether. It might therefore be useful to accept both position and velocity as fundamental conceptions, and deduce time intervals from them. In any case, sufficient has been said to show that the practical definition of relative motion cannot in itself be taken to prove that absolute motion is an impossible conception.

If I suggested at the outset of this discussion that most of us have all along been secret believers in absolute motion, I was led to that belief partly by the manner in which the problem of solar motion in space has always been treated. Those who have drawn the logical conclusion from the observations have not infrequently guarded themselves by some statement that after all it is only relative motion they are trying to prove. But their discussion nearly always tacitly assumes, not relative, but absolute motion, and I think most astronomers and physicists, if taken unawares, would admit the absolute motion of the solar system in space as a proved fact, though on second thoughts they might try to explain it away by motion relative to the æther or by some other expedient invented *ad hoc* to safeguard their true faith in relative motion.

But a tacit assumption of absolute motion is also included in the definition of force which at present is much in favour. "Force is rate of change of momentum." If velocity is relative, momentum is relative also. The above definition is therefore incomplete, and may be misleading unless it is definitely stated what the standard system is relative to which momentum has to be measured. Even

quite apart from the earth's rotation the force of gravity impelling a body to the ground is not correctly measured by the rate of change of momentum relative to the earth. Though the neglect of the mass of the body itself, compared with that of the earth, may not lead to serious contradictions in this particular instance, the definition is wrong in principle unless absolute momentum be meant, or unless it be specified that the momentum has to be taken relative to some body unacted on by any forces.

For our definition of force we shall have to return to Newton, and I may have to trouble you with a further communication to justify my belief that though modern criticism has been able to point out the weak spots of the Newtonian system, it has failed to substitute any more secure or more logical basis for our foundation of mechanics.

The Diffusion of Solids.

In view of the interest attaching to the vaporisation and diffusion of solids, the following observations may be worthy of record.

On the inside of the case of a silver watch between forty and fifty years old, and opposite the steel pin of the key-hole, a diffused, dark patch, larger than the key-hole itself, was noticed. When a drop of strong hydrochloric acid was placed on the spot, bubbles of gas were evolved, and the colour gradually became lighter, though after ten minutes, when action had apparently ceased, the patch was still plainly marked. On adding a drop of potassium ferrocyanide solution the blue precipitate due to iron was formed. Similar results have been obtained with other old watches. Since it was shown that the iron was not in contact with the silver, the facts indicate that the iron, or possibly some compounds of iron contained in it, vaporises, dissolves in the silver, and penetrates for some distance into the latter by diffusion.

Prof. F. D. Brown has observed an effect of similar nature. On a porcelain writing tablet were notes written in blacklead perhaps forty years ago. While recent writing is easily removed, these marks can no longer be defaced in any way by washing or mere surface scratching, showing that the carbon has penetrated into the porcelain no inconsiderable distance. That this should have taken place in the case of two such refractory solids as carbon and porcelain is all the more remarkable.

Earth Tremors in India.

In connection with the short description of the Kangra earthquake, and the reference to the still greater earthquake of 1897, contained in Nature of March 1, p. 418, it may be of interest to note that, at a distance of about twelve miles from the point that was supposed to be the centre of greatest disturbance in the latter earthquake, tremors were still appreciable, at frequent intervals, in the early part of 1904.

While we were sitting on the verandah of the Government bungalow at Rongmudu, in the Garo Hills, near the point at which the river Somersary changes the direction of its flow from east to south, in the early afternoon of February 10, 1904, my travelling companion, Mr. A. B. Nowell, of Dwarra, Sylhêt, directed my attention to a booming sound like the beating of distant gongs, and at the same time pointed to a glass of water standing on the table in front of us, in which the water was distinctly agitated. The tremor lasted for only ten or fifteen seconds.

Mr. Nowell, who had spent some months of each year in that neighbourhood for several years in succession, informed me that tremors occurred at frequent intervals every day when he first came there, but were getting fainter and less frequent as time went on. Later in the same day he directed my attention to another tremor, but as we were then walking in the jungle I failed to appreciate it. On the following day we travelled many miles southwards, or away from the centre of disturbance, so that I had no further opportunity of observing these phenomena.

Peculiar Ice Formation.

I should like to direct attention to a peculiar ice formation which I have noticed during the last week on the moorland area at this place, and I should be glad to know if this phenomenon has been observed elsewhere.

The moorland here is of considerable extent, and at a height of 1000 feet above the sea level. The rocks on the upper surface are of a brittle shale with outcropping sandstone, and on the lower slopes beds of clay and gravel. On March 2 I noticed the surface of the ground for distances of a hundred yards or more raised to a height of from 1 to 2 inches, and supported by ice pillars, which had evidently grown by addition of water from below the surface. The sensation of walking on these patches was somewhat analogous to that observed when walking upon a good pile carpet. The late snows had all melted, but the surface contained much moisture, and there had been a certain amount of frost the previous night. The time was 9.30 a.m., and as I stood there these ice pillars crackled and fell in such order as to give the surface a honeycombed appearance.

I found on examination all the talus slopes in the gullies of the moorland to be covered with the same ice structure. These ice pillars were not very evident until some of the earth had been cleared away, as a thin layer of earth was held up in a very uniform manner on the top of them. I found them perpendicular to the surface, both on the pathway and upon the inclined surfaces in the gullies. Several hours afterwards, when the heat of the sun's rays had melted the ice pillars, the whole surface presented a honeycombed appearance. I only noticed this to have taken place in those areas void of any vegetation whatever, and where the heat would be quickly radiated into the atmosphere. The whole of these areas is now broken up into a very fine titrated soil; if this tendency to superficial vertical ice thrust is at all general, it appears to me to be a great factor in the disintegration of surface soils.

Cooperation between Scientific Libraries.

In connection with the discussion raised by the note on Dr. Muir's paper (p. 372) and Dr. Bather's letter, it may be of interest to note that the Royal Irish Academy, some five years ago, prepared a classified card-catalogue of the scientific serials accessible in various libraries in Dublin, and it is proposed to keep this up to date through the cooperation of the various librarians. This catalogue is always ready for reference by any member or visitor in the academy's reading-room; and it has been of late years the custom for the library committees of various Dublin institutions to inquire, when a new periodical is proposed, as to its possible previous inclusion in one of the other libraries.

March 10.

Sounding Stones.

With regard to Mr. Tingle's letter in Nature of January 4 (p. 222) on sounding stones, it may interest you to know that I have just seen at Pagan, the former capital of Burma, now in ruins, a large log of fossil (or rather silicified) wood, used as a gong. It emits a clear ringing note when struck, and is used, like all pagoda bells or gongs, to direct the attention of the guardian spirits to the offering about to be presented by the pious Buddhist.

A NEW COUNTY BIRD-BOOK.[1]

A BOOK on the birds of Hampshire and the Isle of Wight fills up a blank in the list of English county avifaunas, and is a particularly interesting instalment of the series. Few, if any, districts in Great Britain surpass this in the attractions it possesses for the field naturalist, its natural features presenting a greater variety than is usually to be found in an area of similar limitations, large though this county is. If it boasted of nothing more than the far-famed New Forest, the happy hunting-ground of so many naturalists, Hampshire would furnish material for a good bird-book. But in addition to its woodlands it embraces open downland and hills, cultivated country and a varied coast-line including the muddy estuaries and harbours of the mainland and the famous cliffs of the "Island." It is not, therefore, surprising to find the district credited with a list of 127 resident birds and summer visitors, which remain to breed, in addition to 70 winter visitors, 36 occasional visitors, and 61 species of so rare occurrence that the authors are obliged to attribute their appearance to accident. With regard to the occurrence of rare visitors on migration, the authors point out that the lighthouses and vessels (to which are due the discovery of so many waifs) on this coast are not good stations for observation.

Hampshire has not been less fortunate in her naturalists and her natural historians than in her natural features. From the days of Gilbert White onwards the birds of Hampshire have been studied and loved by many notable people. Hardly less known than the "Natural History of Selborne," we have the immortal "Instructions to Young Sportsmen" of Colonel Peter Hawker, and his more recently published "Diary"; Gilpin's "Forest Scenery" and Wise's "History of the New Forest." These, added to the writings on local birds of the Rev. C. Bury, Captain Henry Hadfield, Prof. T. Bell, Mr. A. G. More, the Rev. Richard Warner, Mr. G. B. Corbin, Mr. E. G. B. Meade-Waldo, and others, have furnished the authors with a wealth of material stretching back to a time when little attention was paid to ornithology. But besides these more pronounced naturalists, famous men of letters, and women, too, have made some mention of Hampshire birds—Kingsley and Tennyson, and Jane Austen and Charlotte Yonge—while the modern maker of books has not left them alone.

In collections, too, the county is rich, and that of Mr. E. Hart (without whose assistance no history of Hampshire birds could be complete) at once suggests itself as of preeminent importance. The strictly local collection at Heron Court contains many historical specimens, while the eggs owned by Dr. Rake are of exceptional interest, many of them being referred to in Wise's "History of the New Forest." The work has been excellently planned and carried out. With such a wealth of historical facts available the authors proposed not only to deal with the birds as they exist at this moment, but to trace their history in the writings of those who have gone before them. The "Natural History of Selborne" forms the backbone of the work, and we have here for the first time what White has to say (not only in his book, but also in his still unpublished "Journal of Observations") about the birds of Selborne arranged in scientific order.

Of the more interesting species the authors have given very extended notices, and of all these the honey buzzard is the most important, on account of its having been found in former years more commonly in this county than in any other part of England. Among other birds of which valuable accounts are given may be mentioned the raven, buzzard, hobby, Montagu's harrier, cirl bunting, hoopoe, and great bustard. The breed of peregrines for which the Isle of Wight was famous in the old days of hawking still keeps a footing there; and to turn from decreasing species, it is pleasant to read that the redshank is increasing as a resident; that White's "clamouring" favourite, the stone curlew, is happily still plentiful, and that the woodcock, shoveller, and tufted duck are becoming more numerous as breeding species. But whether the great increase in numbers of the black-headed gull will prove an unmixed blessing is perhaps open to doubt.

FIG. 1.—Black-headed Gull. From "The Birds of Hampshire and the Isle of Wight." From a photograph by Mr. Smith Whiting.

A curious account is given of some merlins breeding in Hampshire in the early 'sixties. The nests, which were stated to have been found in such previously unheard-of situations as pollard hollies, and holes in yew and beech trees, contained three eggs in each instance. We should certainly have been inclined to refer these eggs to the kestrel had not the male bird been shot from the nest in one instance, and had not its skin, together with the eggs, been

still in existence. An interesting introduction closes with an account of the laws applying to local birds; and the volume is embellished with a map of the district, four drawings by Mr. G. E. Lodge, and reproductions of some most beautiful photographs of birds by Mr. Smith Whiting, one of which we are enabled to reproduce. O. V. APLIN.

THE ADULTERATION OF BUTTER.

DURING the last few years much unscrupulous ingenuity has been applied to the sophistication of butter. Both on the Continent and in this country the adulteration of this, the best of edible fats, has developed into quite an industry, having its own factories and its own chemists, and conducting its operations on a scale which, for a furtive, dishonest business, is really of remarkable magnitude. Considerable profits are alleged to be made, and it is therefore not surprising that the traffic has flourished in spite of all attempts at suppression. Perhaps it may be of interest to those readers of NATURE who are not chemists to have placed before them, with as little technicality as may be, a sketch of the modern methods of butter-adulteration, and of the means adopted or suggested to checkmate this form of fraud. The importance of the matter both to the consumer and the agriculturist may be pleaded as a justification for discussing the question at some little length.

Butter, though consisting essentially of the fat of milk, is always associated during manufacture with more or less water, the quantity of which ranges generally from 7 to 15 per cent. One of the simplest forms of adulteration consists in working an excessive proportion of water into the butter. To check this is comparatively easy; a maximum limit of 16 per cent. has been fixed by the Board of Agriculture, and persons dealing in butter containing more water than this are liable to prosecution.

There exists, however, an insidious variant of this water-logging in the production of what is called "milk-blended" butter. In preparing this, skim milk, costing about a penny per gallon, is largely used. It may either furnish curd to be incorporated with the butter, or, after a little "ripening" with micro-organisms to improve the flavour, it may be used for direct admixture. By working up butter with such milk a product may be obtained containing 25 to 30 per cent. of water, as well as a substantial quantity of curd. The proportion of butter-fat in such a mixture will often be less than 65 per cent., whereas ordinary butter contains from 80 to 90 per cent. Yet the sale of the article is not, legally, a fraudulent transaction, provided the substance is sold as "milk-blended" butter, and not simply as "butter." At first sight this may seem reasonable enough; the purchaser is told what he is buying, and for the rest—well, *caveat emptor*. But, after all, some regard should be had to attendant circumstances. It is the poor who chiefly consume the manipulated butter, and neither they, nor, indeed, any ordinary purchaser, would realise that the fat-value of the blended article is only about three-fourths of that of genuine butter. Of course, if the price is correspondingly lower there is no fraud. But the contention of those who oppose the sale is that there is always a substantial margin of unfair profit; "milk-blending," in fact, is held to be essentially a device for supplying an excessive proportion of water, relative to the amount of fat, without incurring the penalties provided for infringement of the Sale of Butter Regulations.

Be this as it may, a measure to prohibit the use of the word "butter" for such mixtures, on the ground that it is a misleading description, was brought forward two or three sessions ago, only to be sacrificed to the exigencies of politics. It remains to be seen whether a better fate is in store for it under the new Administration.

Perhaps, however, the most frequent, and certainly the most troublesome, sophistication of butter consists in the admixture with it of fat other than that of milk. There are two chief adulterants of this class now in use. One is a soft fat obtained from beef-suet by removal of the harder "stearin" portions; this fat may sometimes be mixed with or replaced by lard, and is generally churned up with water (or with milk) to facilitate the subsequent "blending." The other adulterant is a refined cocoa-nut "oil" or fat, purified so as to be practically tasteless. These substances, supplied at about half the price of butter, are variously known as "mixing article," "enricher cream," "neutral fat," or "neutral blending," and are carefully prepared to simulate butter in consistency. A still more subtle adulterant is formed by a judicious mixture of the two, which yields analytical figures identical in some respects with those of genuine butter. Let us examine this a little more closely.

Chemically, butter-fat consists of a mixture of glycerides—that is to say, compounds of fatty acids with glycerin. For instance, one such glyceride may, with sufficient accuracy for our present purpose, be represented as the following combination:—

$$\text{Glycerin}\begin{cases}\text{Oleic acid}\\ \text{Palmitic acid}\\ \text{Butyric acid}\end{cases}\textit{minus}\ \text{water.}$$

When these acids are freed from their chemical union with the glycerin, the butyric acid is found to be sharply distinguished from the other two by the fact that it is soluble in water and volatile on distillation with steam. Now the chief difference between butter-fat and other fats lies in the comparatively high proportion of butyric acid (and similar volatile acids) which the butter-fat contains. The following summary represents the composition of a specimen of the prepared beef-fat and of two samples of butter-fat:—

	Prepared beef-fat	Butter-fat No. 1	Butter-fat No. 2
	Per cent.	Per cent.	Per cent.
Volatile or soluble acids	Practically nil	5·0	6·7
Insoluble acids	95·5	90·0	88·0
Glycerin	10·9	12·1	12·7
	106·4	107·1	107·4
Less combined water	6·4	7·1	7·4
	100·0	100·0	100·0

Like other natural products, the fat of milk varies in the proportions of its components, and the two samples here quoted show the range of variation met with in ordinary butter. Analytically, No. 1 is butter of low quality; No. 2, on the other hand, is above the average. The difference consists, as will be seen, in No. 1 containing less volatile acids, less glycerin, and more insoluble acids than No. 2. These are precisely the directions in which beef-fat differs from butter-fat. Broadly, one may say that, analytically, the first specimen of butter has more of a beef-fat character than the second.

This is the point which the adulterator seizes upon. "If," he argues, "I start with butter No. 2, I can add to it quite a considerable quantity of my prepared beef-fat before the mixture shows a smaller percentage of volatile acids than butter No. 1 contains; and since No. 1 is perfectly genuine butter, it is difficult to see how any analyst will be able to swear that my mixture is not also genuine butter." Indeed, the analyst often finds it no easy matter to expose the

fraud. If butter had always the same composition the matter would be simple enough. It is the natural variation, small though it be, which has hitherto enabled the sophisticator to pocket his ill-gotten fortune.

This variation arises from a number of causes, of which some at least have been fairly well elucidated. In the main it is due to differences in the feeding and treatment of the cows. For instance, Dr. J. J. L. van Rijn showed some years ago in Holland that with the approach of winter, when grass was becoming poorer and less plentiful, and cows, kept late in pasture, were much exposed to cold, the proportion of volatile acids in the butter became abnormally low; but that as soon as the animals were stabled, and therefore better fed and protected from inclement weather, the volatile acids began to increase. To treat the cows more generously in the matters of warmth and provender was thus the remedy for the abnormality indicated. Nevertheless, there still remain some minor causes of variation, such, for instance, as the different physiological conditions of the cows in varying stages of lactation. The effects of these, however, are largely neutralised when we deal with butter made from the mixed milk of many cows; though they have to be taken into account where nothing is known about the history of a particular specimen of butter.

What, then, it may be asked, are the means by which any check at all can be placed upon the sophistication? Having regard to the variation in admittedly genuine samples, is not analysis useless except in very gross cases of fraud? By no means. Let us see what it can do, and how it may be supplemented.

In his search for adulterants the analyst may determine the following constants of the butter-fat he is examining:—(1) Its specific gravity: in butter this is higher than in beef-fat, but lower than in cocoa-nut oil; (2) its refractive index: this again is intermediate in value between those of the two adulterants mentioned; (3) its "saponification" value, which gives a measure of the total quantity of fatty acids and also of the glycerin; and (4) most important of all, the proportion of volatile acids. So far as concerns butter, these physical and chemical data are all correlated with the fact that glycerides of the volatile acids form a relatively large proportion of the genuine fat. They are therefore correlated with one another, and, within limits, are interdependent. The more volatile acid there is, the greater is the specific gravity and the higher the saponification value, whilst the refraction alters inversely. There is thus a kind of parallelism preserved among the constants of genuine butter, notwithstanding the variations in their absolute values. For instance, given genuine butter-fat such as that already referred to as "No. 2," with 6.7 per cent. of volatile acids, one can predict with confidence that its specific gravity will be pretty close to 0.9130 (37°.8 C.), and its saponification value not much different from 232. On the other hand, if the butter-fat contains, like No. 1, only 5 per cent. of volatile acids, we can say with equal confidence that its specific gravity will be about 0.9105, and its saponification value approximately 222.

Suppose, now, an adulterator mixes cocoa-nut oil with the first of these butters until he has reduced the volatile acids from 6.7 per cent. to 5 per cent., the quantity in the second butter. Such an admixture would easily be detected, notwithstanding the fact that the volatile acids correspond in quantity with those of genuine butter. For one thing, these acids can be further examined and made to yield evidence of the admixture; and for another, the addition of the cocoa-nut oil has destroyed the parallelism referred to; the figures are now quite inconsistent with one another, and the sophistication is readily demonstrable. Speaking generally, with a sufficiently extended analysis there is no particular difficulty in detecting relatively small quantities of cocoa-nut oil in butter. But a mere determination of the proportion of volatile acids will not suffice—which explains, perhaps, why this special form of fraud has enjoyed a rather longer life than it might otherwise have had.

The addition of beef-fat or lard is somewhat more difficult to prove. Reliance has chiefly, though not entirely, been placed upon the consequent diminution of the volatile acids. Unfortunately, the natural variation of these in genuine butter is rather considerable, as has been pointed out. Yet even so, it does not follow that the lowest known limit for volatile acids must be taken as the criterion in forming a judgment. There are often collateral circumstances which narrow the range of admissible variation. For instance, a large consignment of "creamery" butter must necessarily, under ordinary commercial conditions, be a product of the mixed milk of many cows, and hence the proportion of volatile acids must tend towards the average value. The minimum quantity, which in exceptional circumstances milk-fat from a single cow might admittedly show, is here lost in the general mean. No weight need be given to it in judging the genuineness of the butter. Similarly, samples purporting to be butter produced in the summer or winter months cannot claim to be judged by the low minimum sometimes found in autumn butter. Again, it may be known, from systematic analyses of genuine butter produced in a certain region, and sampled in circumstances which guarantee the representative character of the samples, that the butter of this region in a specified month did not, as a fact, fall below a particular value in the matter of volatile acids. By having regard to these and similar considerations, as well as to the actual analytical figures, it has been possible in many cases where butter adulterated with beef-fat or lard had been imported into this country from the Continent, not only to prove the fact of the adulteration, but to form a fairly close estimate of its amount.

Some check has thus been placed upon the fraud in question. Yet, although the means at disposal will serve to discover the more considerable amounts of adulteration, there is still a residuum of cases which are either doubtful or in which the legal proof is difficult by reason of the clever way in which advantage has been taken of the natural variation in the constants of butter. To deal with these cases other means are required in supplement of the chemist's work. In Denmark, for instance, there is official supervision of the butter industry; and in Holland the Government has organised an admirable system of State "control," whereby the official *imprimatur* is accorded to butter produced in factories under the Government inspection. Joining the "control," however, is at present a voluntary matter, and for factories not under it, and which may be suspected of malpractices, a compulsory and more rigid system of inspection has been proposed. In this country a considerable amount of falsification has been going on. Enterprising and unscrupulous individuals import or manufacture the adulterants mentioned above, and offer, in consideration of a substantial fee, to initiate the proprietors of butter-blending factories into the whole art and mystery of butter-"faking." As regards the suppression of this, the Customs authorities in the first instance endeavour to secure that all importations of adulterants coming within the legal definition of margarine shall be marked accordingly,

in order that their destination may be the better traced. Further, the traffic in the finished mixture has been somewhat checked by a number of prosecutions, undertaken by Government in the case of imported products, and by a few local authorities in cases where the "blended" butter was sold in this country. But to kill the snake instead of merely scotching it additional weapons are required. Useful measures for this purpose would be: (1) To adopt a recommendation made by a departmental committee some years ago, that a minimal limit for volatile acids should be fixed, below which a presumption should be raised that the butter is not genuine; this would strengthen the hands of the public analyst, and though it would not altogether stop the adulteration, it would restrict its amount and diminish the profits accruing therefrom. (2) To enact that no substance shall be sold as butter if it contains less than 80 per cent. of butter fat; this would prevent the "loading" of butter with curd or "solidified milk." (3) To organise a system of strict inspection of butter factories. (4) To give the Commissioners of Customs greater powers for regulating the admission into this country of adulterated butter and of substances which may be used in the adulteration of butter. (5) Most effective of all would be for the Government of each butter-exporting country to adopt some system modelled on the Netherlands "control" plan of combined inspection and analysis, and to furnish an official voucher of purity, without which the butter would either not be admitted here at all, or only under special conditions of marking. For this, however, we shall have to wait.

C. Simmonds.

A REMARKABLE DISCOVERY IN EGYPT.

On February 7 a most important discovery was made by Prof. Naville at Thebes. The excavation of the eleventh dynasty temple at Deir el-Bahari, discovered by Prof. Naville and Mr. H. R. Hall, of the British Museum, in 1903, has since been carried on for the Egypt Exploration Fund by these gentlemen, assisted by Mr. E. R. Ayrton. Mr. Ayrton being unable to continue working for the Fund this year, his place was taken by another of the Fund's excavators, Mr. C. T. Currelly, who joined the expedition for the first time this year. During this season work was first carried on by Messrs. Hall and Currelly in the southern court of the temple. Here were discovered some interesting priests' houses (?) of brick, dating from the time of the twelfth to eighteenth dynasties, and the south temenos-wall of the temple. This wall was found to be of the same type as the south wall of the great temple of Queen Hatshepsu, which was thus shown to be in reality the north temenos-wall of the eleventh dynasty temple. Later on Mr. Hall began the excavation of the back part of the temple to see how it ended. He discovered, Prof. Naville says, "the enclosure wall and found that the enclosure was interrupted by a court or wide avenue, lined on both sides by a single row of columns, and directed towards the mountain. The rock had been cut open to make way for the avenue."

Later on, when Prof. Naville reached Thebes and Mr. Hall left for England, work was directed to the exploration of the remains of an eighteenth dynasty building, also in the back part of the temple, which had been discovered by Messrs. Hall and Ayrton in 1904. At the end of this building was made Prof. Naville's splendid discovery, described by him in the *Times* recently. It consists of a cell or chapel excavated in the rock, lined with coloured relief sculptures depicting King Thothmes III. making offerings to the god Amen, and in the midst of it was found intact the original cult-image, a great painted and gilded stone cow, of life size. The cow was the emblem of Hathor, goddess of the western deserthills, who was specially venerated at Deir el-Bahari. The image was dedicated by King Amenhetep II., the son and successor of Thothmes III. The chapel belongs really, not to the eleventh dynasty temple, although placed at the end of it, but to the great temple of Deir el-Bahari, with which it is contemporary. The great interest of the figure of the cow, besides its importance as a work of art, lies in the fact that this is the first time that an Egyptian cult-image has been found intact in its shrine. The whole chapel and image will be re-erected in the Museum of Cairo. Illustrations of the find were published in the *Graphic* and *Daily Graphic* of March 2.

This discovery is the latest proof of the remarkable nature of Prof. Naville's work for the Egypt Exploration Fund at Deir el-Bahari, which is one of the most interesting sites for archæological work in Egypt, and one of the most productive of interesting small antiquities, chiefly votive offerings to Hathor of the time of the eighteenth dynasty. These often are in the shape of little cows of blue glazed faïence, models of the great cult-images in the various cave-shrines of Hathor, of which the newly discovered chapel is one, the chief being the well known Hathor-shrine, with the red painted reliefs, on the platform of the great temple, found by Mariette many years ago.

The work of the Egypt Exploration Fund, which is now being carried on by Prof. Naville and his assistants alone, needs considerably more monetary support than is at present being extended to it. It is to be hoped that this discovery will act as an incentive to those who are really scientifically interested in the progress of archæological knowledge, no matter by what *person* that progress is effected, to give their help to the Egypt Exploration Fund, which discovered Naukratis and the store-city of Pithom, identified the route of the Exodus, excavated Tanis, Bubastis, and Herakleopolis, scientifically explored the tombs of the most ancient kings at Abydos, and is now bringing successfully to an end its most imposing work, the excavation of the two temples of Deir el-Bahari at Thebes.

NOTES.

The Bakerian lecture of the Royal Society will be delivered by Prof. John Milne, F.R.S., on Thursday next, March 22, on "Recent Advances in Seismology."

Prof. O. Hertwig, professor of comparative anatomy, University of Berlin, and Prof. H. O. Osborn, professor of zoology, Columbia University, New York, have been elected foreign members of the Linnean Society.

The annual general meeting of the Chemical Society will be held on Friday, March 30, when the president will deliver his address, entitled "The Living Organism as a Chemical Agency: a Review of some of the Problems of Photosynthesis by Growing Plants."

An unprecedented mining disaster occurred on March 10 at the Courrières colliery in the department of the Pas de Calais. An explosion of fire-damp resulted in the loss of more than 1100 lives. The causes of the explosion have not yet been fully established. The colliery employed 6998 persons, and possesses forty-four seams of coal; the annual output is about 2,000,000 tons. In 1890 attention was directed to this colliery by Sir C. Le Neve Foster on account of the remarkably low death-rate from falls of ground, and it was reported upon by a deputation of H.M. Inspectors of Mines. The average death-rate from

falls of ground per million tons of coal raised in the period 1890 to 1899 in Great Britain was 2·16, whilst at Courrières it was 0·39. The colliery was certainly admirably managed, and this fact makes it difficult to account for the terrible explosion, the immediate cause of which appears to have been an underground fire.

WEATHER of a very wintry type has been experienced this week over the British Islands, and in places the cold has been unusually severe for the time of year. On Sunday a large and important storm area arrived from the Atlantic, and in the course of the day its centre traversed Scotland. As the storm was approaching, strong westerly winds and gales, with heavy rains, were experienced generally. The storm developed considerable energy after reaching the North Sea, the barometer falling as low as 28·4 inches, and in the rear of the disturbance the wind greatly increased from the northward. Strong northerly gales accompanied by heavy squalls of snow or hail were experienced on Monday over nearly the entire country, and the storm occurring at the time of spring tides caused severe floods, especially along our east coast. The German and Dutch coasts have also suffered greatly. Sharp frost was experienced in Scotland and over the northern parts of England.

CANON TRISTRAM, F.R.S., whose death, at the age of eighty-three, took place on March 8, is believed to have been the first zoologist to make special application of the theory of natural selection. This he did in an article on the "Ornithology of Northern Africa," published in the then newly established journal the *Ibis* for October, 1859 (vol. i., pp. 429–433), and before the appearance of the "Origin of Species," grounding his belief solely on the papers communicated to the Linnean Society on July 1, 1858, by Messrs. Darwin and Wallace (Journ. Proc. Linn. Soc., iii., Zoology, pp. 45–62). "Writing," he said, "with a series of about 100 Larks of various species before me, I cannot help feeling convinced of the truth of the views set forth" in those communications. "It is hardly possible, I should think, to illustrate this theory better than by the Larks and Chats of North Africa." There is no room here to reproduce the next three pages, but they are worth reading now if only as recording an early and full acceptance of the Darwinian doctrine, and whether so much courage was shown by anyone elsewhere seems very doubtful.

MR. HALDANE, Secretary of State for War, in making the customary annual statement as to the policy of the Army in the current year, delivered a speech which has been received with much satisfaction in the scientific world. The need for clear thinking and for the application of the methods of science to the affairs of State was recognised frankly and emphasised repeatedly. Mr. Haldane's encouraging words to the military experts of to-day, his definition of the science of military organisation, and his description of a new school of young officers—as much men of science as engineers or chemists—should serve to inspire Army men with the spirit that must actuate successful practice. The Secretary for War assured the nation that our officers are becoming men with scientific training and reflective minds, and there is every hope they will soon work in connection with a thinking department such as that which took so prominent a part in securing the recent Japanese success. It is fortunate for this country that the Secretary for War believes in the application of scientific knowledge to military affairs, and we look forward to the time when this need for scientific thought will be recognised in every branch of the public service.

THE correspondence on the cause of the loss of the coal-tar colour industry, which is represented in Germany by a capital of 5,000,000*l*., with an annual value of about 50,000*l*., and the prospect of other industries passing out of our hands in the same way, continues in the columns of the *Times*. The writer whose article upon the jubilee of Dr. Perkin's discovery gave rise to the correspondence states in the issue of March 10 that in the early days of the coal-tar industry there were not a few accomplished chemists in England, but they could not find employment in the colour factories; and this being the case, the schools naturally felt discouraged in their efforts to produce men specially qualified for such work. "Our methods of policy," he remarks, "must be very different from those adopted in the past if we are to succeed; complete sympathy must be established between science and industry." The meaning and value of research have yet to be understood by the commercial community and the manufacturers of this country; and it is still necessary to impress upon the nation that scientific method is an essential factor of the development of industries. When there is a scientific laboratory in every works, the National Physical Laboratory will be able to take its proper place in a national scheme for the promotion of progress of applied science.

THE death of Mr. J. G. Goodchild removes a geologist and naturalist whose knowledge covered an unusually wide range, including ornithology, glacial geology, physical geology, and mineralogy, in all of which he did useful work, thanks to his thoroughness in testing generally accepted explanations, his independent originality, his keen insight, and his artistic skill. Mr. Goodchild served for more than thirty years on the staff of the Geological Survey, being especially engaged in Westmorland and Cumberland, of which counties he made a comprehensive study. While in London, in the winters, he was for some years a valued worker at Toynbee Hall, living beside it in a Whitechapel tenement, and devoting most of his evenings to the organisation of its science classes. For the past fifteen years he was in charge of the geological and mineralogical collections belonging to the Geological Survey in the Edinburgh Museum, and, in connection with his work there, he edited Heddle's "Mineralogy of Scotland," and prepared a careful monograph on the Scotch zeolites. He was also lecturer in mineralogy and geology at the Heriot Watt College. His most important scientific contribution was his paper on the glacial deposits of the Eden Valley, published by the Geological Society in 1875; it will doubtless rank as one of the classics of British glacial geology, though its influence suffered by its publication fifteen years before the original views there expressed could be correctly appreciated.

THE annual meeting of the Royal Society for the Protection of Birds will be held on March 20. The chair will be taken by the Marquess of Granby, G.C.B.

A REUTER message from Lahore, dated March 10, reports that a severe earthquake has occurred in Bashahr, one of the hill States.

THE Berlin correspondent of the *Times* states that Prof. Koch delivered an address on March 7 at the Kaiser Wilhelms Akademie, in the presence of the German Emperor, on the subject of his investigations into the causes and nature of the sleeping sickness in Uganda and East Africa. His studies, he stated, have entirely confirmed the results of the investigations of Dr. Castellani and Col. Bruce, and he has devoted his efforts in particular to investigating the habits of *Glossina palpalis*, the fly by which the infection is conveyed.

It has been decided to found an International Association of Colonial Agronomy to promote the scientific study of the problems of colonial and tropical agriculture and of the commercial utilisation of natural products. The headquarters of the organisation will be in Paris. The project took shape at the last meeting of the French Association of Colonial Agriculture and Colonisation, when a provisional committee was appointed to organise the International Association, with M. de Lanessan as president and the following vice-presidents:—Great Britain is represented by Prof. Wyndham Dunstan, F.R.S.; Germany, by Prof. Warburg; Brazil, by M. de Piza, Brazilian Minister in Paris; Italy, by Count Sabini; Mexico, by M. de Mier; Holland, by Prof. Greshoff; Portugal, by Prof. Batalha Reis; while France is represented by M. Myre de Vilers, president of the French Geographical Society, Profs. Giard, Müntz, Prillieux and Roux, and MM. Henrique, Tisserand, M. Dybowski, of the French Colonial Office, and Prof. Heim. The first meeting of this committee of initiation will be held this month in Paris.

On Tuesday next, March 20, Dr. J. E. Marr, F.R.S., will deliver the first of three lectures at the Royal Institution on "The Influence of Geology on Scenery." These are the Tyndall lectures; and on Thursday, March 29, Prof. Bertram Hopkinson will begin a course of three lectures on "Internal Combustion Engines," with experimental illustrations. The Friday evening discourse on March 23 will be delivered by Lord Roberts, on "Imperial Defence"; on March 30 by Prof. Zeeman, on "Recent Progress in Magneto Optics"; and on April 6 by Mr. W. B. Hardy, on "The Physical Basis of Life."

From the Egyptian Survey Department we have received a copy of a "Catalogue of the Geological Museum, Cairo," compiled by Dr. W. F. Hume.

In part vi. of vol. xix. of the Proceedings of the Geologists' Association Mr. M. A. C. Hinton describes the horn-core of a ruminant from the Norwich Crag of Bramerton as representing a new species of gazelle, under the name of *Gazella daviesi.*

The eyes of deep-sea animals form the subject of an instructive article, by Dr. O. Rabes, of Magdeburg, in the February number of *Himmel und Erde.* Special attention is directed to the strange larval fish recently obtained during the *Valdivia* expedition in the Antarctic, and also in deep water in the Indian Ocean, and described under the name of *Stylophthalmus paradoxus.* In this creature, the systematic position of which is uncertain, the eyes are mounted, crab-fashion, on stalks, the length of which apparently varies according to age.

The modern practice of supplying hives of bees with new queens at comparatively short intervals renders it essential that a sufficient stock of queen-bees should always be available at a moderate cost to the hive-owner. In America it appears that there are establishments specially devoted to the rearing of queens for sale; but as the price charged is considerable, the entomological section of the Department of Agriculture has issued a Bulletin (No. 55) in which the author, Dr. E. F. Phillips, gives full instructions to enable the hive-owner to breed his own queens.

The mode in which the American prongbuck, or "antelope," protects its young forms the subject of a beautifully illustrated article, by Mr. H. H. Cross, in the March number of the *Century Illustrated Magazine.* According to the author, the female prongbuck, when about to give birth to offspring, proceeds to the middle of one of the numerous patches of cactus occurring in the haunts of these animals, and there, by means of a series of bounds in the descent from which the cactuses are cut to pieces by her sharp hoofs, clears a space in the centre. Here the young are born, and remain for some time, secure from wolves, which are unable to penetrate the cactus-fence. Danger is, however, experienced from eagles, and to protect their young from these birds the antelope are stated to display great courage.

The February issue of the *Quarterly Journal of Microscopical Science*, which completes the forty-ninth volume, contains five articles, all devoted to invertebrates, and all of a highly technical nature. The most generally interesting, perhaps, is one by Mr. D. H. Tennent on a cercarian parasite, *Bucephalus haimeanus,* infesting oysters in America, more especially those growing in brackish water. Mr. W. Woodland continues his investigations into the mode of formation of spicules, dealing in this instance with those of the Cucumariæ, and the "plate-and-anchor" type characteristic of Synapta. The maturation of unfertilised eggs of sawflies is discussed by Mr. L. Doncaster, while Prof. J. E. Duerden endeavours to explain the *rôle* of mucus in his favourite corals, and Mr. W. S. Perrin records observations on the structure and life-history of *Pleistophora periplanetae,* a sporozoan parasite of the cockroach.

Miss Harriet Richardson has prepared a "Monograph on the Isopods of North America," recently published as Bulletin No. 54 of the United States National Museum (pp. liii+727). This work contains careful analytical keys of the families, genera, and species, and a short descriptive account of each species illustrated by text figures of their essential systematic features. The author has evidently spared neither pains nor labour to make her monograph complete, with the result that it must be regarded as an essential part of the outfit of every zoologist who takes an interest in the systematic study of this group of animals.

Tuberculosis in cattle, by Mr. John M. Scott, is the subject dealt with in Bulletin No. 55 of the New Mexico College of Agriculture. Tuberculosis is defined, the extent of the disease, symptoms, and modes of infection are described, and the use of tuberculin is detailed. The Bulletin is illustrated with five capital plates.

A short part continuing the work of the late Mr. G. S. Jenman on the descriptions of West Indian and Guiana ferns has been published. This and future parts will be based on Mr. Jenman's manuscript, and it is anticipated that the work can be carried to completion. In this part the genus Lomaria, containing eight indigenous species, is described.

A department of forestry has been instituted in connection with the South African College, Cape Town. Provision is being made for ten resident students at Tokai, where the arboretum, a forest museum, and other advantages will furnish excellent facilities for the practical work. The curriculum will consist of a preliminary scientific course in the first year, followed by a two years' forestry course.

A bulletin, No. 52, on the agathi plant, issued by the Department of Agriculture, Madras, deals with the cultivation of this plant, *Sesbania grandiflora*, as a support for the betel-vine, the leaves of which form one of the ingredients of the masticatory *pán-sopári.* The agathi plants are topped to prevent them growing too high; the branches

are fed to cattle or used as a green manure for the betel-vines, and the tender leaves and young pods are served as a curry.

In the January number of the Bulletin of the Department of Agriculture, Jamaica, Mr. W. Harris refers the different varieties of yams cultivated in the island to four species, *Dioscorea sativa*, or negro yam; *Dioscorea alata*, or white yam; *Dioscorea cayennensis*, the yellow or afou yam; and *Dioscorea trifida*, the Indian yam or cush-cush. For the destruction of cotton worm and cassava caterpillar, where Paris green is likely to injure the foliage, or when it may be washed off by rain, Mr. W. Fawcett recommends a wash of lead arsenate.

The committee entrusted by the Hawaiian Sugar Planters' Association with the control of the experiment station at Honolulu notifies in its report for the year ending September 30, 1905, that a division of pathology and physiology has been formed under the directorship of Dr. N. A. Cobb, in addition to the division of agriculture and chemistry and a division of entomology. The work of the last named has been chiefly devoted to the study and breeding of insects that prey upon cane leaf-hoppers. Among the bulletins prepared by the agricultural division, the most important presents a review of fertiliser experiments extending over eight years. A bulletin on the inspection and disinfection of cane cuttings is the first publication of the new department. The methods of preparing Bordeaux mixture are discussed, and suggestions are made for treating cuttings on a large scale.

In the *Engineering and Mining Journal* (vol. lxxxi., No. 7) is the first authoritative statement of the discoveries in a new gold field at Manhattan, in Nevada, which is at present attracting much attention. The veins, which appear to be extraordinarily rich in gold, occur in limestone in the vicinity of rhyolite.

The preliminary returns issued by the Home Office show that the production of coal in Great Britain in 1905 amounted to 236,111,150 tons, or 3,699,366 tons more than in 1904. The number of persons employed at mines under the Coal Mines Regulation Act was 858,373, or 1·28 per cent. more than in 1904. The production of copper ore was 7115 tons, that of lead ore 27,482 tons, and that of zinc ore 23,647 tons. Statistics of the production from open workings are not yet available, so that details of the production of other minerals are incomplete.

In a paper on the screw propeller controversy published in the Transactions of the Institution of Engineers and Shipbuilders in Scotland (vol. xlix., part iv.), Mr. James Holden endeavours to demonstrate the true action of the propeller, and to show that Rankine's theory is wholly erroneous. He considers that none of those writers who have adopted the Rankine theory, in whole or in part, are able to guide others, either scientifically or practically, in the construction or use of screw propellers.

The latest addition to technical periodical literature is a bi-monthly journal entitled *Concrete and Constructional Engineering*. It has been founded with the object of meeting the growing demand for information regarding concrete and reinforced concrete. The first issue (March) covers 74 octavo pages, and is admirably illustrated. It contains articles by Lieut.-Colonel J. Winn, on the advent of the concrete age; by Mr. W. N. Twelvetrees, on steel skeleton construction; by Mr. C. F. Marsh, on reinforced concrete foundations of buildings; by Mr. C. H. Desch, on the setting of Portland cement; by Mr. B. H. Thwaite, on the preservation of iron and steel against corrosion; and a digest of recent publications on concrete and constructional engineering.

In the Journal of the Franklin Institute of Philadelphia (vol. clxi., No. 2) Mr. E. Keller describes and illustrates a number of improved methods and apparatus introduced in the newly equipped assay laboratory of the Anaconda Copper Mining Co. in Baltimore. The chief duty of the laboratory is to determine the values of copper, silver, and gold in crude copper, and the equipment is probably superior to any elsewhere. Stirring and filtering are effected by machines, and in assaying operations everything is handled in sets. Much labour has been saved, breakage of expensive glass-ware has been very largely eliminated, and the time of the furnace work and the consumption of gas have been much reduced.

The modern locomotive question is chiefly one of boilers. The great increase in the size of boilers and in the pressures carried, which has taken place during the past few years, has necessitated the re-consideration of the principles of design, which had been settled with comparatively small boilers carrying low pressures. The paper on large locomotive boilers read by Mr. G. J. Churchward before the Institution of Mechanical Engineers on February 16 is therefore opportune. He gives illustrations of various locomotive boilers, and shows how much more heating surface is now provided for a given area of cylinder than was formerly considered necessary. The higher pressures now common have undoubtedly produced much more efficient locomotives, both in respect of hauling power and of coal consumption. The improvement has been very marked with every increment of pressure right up to 227 lb. carried by the new De Glehn compound locomotives of the Great Western Railway.

The report of the superintendent of the Meteorological Department of Ceylon for the year 1904 shows that 1904 must be reckoned as one of the "dry" years; the rainfall was considerably below the average over the greater portion of the island, especially in the north and west, where deficiencies of 10 to 15 inches were recorded in several districts. In May, however, the excess of rainfall caused destructive floods; in the Kelani Valley alone 124 square miles were covered, involving great loss of property, the water being higher than at any time since 1871. The climate varies considerably in different parts of the island; in the lowlands it is tropical, but in the high parts of the interior it is equal to that of many parts of Europe. The highest shade temperature recorded in 1904 was 99°·8 at Anuradhapura, in May, and the lowest, 28°·2, at Nuwara Eliya, in February; this is the lowest reading on record. Temperatures exceeding 100° have been recorded in some years; the highest on record was 103°·7, at Trincomalee, in May, 1890.

In the February number of the *Bulletin de la Société astronomique de France* MM. Flammarion and Loisel publish the annual summary of the climatology of 1905 as recorded at the Juvisy Observatory. It appears that a notable feature of the atmospheric pressure was its extraordinary irregularity. With the exception of February, March, and July, the mean monthly temperatures were below the normal. October was the coldest recorded in the neighbourhood of Paris since 1757, excepting the October of 1887. In discussing the solar-radiation record, attention is directed to the abnormal cloudiness of 1905 and to its coincidence, in regard to time, with the large number of sun-spots. The writers suggest that the

abnormal rainfall was caused by increased evaporation taking place in the tropics, and connect this, and the cyclones, earthquakes, and volcanic eruptions which took place during the year, with the increased solar activity.

MESSRS. LANDER AND SMITH, of Canterbury, have sent us their catalogue of new meteorological instruments. Mr. Lander has given much attention to the problem of providing satisfactory self-recording instruments at popular prices, and has devised new forms of apparatus for registering wind-force and direction, rainfall, sunshine, air pressure, temperature, and humidity. The advantages of using instruments which will give a continuous record are obvious; the desideratum is, of course, that they shall give trustworthy records. The anemometer appears to be a modification of the well known Dines's pressure tube anemometer, with the addition of an arrangement for recording upon a separate paper the direction of the wind as well as its force. The sunshine recorder is of the photographic type, but, unlike other photographic recorders, it makes use of a clock for controlling the admission of the light, so that the record is for mean time instead of for local apparent time as in all other forms. As an example of the efficient working of the different apparatus, Mr. Lander has sent us some reduced curves, here reproduced, of the sharp and sudden thunderstorm of February 8. They clearly show an abrupt drop in the maximum force of the wind from about forty miles an hour to almost a calm, and an equally sudden shift in direction from W.S.W. to N.W. The barometer, which had been falling steadily all day, rose abruptly a tenth of an inch, with a simultaneous drop of 12° in temperature and a fall of rain (or snow) of about a quarter of an inch in a few minutes. During the storm no less than six windmills were struck by lightning near Canterbury, where the records were obtained.

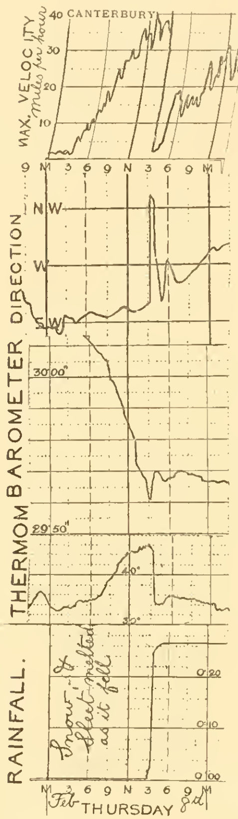

FIG. 1.—Reduced copies of records from self-recording instruments, February 8.

UNDER the title of "An American Laboratory for Experimental Phonetics in Germany," Major H. vom Hagen describes the experiments carried out with the aid of the Carnegie Institution by Prof. E. W. Scripture, first in Munich and later on in Berlin. The paper is illustrated by tracings of phonographic records, and is published in *Prometheus*.

IN the Bulletin of the French Physical Society, No. 235, it is stated that M. Ernest Bichat, who died towards the end of last year, was the author of a number of papers on magnetic rotatory polarisation in gases, and in conjunction with M. Blondlot on oscillating discharges, on Kerr's phenomenon, and on the cylindrical absolute electrometer. He was dean of the faculty of science at Nancy.

A PORTRAIT of Prof. Georg Cantor, of Halle, is published in the January number of the *American Journal of Mathematics*. Cantor's researches on the theory of multitudes and the continuum earned for him the Royal Society's Sylvester medal in 1904, and, speaking of this theory, Dr. Pittard Bullock writes:—"Herr Georg Cantor is looked upon as the discoverer and creator, and in rare cases has a discovery been attributed to one man alone with more readiness." We extract this quotation from a thesis on "The Power of the Continuum." In this thesis Dr. Pittard Bullock gives a proof that the power of the continuum is the lowest but one, or, in other words, that there is no multitude the power of which is lower than that of the continuum but greater than that of a dinumerable multitude.

TWO papers on the vibrations and stresses in shafting have recently appeared. One, forming the fourth of the technical series of the Drapers' Company Research Memoirs, is based on a paper written by Prof. Karl Pearson in 1885, and deals with torsional vibrations treated by Saint Venant's methods; it is illustrated by a large number of lithographed diagrams. The other is a reprint from the Minutes of Proceedings of the Institution of Civil Engineers of a joint paper by Dr. Chree, F.R.S., Captain H. R. Sankey, and Mr. W. E. W. Millington, dealing in the main with the dangers arising from synchronism between the periods of free vibration of the loaded shaft and the periods of fluctuation of the force or torque applied to it. In a large class of practical applications we have to deal with shafts carrying such loads as flywheels, where the kinetic energy of the shaft itself can be neglected, for purposes of rough calculation, in comparison with that of the loads.

IN a paper on the future of statistics, published in the *Statistical Journal* (lxviii., 4), Mr. J. G. Mandello directs attention, among other matters, to the need of organisation in the publication of statistics. The paper deals, in a large measure, with the tendency to chaos resulting from the ever increasing production of printed literature on statistics. It is becoming more and more difficult as time goes on for a busy man to obtain the information which he requires as to the actual state of knowledge in any branch of statistical science, and the mere consulting of voluminous masses of literature more often than not fails to give the inquirer the information which he requires, and, indeed, is not unlikely to end in the re-publication of work already done. Mr. Mandello's remedy is to limit the output of printed matter, and to devote the money thus saved to the establishment of central bureaux where papers of a highly specialised character could be conserved, in typewritten form, for the use of future inquirers, a staff of officials being appointed for the purpose of giving the necessary assistance. A plan of this kind is already working in connection with the Geological Survey of Belgium. Instead of printing maps, which soon become

superseded, they keep large manuscript maps on which the newest details are at once entered, and any specialist can obtain on application a drawn copy of the map of any region, which is naturally quite correct and up to date. A side-issue, which the author does not consider, is whether people would rush into archives with the same eagerness with which they now rush into print, and whether it might be better if they did not.

THE great alteration which occurs in the fluorescence spectrum of sodium vapour when the wave-length of the exciting light is changed is the subject of a brief communication by Prof. R. W. Wood in No. 4 of the *Physikalische Zeitschrift*. Three kinds of monochromatic light, having wave-lengths 5085, 4799, and 4676 respectively, and generated by a cadmium arc lamp of the Heraeus type, were employed in the experiments.

THE lecture delivered by Prof. Emil Fischer before the German Chemical Society on January 6, and having for its subject his recent researches on amino-acids, polypeptides, and the proteids, is published in the current number of the *Berichte* (No. 3). The lecture covers an extraordinarily wide field, and contains a *résumé* of the experimental results obtained during the past five years by Prof. Fischer and his colleagues. A briefer and more general summary of recent work tending towards the synthesis of proteid material is contributed by Prof. Maillard to the *Revue générale des Sciences* for February 15.

IN the Proceedings of the American Academy of Arts and Sciences (vol. xli., No. 19) Messrs. Gilbert N. Lewis and Plumer Wheeler have studied the electrical conductivity of solutions of potassium iodide in liquid iodine. Such solutions are found to conduct electricity as well as the best aqueous solutions, but they present certain interesting anomalies. In dilute solution the molecular conductivity increases linearly with the concentration, rising to a maximum and then falling as the concentration increases; the phenomena show a certain analogy with the deviations from Ostwald's dilution law in aqueous solutions. The temperature coefficient of conductivity is, moreover, negative for dilute solutions, but with increasing concentration it passes through zero and becomes positive.

ALTHOUGH several attempts have been made to prepare selenium iron alums of the type

$$Fe_2(SeO_4)_3,M_2SeO_4,24H_2O,$$

no compound of this group has yet been obtained. In the February number of the *Gazzetta* Dr. Cesare Roncagliolo describes the method by which he has succeeded in preparing the rubidium and cæsium salts,

$$Fe_2(SeO_4)_3,RbSeO_4,24H_2O, \quad Fe_2(SeO_4)_3,CsSeO_4,24H_2O.$$

As anticipated, these salts were found to be isomorphous with the ordinary alums. As the rubidium and cæsium salts melt at about 40° C. and 55° C. respectively, it may be inferred by analogy with the other alums that the corresponding potassium and sodium alums melt below 0° C. If this is the case, an explanation is afforded of the failure hitherto experienced to prepare these salts.

A SIXPENNY edition of Lord Avebury's "Beauties of Nature and the Wonders of the World we Live in" has been published by Messrs. Macmillan and Co., Ltd.

MESSRS. PERCIVAL MARSHALL AND CO. have published, at 3*d*. net, a pamphlet by Mr. A. H. Stanley dealing with "Patents to Inventors." A chapter on patent agents is included.

MESSRS. ARCHIBALD CONSTABLE AND CO., LTD., have published a second edition of Mr. Bertram Blount's "Practical Electro-chemistry," the first issue of which was reviewed at length in NATURE of April 18, 1901 (vol. lxiii., No. 1642). The present edition has been revised and brought up to date. The revision of the section on organic electrochemistry has been done with the assistance of Dr. Mollwo Perkin.

THE twenty-first session of the London Geological Field Class, conducted by Prof. H. G. Seeley, F.R.S., will be opened on Saturday, April 28, by an excursion from Nutfield to Redhill, for the observation of parallel escarpments. In addition to the Saturday afternoon excursions, vacation visits extending over two or three days will be made with the view of examining a Tertiary locality in the Hampshire basin, the Cretaceous rocks of north-west Norfolk, Devizes, or Folkestone; the oolites of Swindon or Cheltenham; and the primary rocks of Clifton, the Mendip Hills, the Welsh border, or Leicestershire. The secretary of the class is Mr. J. W. Jarvis, St. Mark's College, Chelsea, S.W.

A COPY of the report of the Felsted School Scientific Society for the year 1905 has been received. The organisation of the members of the society into four sections has now been in working order for two years, and has led to sound collective work, and in some cases originated good individual practical study. Special encouragement is given to the individual efforts of members. Like most similar organisations, this society is greatly in need of funds to supply necessary instruments, specimens, and apparatus to carry out the observations and other work planned by the directors. Men of science could encourage the voluntary study of science in secondary schools by presenting duplicate specimens and unused instruments to school scientific societies. The report shows that a sustained effort is being made at Felsted School to create active interest in the study of science.

MESSRS. ISENTHAL AND CO. have just issued new catalogues dealing respectively with mercury vapour lamps for all purposes, and with electric heating and cooking appliances. The mercury vapour lamps are at present made in three standard lengths of 18 inches, 26 inches, and 38 inches, so as to utilise fully the various standard voltages from 100 volts to 250 volts. At present the lamps are available only for direct current, though they are recommended for use on alternating current in connection with the Grisson rectifier and electrolytic condenser. The catalogue of heating and cooking apparatus is excellently illustrated, and is divided into two sections. The first includes appliances for domestic purposes and use in hotels and clubs, while the second is concerned with technical apparatus for use in factories and laboratories.

OUR ASTRONOMICAL COLUMN.

COMET 1905*c*.—Giacobini's comet (1905*c*) has now become much fainter, but does not set until some $3\frac{1}{2}$ hours after sunset. A further instalment of Herr Wedemeyer's ephemeris is given below:—

Ephemeris 12h. M.T. Berlin.

1906	α (true) h. m. s.	(δ true) ° '	log r	log Δ	Brightness
Mar. 16	2 45 1	1 49	0·1371	0·2718	0·51
19	2 54 0	2 59			
22	3 2 28	4 5	0·1714	0·3058	0·37
25	3 10 28	5 5			
28	3 18 6	6 1	0·2022	0·3375	0·28
31	3 25 21	6 53			

As will be seen from the ephemeris, the comet is still traversing the constellation Cetus towards Taurus, and

will enter the latter about March 27. On March 21 it will be only about 2m. directly east of α Ceti.

COMET 1906*b*.—The comet discovered by Dr. Kopff will evidently not become an object of popular interest, for it passed perihelion at least two months ago, and is now fading rapidly in brightness.

Below is given a set of elements and part of an ephemeris published by Herr M. Ebell in Circular 86 of the Kiel Centralstelle :—

Elements.

$$T = 1906 \text{ January } 4{\cdot}1289 \text{ Berlin.}$$

$$\left.\begin{aligned} \varpi &= 138^\circ\ 25'{\cdot}1 \\ \Omega &= 328^\circ\ 24'{\cdot}2 \\ i &= 0^\circ\ 53'{\cdot}5 \end{aligned}\right\} 1906{\cdot}0$$

$$\log q = 0{\cdot}03508$$

Ephemeris 12h. M.T. Berlin.

1906	α (h. m. s.)	δ (° ′)	log Δ	Brightness
Mar. 15	11 31 20	+1 57	9·7514	0·54
19	11 30 10	+2 2	9·7842	0·44
23	11 29 17	+2 6	9·8166	0·36
27	11 28 44	+2 9	9·8486	0·29

A set of elements computed from later observed positions by Mr. Champreux gives the date of perihelion as December 25·17 Greenwich.

REMARKABLE VARIATION IN THE SPECTRUM OF ζ BOOTIS.—In No. 4067 of the *Astronomische Nachrichten* Drs. H. Ludendorff and G. Eberhard direct attention to some remarkable variations which took place very suddenly in the spectrum of the double star ζ Boötis.

A spectrogram taken on June 3, 1905, showed a number of bright emission bands undoubtedly similar to those seen in the spectra of new stars, but another spectrum taken on June 5 showed no trace of these.

On looking over previous spectra obtained at the Potsdam Observatory on June 3, 4, and 26, 1902, respectively, only the hydrogen series lines, the calcium line λ 3934, the magnesium line λ 4481, and possible traces of other absorption lines could be detected. No bright bands were present.

The star is a well known double, classed as a "Sirian" star by Sir Norman Lockyer, as belonging to class I.*a*2 by Prof. Vogel, and as a class A star in the Draper Catalogue.

The question of the variability of the relative brightness of the two components has been much discussed, but was affirmed by W. Struve, Sir W. Herschel, and O. Struve.

A BRILLIANT FIREBALL.—In No. 368 of the *Observatory* Mr. Denning has brought together a large number of observations of a magnificent fireball which was seen in Scotland and the northern counties of England on December 30, 1905.

The meteor appeared at about 4h. 26m., swelled out into a disc, which one observer states was about half the size of the moon, and disappeared when about 10°–15° above the horizon. The trail left by the meteor lasted for about twelve or thirteen minutes according to most observers, and during that time was contorted into a variety of peculiar forms.

From the insufficient data yet to hand, Mr. Denning supposes that this object was a very late ϵ Arietid, having its radiant point at about 40°+23°, and on this supposition the height of the meteor works out at sixty-seven miles over Thornhill, in Dumfries, to twenty-seven miles over a point some six miles south of Arran. The earth-point would be about ten miles N.E. of Rathlin.

Thus the length of the path would be seventy-two miles and the velocity about fifteen miles per second.

In the same journal (Nos. 367 and 368) there is published an interesting discussion of the 1905 Bielid meteors by Prof. A. S. Herschel.

OBSERVATIONS OF PHŒBE DURING 1905.—A number of photographic measures of Phœbe, made during the period May 9 to December 14, 1905, are given in Circular 109 of the Harvard College Observatory. The usual exposure given to each photograph was two hours, and only very faint images of the satellite were obtained; thus they were very difficult to measure exactly, and the resulting residuals are somewhat large.

It is seen from the measures that Phœbe attained its maximum distance from Saturn, viz. 36′·4, on September 5. The average differences between the observed distances and declinations and those computed from the ephemeris published in vol. liii. of the Annals (p. 141) were about −0′·2 and −0′·6 respectively.

THE LEEDS ASTRONOMICAL SOCIETY.—The Journal and Transactions of the Leeds Astronomical Society (No. 12) has just been received, and contains a number of interesting papers which were read before the society during 1904.

In addition to these there is a *résumé* of the society's work during the year, as shown by a number of communications to various journals.

Non-members may obtain the journal for 1*s.* 6*d.* from Messrs. Jackson and Son, Leeds.

NEW MAGAZINES OF BIOLOGICAL CHEMISTRY.

JOURNALS dealing with the chemical aspects of physiological and pathological research have long been current in Germany; but up to the present time English-speaking workers have had to rely on periodicals dealing with all branches of physiology and pathology for the publication of their results. This is by no means disadvantageous to the readers of such journals, for overspecialisation has its drawbacks. But with the ever increasing activity in the biochemical field of research, the need has for long been felt of a special journal, and we have to chronicle the advent of one—the *Bio-chemical Journal*—which supplies the need, under the editorship of Prof. Benjamin Moore and Dr. Whitley, of the Liverpool University. In America also a similar want has been met by the issue of the first numbers of what is there called the *Journal of Biological Chemistry*, which is edited by Prof. Christian Herter, of New York, and Prof. J. J. Abel, of Baltimore.

The prefix *bio* and the adjective *biological* indicate a wider outlook than was implied by the older expression physiological chemistry, for there are chemical matters which have bearings, not only on physiology, but on botany, zoology, and pathology; and, indeed, this broad scope is already recognisable in the early issues of both the journals mentioned. It will be sufficient to take the English journal as an example. In the first number, just to hand, there is a paper by Mr. Joseph Barcroft dealing with the oxygen tension in the salivary glands and saliva, and throwing new light on the question of internal respiration in general. The professor of botany at Liverpool, Mr. Harvey Gibson, contributes an article on the physiological properties of West Indian boxwood, so much used now by the shuttle-makers of the north. The cardiac symptoms noticed in many of these workers are shown to be due to an alkaloid in the wood, which is dissolved out by the perspiration on the hands of the workpeople, and slowly absorbed into the system. Drs. Edie and Whitley describe methods for estimating the daily gain or loss of fixed alkali from the body, and the organic acids in the urine; the application of their results in the case of diabetes is pointed out. It was previously known that in acid poisoning the body protects itself by an increased formation of ammonia from urea; it is now shown that there is a similar protective mechanism at work against excess of alkali in the production of an increased amount of organic acids from carbohydrates. The last paper, by Drs. Moore, Edie, and Abram, more directly illustrates the application of chemical studies to the elucidation of disease. They find that the administration of a neutralised acid extract of the duodenal mucous membrane counteracts diabetes in the few cases examined up to the present. The explanation advanced of the benefit is that the extract stimulates the pancreas to form that internal secretion which regulates carbohydrate metabolism, but which is apparently in abeyance in the diabetic state.

Enough has been said to show the interesting and important kind of material at hand, and we wish our two new contemporaries every success in the future.

FORESTRY IN THE UNITED STATES.

THE United States Geological Survey has already issued in the form of reports various papers dealing with the conditions of the localities in the more important forest reserves. Professional Paper No. 29 of the forestry series of the department deals with the forest conditions in the Absaroka division of the Yellowstone Forest Reserve, Montana, and the Livingstone and Big Timber Quadrangles. This report first treats of the location, extent, and topography of the Yellowstone Reserve. The forest itself is almost wholly coniferous, consisting of pines, spruce, silver and Douglas firs. A most interesting account is given concerning the distribution of these species, especially in regard to altitude and aspect. As regards the ages of the trees the greatest diversity prevails. Age classes occur, varying from 15 to 20 years, 75 to 100 years; also stands from 200 to 300 years old are represented, this condition of things having been brought about by fire, the different age-classes corresponding to burns of different periods. The character and volume of merchantable timber are next carefully gone into. These naturally vary according to the species of tree, as well as the altitude and aspect in which it is growing, and the report brings out very interesting facts in this connection.

FIG. 1.—Cultivated Valley in the Woodland Area of the Lincoln Forest Reserve, New Mexico.

Like other forest reserves, the present one is divided into a number of smaller divisions called townships, which are carefully described in detail. Two useful land classification maps are appended.

A report of the forest conditions in the Little Belt Mountains Forest Reserve, Montana, and the Little Belt Mountains Quadrangle, forms Paper No. 30 of the same series. Here again the principal species are conifers; but the chief value of the forest lies in its effect on the conservation and regulation of the rainfall, hence it is more in the nature of a protection forest than one preserved for its timber production.

The forest conditions of the Lincoln Forest Reserve, New Mexico, are described in Paper No. 33. This reserve was created by proclamation of the President in 1902. The description of the included area is again given by townships. The area is more or less mountainous, and, as a natural consequence, the woodland growths are found to be divided into zones determined by altitude. A very interesting graphical representation of the various zones and species occurring in them is included. Short descriptions of the different species of trees are given, among which the yellow pine (*Pinus ponderosa*) is the chief timber tree. The conservation of trees in the reserve is of enormous importance in connection with the irrigation of cultivated lands in its neighbourhood, or vast areas that could be used for agricultural purposes if a regular supply of water were secured. Artificial tanks are at present employed for the storage of intermittent surface flows of water to be used for domestic purposes and irrigation.

Paper No. 39 consists of a report of the forest conditions of the Gila River Forest Reserve, New Mexico. This reserve was established by President McKinley in 1889. The reserve includes several prominent mountain ranges, and on the whole the area is well watered, the streams from the mountains carrying a considerable flow to a long distance beyond the forest regions. The reserve is traversed by fairly good roads and trails which follow the valleys. Agriculture is extensively carried on along San Francisco River, but not to such an extent along Gila River. The settlers formerly found a very ready market for their produce in the mining camps at Cooney and Mogollon, but several of these camps have been deserted within the last year or two, and the market has become considerably restricted. Grazing is an important industry in this region, but will require careful attention and supervision to prevent the inevitable result of over-stocking, as this not only leads to a total destruction of the grass roots, but also gives rise to drought at one period and disastrous flooding at another. The yellow pine is found to grow very well in this region, and will probably form the principal species in re-stocking the land when the older timber is removed.

FIG. 2.—Artificial "Tank" for Water Supply. Lincoln Forest Reserve, New Mexico.

FORTHCOMING BOOKS OF SCIENCE.

MESSRS. BAILLIERE, TINDALL AND COX'S list includes :—"Applied Bacteriology," by Prof. R. T. Hewlett and C. G. Moor, illustrated; "Laboratory Manual of Physiology," by Dr. F. C. Busch; "Trypanosomes and Trypanosomiasis," by Laveran and Mesnil, translated and edited by Dr. D. Nabarro; "Practical Agricultural Chemistry," by F. Robertson; "Röntgen Rays in General Practice," by R. H. Cooper; and a new edition of "Philosophy of Voice," by C. Lunn.

Messrs. A. and C. Black promise :—"A Treatise on Zoology," edited by Prof. E. Ray Lankester, F.R.S., part v., "Mollusca," by Dr. P. Pelseneer, illustrated.

Messrs. Gebrüder Borntraeger (Berlin) give notice of :—"Hygienisches Centralblatt," edited by Dr. P. Sommerfeld; "Zeitschrift für Gletscherkunde," edited by Prof. E. Brückner; "Tabulae botanicae," edited by Drs. E. Baur and Jahn; "Kryptogamenflora der Mark Brandenburg," Band ii., *Laubmoose*; "Forstbotanisches Merkbuch," iv., *Schleswig-Holstein*; "Allgemeine Botanik," by Prof. Warming; and "Geschichte Roms," by Prof. Drumann, Band iii.

The Cambridge University Press list includes :—"Cambridge Tracts in Mathematics and Mathematical Physics," No. 3, "Quadratic Forms and their Classification by Means of Invariant Factors," by Prof. T. J'A. Bromwich; "Trigonometry for Beginners," by J. W. Mercer. The following are in preparation :—"The Definite Integral, its Meaning and Fundamental Properties," by Dr. E. W. Hobson, F.R.S.; "Singular Points and Asymptotes of Plane Curves," by Prof. C. A. Scott; "The Axioms of Geometry," by Dr. A. N. Whitehead, F.R.S.; and "The Eikonal and its Application to Optical Instruments," by E. T. Whittaker, F.R.S.

Messrs. J. and A. Churchill give notice of :—"A Short Practice of Medicine," by Dr. R. A. Fleming; "Preservatives in Food and Food Examination," by Dr. J. C. Thresh; "Essentials of Surface Anatomy," by C. R. Whittaker; "A Manual of Midwifery," by Dr. T. W. Eden; "Clinical Applied Anatomy; or, the Anatomy of Medicine and Surgery," by C. R. Box and W. M. Eccles; "A Manual of Pathology, General and Special," by Prof. R. T. Hewlett; "A Manual of Prescribing," by Prof. C. R. Marshall; "Spinal Curvature," by H. R. H. Bigg; "Pharmaceutical Latin Grammar; or Prescriptions, how to Write and Read Them," by R. R. Bennett; and new editions of "A System of Dental Surgery," by C. S. Tomes and W. S. Nowell; and "Minor Surgery and Bandaging," by B. Pollard.

Messrs. A. Constable and Co., Ltd., will publish :—"Radio-active Transformations," by Prof. E. Rutherford, F.R.S., illustrated; "The Integrative Action of the Nervous System," by Prof. C. S. Sherrington, F.R.S., illustrated; and "Physiology of the Nervous System," by J. P. Morat translated and edited by Dr. H. W. Syers, illustrated.

Messrs. J. M. Dent and Co. direct attention to :—"English Men of Science," edited by Prof. J. R. Green, F.R.S.—"Herbert Spencer," by Prof. J. A. Thomson; "Priestley," by Dr. T. E. Thorpe, C.B., F.R.S.; "George Bentham," by B. D. Jackson; "Huxley," by Prof. J. R. A. Davis; "Sir Wm. Flower," by R. Lydekker, F.R.S. Of Dent's Mathematical and Scientific Series, the following are in preparation :—"Geometrical Conics," by Profs. G. H. Bryan, F.R.S., and R. H. Pinkerton; "Analytical Conics," by Prof. C. A. Scott; "Mechanics," by C. S. Jackson and R. M. Milne; "Trigonometry," by C. Hawkins; "Algebra," by Prof. H. W. Ll. Tanner, F.R.S., and W. J. Greenstreet; "Practical Mathematics," by J. E. Boyt; "Light," by F. E. Rees; "A French Scientific Reader," compiled by W. J. Greenstreet; "A German Scientific Reader," compiled by C. R. Dow; and "Mathematical Tables," by Prof. G. H. Bryan, F.R.S.

Mr. Gustav Fischer (Jena) announces :—"Flora, oder Allgemeine Botanische Zeitung," Jahrgung 1906, edited by Prof. K. Goebel, Heft i., illustrated; "Klinisches Jahrbuch," fünfzehnter Band, zweites Heft, illustrated; "Physiologie des Menschen," by Prof. L. Luciani, German translation, Band ii., illustrated; "Das Rettungs- und Krankenbeförderungswesen im deutschen Reiche," by Prof. G. Meyer, Bildet zugleich den dritten Ergänzungsband zum klinischen Jahrbuch, illustrated; "Résultats scientifiques du Congrès international de Botanique, Wien, 1905," illustrated; "Die Wirbeltiere Europas mit Berücksichtigung der Faunen von Vorderasien und Nordafrika," by Prof. O. Schmiedeknecht; "Vegetationsbilder," edited by Profs. G. Karsten and H. Schenck, dritte Reihe, Heft vi.: Emerich Zederbauer, Vegetationsbilder aus Kleinasien, illustrated; "Verhandlungen der deutschen pathologischen Gesellschaft," edited by G. Schmorl, neunte Tagung, gehalten in Meran vom 25 bis 29 September, 1905, illustrated; "Gesammelte Abhandlungen," Band iv., Sozialpolitische Schriften, by Prof. E. Abbe; and new editions of "Lehrbuch der Entwicklungsgeschichte des Menschen und der Wirbeltiere," by Prof. O. Hertwig, illustrated; "Tabellen zur Gesteinskunde für Geologen, Mineralogen, Bergleute, Chemiker, Landwirte und Techniker," by Prof. G. Linck, illustrated; "Einführung in das Studium der Malariakrankheiten," by Dr. R. Ruge, illustrated; "Anatomische, physiologische und physikalische Daten und Tabellen zum Gebrauche für Mediziner," by Prof. H. Vierordt; and "Lehrbuch der allgemeinen Pathologie und der pathologischen Anatomie," by Prof. E. Ziegler, Band ii., Lehrbuch der speziellen pathologischen Anatomie, edited by Drs. E. Gierke and K. Ziegler, illustrated.

Messrs. Gauthier-Villars (Paris) promise :—"Guide du Météorologiste amateur," by Loisel; "Leçons sur le Séries trigonometriques," by Lebesque; "La Mécanique des Phénoménes fondée sur les Analogies," by Petrowitch; and "Les Conserves alimentaires," by Rocques.

Messrs. Charles Griffin and Co., Ltd., announce :—"The Theory of the Steam Turbine, a Treatise on the History, Development, and Principles of Construction of the Steam Turbine," by A. Jude, illustrated; "Present-day Shipbuilding: abridged from 'Steel Ships,' Revised and Specially Arranged to Meet the Requirements of Shipyard Students, Ships' Officers, and Engineers for their Respective Examinations," by T. Walton, illustrated; "Motor-car Mechanism and Management," by W. P. Adams, in three parts, illustrated, part ii., the Electrical Car, and part iii., the Steam Car; "General Foundry Practice: a Practical Handbook for Iron, Steel and Brass Founders, Metallurgists, and Students of Metallurgy," by A. C. McWilliam and P. Longmuir, illustrated; "The Elements of Chemical Engineering," by Dr. J. Grossmann, illustrated; "Locomotive Compounding and Superheating," by J. F. Gairns, illustrated; "Peat: its Use and Manufacture," by P. R. Björling and F. T. Gissing, illustrated; "The Clayworker's Handbook, an Epitome of the Materials and Methods Employed in Brickmaking and Pottery," by the author of "The Chemistry of Clayworking," illustrated; "Paper Technology, an Elementary Manual on the Manufacture, Physical Qualities, Chemical Constituents, and Testing of Paper and Paper-making Fibres, with Selected Tables for the Use of Publishers, Stationers, and Others," by R. W. Sindall, illustrated; "Lessons on Sanitation," by J. W. Harrison, illustrated; "Toxines and Antitoxines," by Dr. C. Oppenheimer, translated from the German by C. A. Mitchell, with notes and additions by the author, since the publication of the German edition; "The Treatment of the Diseases of the Digestive System," by Prof. R. Saundby; and new editions of "Chemistry for Engineers and Manufacturers," by B. Blount and A. G. Bloxam, vol. i., the Chemistry of Engineering, Building, and Metallurgy; "Petroleum and its Products, a Practical Treatise," by Sir B. Redwood, illustrated; and "Aids in Practical Geology: with a Section on Palæontology," by Prof. G. A. J. Cole, illustrated.

Messrs. Hodder and Stoughton give notice of :—"A History of Egypt from the Earliest Times to the Persian Conquest," by Prof. J. E. Breasted, illustrated; "Every Man's Book of Garden Difficulties," by W. F. Rowles, illustrated; "Every Man's Book of Garden Flowers, with Short Directions for their Culture," by J. Halsham, illustrated; and "A Nature Reader for Senior Students, being an Anthology of the Poetry of Nature," edited by the Hon. Sir John Cockburn, K.C.M.G., and E. E. Speight.

Messrs. Hutchinson and Co. announce :—"Liberia, the Negro Republic in West Africa," by Sir Harry Johnston, G.C.M.G., K.C.B., &c., illustrated; Darwin's "Origin of Species," edited by J. W. Mathews; and Waterton's

"Wanderings in South America," with notes, &c., by W. A. Harding.

In Mr. John Lane's list are:—"Bombay Ducks: an Account of Some of the Everyday Birds and Beasts found in a Naturalist's El Dorado," by D. Dewar, illustrated; "The Wild Flowers of Selborne and Other Papers," by the Rev. Canon Vaughan, illustrated. New volumes in the "Practitioners' Library," edited by H. Roberts: "Forms of Paralysis," by Dr. J. S. Collier; "X-Rays in General Practice," by Captain A. E. Walter. New volumes in the Country Handbooks, edited by H. Roberts: "The Stable Handbook," by T. F. Dale, illustrated; "The Country Cottage," by G. L. Morris and E. Wood, illustrated. New volumes in the Handbooks of Practical Gardening: "The Book of Rarer Vegetables," by G. Wythes and H. Roberts; "The Book of the Winter Garden," by D. S. Fish; "The Book of Market Gardening," by R. L. Castle, illustrated; and a new edition of "Rifle and Romance in the Indian Jungle: being the Record of Thirteen Years of Indian Jungle Life," by Captain A. I. R. Glasfurd, illustrated.

Mr. T. Werner Laurie will publish:—"Fishing for Pleasure and Catching It," by E. Marston, with two chapters on Salmon and Trout Fishing in North Wales by R. B. Marston, illustrated; and "Modern Medicine for the Home," by E. Walker.

Among Messrs. Crosby Lockwood and Son's forthcoming books we notice:—New editions of "The Art of Leather Manufacture," by A. Watt; "Colliery Working and Management," by H. F. Bulman and R. A. S. Redmayne, illustrated; "A Handybook for Brewers," by H. E. Wright; and "Sheet Metal Worker's Instructor," by R. H. Warn and J. G. Horner, illustrated.

Messrs. Longmans and Co.'s list includes:—"Mammals of Great Britain and Ireland," by J. G. Millais, vol. iii., completing the Rodentia with the Hares and the Rabbit; it will also contain the Cervidæ (the Deer family), the Bovidæ (the Oxen), and the Cetaceæ (Whales), illustrated; "Health of Our Children in the Colonies, a Book for Mothers," by Dr. L. A. Robinson; "Plants and their Ways in South Africa," by B. Stoneman; "Design of Lathes for High Speed and Heavy Cutting," by J. T. Nicolson and D. Smith; "Practical Manual of Tides and Waves," by W. H. Wheeler, illustrated; "Scientific Principles of Wireless Telegraphy," by Prof. J. A. Fleming, F.R.S.; "Modern Steam Road Wagons," by W. Norris, illustrated; "Synthetica, being Meditations Epistemological and Ontological, comprising the Edinburgh Gifford Lectures of 1905," by Dr. S. S. Laurie, two vols.; "Plant Response," by Prof. J. C. Bose, C.I.E.; "Mathematical Papers of J. Willard Gibbs," two vols.; "Manual of Diseases of the Nose and its Accessory Cavities," by Dr. H. L. Lack; and "Philosophy of Religion," by Prof. G. T. Ladd, two vols.

Messrs. Sampson Low, Marston and Co., Ltd., will issue:—"Cotton Manufacture," by E. A. Posset, part ii., treating of combing, drawing, roller covering and fly frames, with an illustrated description of all the modern processes and machinery used, also all the calculations required.

Messrs. Macmillan and Co., Ltd., announce:—"Mediæval Rhodesia," by D. Randall-MacIver, illustrated; "The Philosophy of Religion," by Prof. H. Höffding, translated by Miss B. E. Meyer; "Electrical Engineering in Theory and Practice," by G. D. Aspinall Parr, illustrated; "Physical Optics," by Prof. R. W. Wood, illustrated; "A Manual of Geometry," by W. D. Eggar; "Lessons in Science, a Preliminary Course of Physics and Chemistry," by Prof. R. A. Gregory and A. T. Simmons; and a new edition of "Appendicitis: its Pathology and Surgery," by C. B. Lockwood.

Messrs. Methuen and Co. promise:—"Electrical Industry, Lighting, Traction, and Power," "Shipbuilding Industry, its History, Science, Practice, and Finance," "Money Market," "Business Side of Agriculture," "Brewing Industry," "Automobile Industry," "Mining and Mining Investments," "Civil Engineering," "Coal Industry," "Iron Trade," and "Cotton Industry and Trade."

Mr. John Murray announces:—"Heredity," by Prof. J. A. Thomson; "Researches in Sinai," by Prof. W. Flinders Petrie, F.R.S., illustrated; "Noteworthy Families (Science), an Index to Kinships in Near Degrees between Persons whose Achievements are Honourable, and have been Publicly Recorded," by Dr. F. Galton, F.R.S., and E. Schuster; "Our Waterways, a History of Inland Navigation considered as a Branch of Water Conservancy," by U. A. Forbes and W. H. R. Ashford; "Life of Isabella Bird (Mrs. Bishop)," by Miss A. M. Stoddart, illustrated; "The Dead Heart of Australia, a Journey around Lake Eyre in the Summer of 1901–1902, with an Account of the Lake Eyre Basin and the Flowing Well of Central Australia," by Prof. J. W. Gregory, F.R.S., illustrated; "Human Blood, an Introduction to the Normal and Pathological Morphology of Human Blood," eight lectures delivered in the Pathological Laboratory of the University of London, by Dr. G. A. Buckmaster, illustrated; "The Transition in Agriculture," by E. A. Pratt; "Recent Development in Biological Science," by W. B. Hardy, F.R.S.; "Artillery and Explosives, Essays and Lectures Written and Delivered at Various Times," by Sir A. Noble, K.C.B., F.R.S., illustrated; and "Chemistry of the Albumens," by Dr. O. B. Schryver.

The list of the Oxford University Press contains:—"Elementary Chemistry, Progressive Lesson in Experiment and Theory," by F. R. L. Wilson and G. W. Hedley, part ii.; Knuth's "Flower Pollination," authorised English translation by J. R. A. Davis, vol. i.; Solereder's "Anatomical Characters of the Dicotyledonous Orders," authorised English translation by L. A. Boodle and F. E. Fritsch, revised by H. D. Scott; "A Catalogue of the Herbarium of Dillenius," by G. C. Druce, with the assistance of Prof. S. H. Vines, F.R.S.; "The Face of the Earth" ("Das Antlitz der Erde"), by Prof. E. Suess, translated by Dr. H. B. C. Sollas under the direction of Prof. W. J. Sollas, F.R.S., vol. ii., illustrated; "The Oxford Geographies," vol. ii., "The Preliminary Geography," by Dr. A. J. Herbertson, illustrated; "The Dawn of Modern Geography," by C. R. Beazley, vol. iii.; "Lectures on the Method of Science," edited by Dr. T. B. Strong; and a new edition of "Human Anatomy for Art Students," by Prof. A. Thomson, illustrated.

Messrs. G. Philip and Son, Ltd., have in the press:—"A Rhythmic Approach to Mathematics," by E. L. Somervell.

Sir Isaac Pitman and Sons, Ltd., announce:—"Mechanical Traction on Highways in the United Kingdom," by Dr. C. A. M. Barlow; and a new edition of "Home Gymnastics for Old and Young," by Dr. T. J. Hartelius, translated and adapted from the Swedish by C. Löfving, illustrated.

Messrs. G. P. Putnam's Sons promise:—"Jordan Valley and Petra," by Prof. W. Libbey and Dr. F. E. Hoskins, two vols., illustrated; and "Tibet and Turkestan," by O. T. Crosby, illustrated.

The Religious Tract Society announces:—"By-paths in Nature," by F. Stevens, illustrated; and "Every Boy's Book of British Natural History," by P. Westell.

The Sanitary Publishing Co., Ltd., announce:—"Smoky Fogs, How to Prevent," by A. J. Martin; "Drainage, Cast Iron House Drainage, with Especial Reference to the Drainage of Town Houses," by G. J. G. Jensen; and new editions of "Drainage, By-laws as to House Drainage and Sanitary Fittings made by the London County Council," annotated by G. J. Jensen, illustrated; and "Drainage, Modern Drainage Inspection and Sanitary Surveys," by G. J. G. Jensen, illustrated.

The Society for Promoting Christian Knowledge will publish:—"The Frozen South"; a volume on the Spectroscope, by Mr. H. F. Newall; and "The Properties of Liquids," by Prof. C. V. Boys, F.R.S.

Messrs. Swan Sonnenschein and Co., Ltd., promise:—"Physiological Psychology," by Prof. W. Wundt, translated by Prof. E. B. Titchener, in three vols., vol. ii., illustrated; "The History of Philosophy," by Dr. J. E. Erdmann, translated abridgment by W. S. Hough; "Thoughts and Things: a Genetic Study of Logical Process," by Prof. M. Baldwin, vol. i., "Theory of Knowledge, Functional Logic," vol. ii., "Theory of Reality, Real Logic"; "Man: or Problems Ancient and Modern relating to Man, with Guesses at Solutions," by Rev. W. T. Nicholson; "The Student's Text-book of

Zoology," by A. Sedgwick, F.R.S., vol. iii., completing the work, illustrated; "Insect Pests of the Farm and Garden," by F. M. Duncan, illustrated; and "School Gardening for Little Children," by L. R. Latter, with an introduction by Prof. Geddes.

The University Tutorial Press, Ltd., announce:—"Geometry, Theoretical and Practical," by W. P. Workman and A. G. Cracknell, part ii., part iii.; "Arithmetic for the Preliminary Certificate Examination," by H. R. Chope; "Model Answers to Arithmetic Questions for the Preliminary Certificate Examination"; "Algebra, Preliminary Certificate Edition, With Section on Graphs," by R. Deakin; "Geometry, Theoretical and Practical, Preliminary Certificate Edition (for Course A)," by W. P. Workman and A. G. Cracknell; "Euclid, Books i.–iii., Preliminary Certificate Edition, with Mensuration and Practical Problems arranged in Accordance with Euclid's Order of Proof," by R. Deakin; "Key to Matriculation Algebra"; "Logarithms and How to Use Them"; "Chemistry, First Stage, Theoretical Organic," by R. A. Lyster; "Chemistry, the Junior," by R. H. Adie; "Experimental Science, the Junior," by W. M. Hooton; "Hygiene, Certificate," by R. A. Lyster; "Technical Electricity," by Prof. H. T. Davidge and R. W. Hutchinson; "Physiology, First Stage," by Dr. G. M. Meachen; "Elementary Science of Common Life (Chemistry), Subject xxvi. of the Board of Education Science Examinations," by W. T. Boone; "Properties of Matter," by C. J. L. Wagstaff; "Elementary Science for the Preliminary Certificate Examination (General Section)," edited by Drs. R. W. Stewart and W. Briggs; "Elementary Science for the Preliminary Certificate Examination (Section A, Chemistry)," by H. W. Bausor; "Elementary Science for the Preliminary Certificate Examination (Section B, Physics)," by J. Satterly; "Intermediate Hydrostatics"; "Principles and Methods of Education," by Dr. S. S. Fletcher and J. Welton; and new editions of "First Stage Inorganic Chemistry (Theoretical)," by Dr. G. H. Bailey; "Synopsis of Matriculation Chemistry"; "New Matriculation Physics: Heat, Light, and Sound," by Dr. R. W. Stewart; "Light, Text-book of," by Dr. R. W. Stewart; and "Graphs, Graphical Representation of Algebraic Functions," by C. H. French and G. Osborn.

Mr. T. Fisher Unwin promises:—"Haeckel: his Life and Work," by W. Bölsche, translated by J. McCabe, illustrated; and "The Birds of Middlesex," by J. E. Harting, illustrated.

The following are Messrs. Whittaker and Co.'s announcements:—"A Pocket Book of Aëronautics," by H. W. L. Moedebeck, translated from the German by Dr. W. M. Varley; "Electricity in Mines," by P. R. Allen; "Steam Turbine Engineering," by T. Stevens and H. M. Hobart; "Electric Lamps and Electric Lighting," by L. Gaster; "Armature Construction, a Handbook for Electrical Designers," by H. M. Hobart; "Single-phase Commutator Motors," by F. Punga; "A Treatise on Coal Mining," by G. L. Kerr and D. Burns; "Polyphase Electric Currents," by A. Still; and "A Text-book of Botany," part i., "The Anatomy of Flowering Plants," by L. M. Yates.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The board of the faculty of natural science has approved the supplication of Mr. Walter Garstang, Lincoln College, for the degree of doctor of science.

Prof. W. J. Sollas and Dr. T. G. Bonney have been appointed examiners in the honour school of geology.

The grant of 250*l*. a year to the pathological laboratory from the University Chest has been renewed for five years, and additional grants of 100*l*. a year to the Pitt-Rivers Museum and to the Hope department of zoology, and 50*l*. a year to the departments of mineralogy and geology have been authorised by Convocation.

The important collection of New Zealand birds formerly belonging to the late Mr. S. William Silver has been presented to the museum by his widow.

A fellowship examination in chemistry has been announced by Merton College to begin on Tuesday, September 25. Candidates must have passed at the examinations required by the University for the degree of B.A. The value of the fellowship is 200*l*. a year for seven years, and the holder may be re-elected if he is duly qualified. Candidates may submit any dissertations or evidence of research work not later than September 20.

At a meeting of the Junior Scientific Club held on March 7, Mr. Henry Balfour read a paper on "The Natural History of the Bagpipe," and Mr. J. A. Brown one on "Electrons."

CAMBRIDGE.—The late Mr. Frederick James Quick having left his residuary estate to the University, the income to be used in promoting the study and research in the sciences of vegetable and animal biology, the council of the Senate has published a scheme for the administration of the fund. This has been approved by the trustees, to whom the will entrusts very considerable powers of emendation and alteration. It is proposed to establish a Quick professorship of biology with a salary of 1000*l*. a year, and with a sum not exceeding 300*l*. a year for the maintenance of a laboratory. In the first instance the professor is to devote himself to the study of the protozoa, especially such as cause disease. He will not be required to give lectures in more than one university term, when he will be expected to set forth the result of the researches carried on in his laboratory. By the terms of the will the professor must seek re-election every third year. The administration of the fund will rest with a board of managers, the members of which will also act as electors to the professorship.

The first report of the Studies and Examinations Syndicate with regard to the abolition of compulsory Greek having been rejected by the Senate, the Syndicate has tried again, and has issued a second report, in which it suggests what is known as a "bifurcation of studies." It is proposed that both in the honours and in the ordinary course for degrees the examinations shall be grouped into two sections, the literary and the scientific, and that while those who pursue the literary side must take in the Previous Examination two classical languages, those on the scientific side will be required "to take two languages other than English, one of the two being Latin or Greek." When the proposals come to be discussed a certain amount of opposition may be expected from the historians and moral science teachers, whose students are afforded no relief. Whether the masters of the situation, the non-resident members of the Senate, will allow the proposals to be accepted is doubtful. It is a well known fact that when the first report of the Syndicate was voted upon, a decided majority of the resident members of the University voted for reform. If the residents are again beaten they must put their trust in the Royal Commission which, from various signs, seems not so very far off.

The late master of Corpus Christi College, Dr. E. H. Perowne, has left his valuable collection of amber from the Norfolk coast to the University, to be deposited in the Sedgwick Geological Museum or in the Fitzwilliam Museum.

It is proposed to grant a sum of 75*l*. out of the works fund to Mr. W. G. Fearnsides, of Sidney Sussex College, towards defraying the expense of a visit which he proposes to make to Sweden to study the Tremadoc and Arenig beds.

The following have been appointed examiners in the special examination in geography and the examination for the diploma in geography:—Mr. G. G. Chisholm, Mr. A. R. Hinks, Mr. H. Y. Oldham, and Prof. W. W. Watts.

The next combined examination for sixty-six entrance scholarships and various exhibitions at Pembroke, Gonville and Caius, King's, Jesus, Christ's, St. John's, and Emmanuel Colleges will be held on Tuesday, December 4, and following days. Mathematics, classics, and natural sciences will be the subjects of examination at all these colleges. Scholarships and exhibitions will also be offered for history, for modern languages, and for Hebrew.

WE learn from *Science* that Mrs. A. A. Anderson has given 20,000*l*. to Barnard College, Columbia University, toward the establishment of a course in science.

THE fifth annual students' soirée of the Sir John Cass Technical Institute will be held on Saturday, March 17. The guests will be received by Sir Owen Roberts, chairman of the governing body, and Lady Roberts, Mr. George Baker, J.P., vice-chairman of the governing body, and Mrs. Baker. Short lectures and demonstrations on scientific subjects will be given during the evening.

AT the last meeting of the council of the University of Birmingham several appointments to the staff were made. Mr. George S. West was appointed assistant lecturer and demonstrator in botany in succession to Dr. A. J. Ewart; Dr. Theodore Groom was appointed senior lecturer in geology and geography to succeed Prof. W. W. Watts, F.R.S., recently appointed to the chair of geology in the Royal College of Science, London; and Mr. Donald M. Levy was appointed demonstrator in metallurgy to succeed Mr. H. N. Schnurmann. Communications were received announcing the bequest by the late Mr. John Feeney of the sum of 20,000*l.*, a donation from Messrs. W. and T. Avery, Ltd., of 500*l.*, and valuable gifts from Messrs. Veritys, Ltd., Mr. J. C. Vaudrey, and Mr. Willoughby Ellis. An assistant lectureship and demonstratorship in civil engineering was established.

FOR the last few years Oberlin College has been engaged, says *Science*, in raising a fund of 100,000*l.* This is now almost complete. The fund was started by an anonymous donor of Boston, who promised 20,000*l.* At the time of the trustees' meeting in November last the fund had reached 67,000*l.* Since then numerous gifts have been made, including 1000*l.* for library endowment, 400*l.* for additions to the women's gymnasium, 2000*l.* toward a men's building, 6600*l.* from the estate of Dr. C. N. Lyman, of Wadsworth, O., which will be devoted to library endowment, 15,000*l.* to be used as endowment for the Slavic department of the seminary, 2000*l.* for library endowment, and 1000*l.* for the art building. In the total of 97,000*l.* now raised is counted 25,000*l.* promised by Mr. Carnegie for a library, on condition that 20,000*l.* be raised for library endowment. To complete the fund, therefore, it will be necessary for the college to raise about 10,000*l.* more. It is expected that this will be done before commencement.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, March 1.—Mr. A. G. Vernon Harcourt, F.R.S., past president, in the chair.—Studies of dynamic isomerism, part iv., stereoisomeric halogen derivatives of camphor: T. M. **Lowry.** Measurements were given of the solubility in alcohol of α-chloro- and α-bromocamphors, $\alpha\beta$- and $\alpha\pi$-dibromocamphors, and $\alpha\beta$- and $\alpha\pi$-chlorobromocamphors, both alone and in presence of a small proportion of sodium ethoxide. The increase of solubility on addition of the alkali is ascribed to the formation in the solution of a small proportion of the stereoisomeric α'-compound.—The coagulating action of colloids, part i.: W. P. **Dreaper** and A. **Wilson.** The results obtained by the authors throw some light on dyeing and tanning processes. The influence of gallic acid in the manufacture of leather seems to be of a more direct nature than was previously supposed.—Studies on optically active carbimides, iii., the resolution of α-phenyl-α'-4-hydroxyphenylethane by means of *l*-menthylcarbimide: R. H. **Pickard** and W. O. **Littlebury.** The *l*-menthylcarbamates formed by combination with *l*-menthylcarbimide can be separated by fractional crystallisation, and are then hydrolysed by alcoholic sodium hydroxide.—Experiments on the synthesis of the terpenes, part viii., synthesis of the optically active modifications of Δ^3-*p*-menthenol(8) and $\Delta^{3:8(9)}$-*p*-menthadiene: F. W. **Kay** and W. H. **Perkin,** jun. Δ'-Tetrahydro-*p*-toluic acid, *l*-Δ^3-*p*-menthenol(8), $\Delta^{3:8(9)}$-*p*-menthadiene, and *d*-$\Delta^{3:8(9)}$-*p*-menthadiene have all been synthesised. By fractional crystallisation of the brucine and strychnine salts of the first-named compound it was resolved into optical isomerides, and from these the two other compounds were prepared in an optically active condition.—Studies in the acridine series, iii., the methylation of chrysaniline: A. E. **Dunstan** and J. T. **Hewitt.** —Note on the application of the electrolytic method to the estimation of arsenic in wall-papers, fabrics, &c.: T. E. **Thorpe.**—Nitrogen halides from camphoryl-ψ-carbamide: M. O. **Forster** and H. **Grossmann.** The action of potassium hypobromite and hypochlorite on camphoryl-ψ-carbamide has been found to give rise to dihalogen derivatives which have all the properties of compounds containing halogen attached to nitrogen.—The relation of position isomerism to optical activity, vi., the rotation of the menthyl esters of the isomeric chloronitrobenzoic acids: J. B. **Cohen** and H. P. **Armes.** In the present investigation the combined effect of the halogen and nitro-group on the activity of the menthyl group has been examined.

Mathematical Society, March 8.—Prof. W. Burnside, vice-president, and subsequently Sir W. D. Niven, vice-president, in the chair.—Sommerfeld's diffraction problem and reflection by a parabolic mirror: Prof. H. **Lamb.** Sommerfeld's problem is that of the diffraction of plane waves by a plane screen bounded by a straight edge. It is shown that Sommerfeld's solution may be arrived at in a simple way by combining certain simple particular solutions of the general equation of wave motion when expressed in terms of the coordinates that define two systems of confocal parabolic cylinders, the edge of the screen being the line of foci of the cylinders. Slightly modified forms of these solutions lead to a complete solution of the problem of reflection by a convex mirror in the form of a parabolic cylinder. It appears that in this application of the wave theory the reflected waves, which the ordinary processes of geometrical optics represent as diverging from a line of sources coinciding with the line of foci of the cylinder, really diverge from a plane of sources, terminated in an edge at this line, and extending thence with continually diminishing strength to an infinite distance on the concave side of the mirror. The problems of reflection by concave parabolic and paraboloidal mirrors are also discussed.—Function-sum theorems connected with the series $\sum\limits_1^\infty x^n/n^2$: Prof. L. J. **Rogers.** The sums of the values of the function defined by the integral $\int_0 -(1-x)^{-1}\log x dx$ for various sets of values of the argument are shown to have definite constant values.—Investigations on series of zonal harmonics: Prof. T. J. I'A. **Bromwich.** The paper relates to the behaviour of series of the type $\Sigma a_n r^n P_n(\cos\theta)$ in the neighbourhood of points on the boundary of the region of convergence.—The functions $g\beta(x, \theta)$ and $f\beta(x, \theta)$ Rev. E. W. **Barnes.** The paper deals with the asymptotic expansions of special types of integral functions.—The relations between the *p*-line determinants formable from a *p* by *q* array: Prof. E. J. **Nanson.**—An informal communication On the divisors of numbers of certain forms was made by Lieut.-Colonel A. **Cunningham.** The special forms are $q2^q+1$ and $(a^{4x}+1)^3+1$.—Dr. F. S. **Macaulay** made an informal communication On the equilibrium of forces of given magnitudes the lines of action of which pass through given points.

PARIS.

Academy of Sciences, March 5.—M. H. Poincaré in the chair.—The suboxides of carbon: M. **Berthelot.**—Some arithmetical consequences of the theory of Abelian functions: G. **Humbert.**—The propagation of a movement round a centre in an elastic, homogeneous, and isotropic medium: study of the wave produced without change of density: J. **Boussinesq.**—The bean containing hydrocyanic acid, *Phaseolus lunatus*: L. **Guignard.** Frequent cases of poisoning of animals by this bean have occurred, due to the hydrocyanic acid it contains. This acid arises from a glucoside, phaseolunatine, which is present in the bean. Determinations of the amounts of hydrocyanic acid obtainable from beans from various sources gave figures varying between 0·006 per cent. and 0·102 per cent. A new method for detecting traces of hydrocyanic acid is given.—The synthesis of three dimethyl-cyclo-hexanols: Paul **Sabatier** and A. **Mailhe.** The method of Sabatier and Senderens has been applied to the addition of hydrogen to the three xylenols. Details of the preparation of these substances are given, together with their physical properties and those of their immediate derivatives.—The mag-

netic chart of the British Isles: B. **Baillaud** and E. **Mathias.**—Observations of the sun made at the Observatory of Lyons with the 16 cm. Brunner equatorial during the fourth quarter of 1905: J. **Guillaume.** Observations were possible on thirty-three days during the quarter. The results are given in three tables showing the number of spots, the distribution of the spots in latitude, and the distribution of the faculæ in latitude.—The deformation of quadrics: Luigi **Bianchi.**—The singularities of solutions to some partial differential equations of the elliptic type: Serge **Bernstein.**—The measurement of the loss of phase by reflection: A. **Perot.**—The phenomena of phosphorescence: A. **Debierne.**—Contribution to the study of selenious anhydride: Œchsner **de Coninck.**—The iodomercurates of calcium and strontium: A. **Duboin.** Crystallised compounds were isolated possessing the composition $CaI_2.HgI_2.8H_2O$ for the calcium salt, and $SrI_2.5HgI_2.8H_2O$ for the corresponding strontium salt.—The nature of the decomposition of an aqueous solution of copper sulphate by some alloys of aluminium: H. **Pecheux.** In a previous note these reactions have been studied from the qualitative side. The present paper is concerned with the quantitative aspect of the same reactions.—The estimation of cadmium: H. **Baubigny.**—The thermochemistry of the hydrazones and the osazones: Ph. **Landrieu.**—The condensation of benzidine-aniline, diphenyl-bidiazoaminobenzene, and diphenyl-disazoaminobenzene: Léo **Vignon.**—An antimony tartrate: J. **Bougault.** It is shown that the use of alcohol in the preparation of antimony tartrate leads to an impure product; similar objections do not apply to acetone.—The chemical study of the seeds known as Java peas: Émile **Kohn-Abrest.** Determinations of the amounts of hydrocyanic acid produced by various modes of treating the seeds.—The chemical characters of the wines arising from vines attacked by mildew: E. **Manceau.**—The evolution of the Eccrina of Glomeris: L. **Léger** and O. **Duboscq.**—A natural mollusc-bearing layer in the Macta, Algeria, and the effect of the nature of the flow of this river on the growth of the molluscs: J. **Bounhiol.**—The ferments of the placenta: MM. **Charrin** and **Goupil.**—The duration of persistence of the activity of the isolated heart: M. **Lambert.**—The influence of old age on the arterial pressure: A. **Moutier.**—A Miocene volcanic chain on the eastern border of the Limagne: Ph. **Glangeaud.**—The discovery of two Cretacean horizons in Morocco: W. **Kilian** and L. **Gentil.**—The grand cañon of Verdon, its age and formation: E. A. **Martel.**

DIARY OF SOCIETIES.

THURSDAY, MARCH 15.

ROYAL SOCIETY, at 4.30.—A Discussion of Atmospheric Electric Potential Results at Kew from Selected Days during the Seven Years 1898 to 1904: Dr. C. Chree, F.R.S.—On the Specific Heat of, Heat Flow from, and other Phenomena of the Working Fluid in the Cylinder of the Internal Combustion Engine: Dugald Clerk.

CHEMICAL SOCIETY, at 8.30.—The Interaction of well dried Mixtures of Hydrocarbons and Oxygen: W. A. Bone and G. W. Andrew.—The Explosive Combustion of Hydrocarbons: W. A. Bone and J. Drugman.—The Occurrence of Marsh Gas amongst the Decomposition Products of Certain Nitrogenous Bases as a Source of Error in the Determination of Nitrogen by the Absolute Method: P. Haas.—Studies on Comparative Cryoscopy. Part IV. The Hydrocarbons and their Halogen Derivatives in Phenol Solution: P. W. Robertson.—The Displacement of Acid Radicles. I. Displacement of the Chloride and Nitrate Radicles: A. F. Joseph.

ROYAL INSTITUTION, at 5.—The Physiology of Plants: Francis Darwin, For. Sec. R.S.

LINNEAN SOCIETY, at 8.—Discussion on the Origin of Gymnosperms: Opened by Prof. F. W. Oliver, F.R.S.

SOCIETY OF ARTS, at 4.30.—The Languages of India and the Linguistic Survey: Dr. George A. Grierson.

INSTITUTION OF MINING AND METALLURGY, at 8.—A Record of an Investigation of Earth Temperatures on the Witwatersrand Gold Fields, and their Relation to Deep Level Mining in the Locality: H. F. Marriott.—Note on the Ammonia-Copper-Cyanide Process: E. Le Gay Brereton.—The Cyanide Treatment of Cupriferous Tailings by the Sulphuric Acid Process: W. S. Brown.

FRIDAY, MARCH 16.

ROYAL INSTITUTION, at 9.—How to Improve Telephony: W. Duddell.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—*Continued Discussion:* Large Locomotive Boilers. G. J. Churchward.—*Probable Paper:* Petroleum Fuel in Locomotives on the Tehuantepec National Railroad of Mexico: L. Greaven.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—Evolution in Relation to Disease: Dr. J. T. C. Nash.

SATURDAY, MARCH 17.

ROYAL INSTITUTION, at 3.—The Corpuscular Theory of Matter: Prof J. J. Thomson, F.R.S.

MONDAY, MARCH 19.

SOCIETY OF ARTS, at 8.—Fire, Fire Risks, and Fire Extinction: Prof Vivian B. Lewes.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—The Economic Geography of Australia: Prof. J. W. Gregory, F.R.S.

VICTORIA INSTITUTE, at 4.30.—The Early Celtic Church of Britain and Ireland: Eleanor H. Hull.

TUESDAY, MARCH 20.

ROYAL INSTITUTION, at 5.—The Influence of Geology on Scenery: Dr. J. E. Marr, F.R.S.

ZOOLOGICAL SOCIETY, at 8.30.

ROYAL HORTICULTURAL SOCIETY, Scientific Committee, at 4.—Mendelian Laws of Inheritance: Charles C. Hurst.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Outer Barrier, Hodbarrow Iron Mines, Millom, Cumberland: H. Shelford Bidwell.

MINERALOGICAL SOCIETY.—On the Occurrence of Linarite and Caledonite in Co. Wicklow: Arthur Russell.

WEDNESDAY, MARCH 21.

SOCIETY OF ARTS, at 8.—Motor Boats: Bernard B. Redwood.

GEOLOGICAL SOCIETY, at 8. The Chalk and Drift in Möen: Rev. Edwin Hill.—On the Relations of the Chalk and Boulder-clay near Royston (Hertfordshire): Prof. T. G. Bonney, F.R.S.—Brachiopod Homœomorphy: Pygope, Antinomia, Pygites: S. S. Buckman.

ENTOMOLOGICAL SOCIETY, at 8.

ROYAL MICROSCOPICAL SOCIETY, at 8.—A Contribution to our Knowledge of the Rotifera of South Africa: C. F. Rousselet.—On the Resolving Limits for the Telescope and the Microscope: E. M. Nelson.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—South Africa as seen by a Meteorologist: Dr. H. R. Mill.

THURSDAY, MARCH 22.

ROYAL SOCIETY, at 4.30.—*Bakerian Lecture*: Recent Advances in Seismology: Prof. J. Milne, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Electrical Equipment of the Aberdare Collieries of the Powell Duffryn Co.: C. P. Sparks.—Electric Winding considered Practically and Commercially: W. C. Mountain.

ROYAL INSTITUTION, at 5.—Internal Combustion Engines: Prof. B. Hopkinson.

FRIDAY, MARCH 23.

ROYAL INSTITUTION, at 9.—Imperial Defence: Lord Roberts.

PHYSICAL SOCIETY (University College), at 5.—On Unilateral Electric Conductivity over Damp Surfaces: Prof. F. T. Trouton, F.R.S.—The Construction and Use of Oscillation Valves for Rectifying High Frequency Electric Currents: Prof. J. A. Fleming, F.R.S.—On the Use of the Cymometer for the Determination of Resonance Curves: G. B. Dyke.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Waves: F. K. Stevens.

SATURDAY, MARCH 24.

ROYAL INSTITUTION, at 3.—The Corpuscular Theory of Matter: Prof. J. J. Thomson, F.R.S.

THE BANTU SPEECH OF SOUTHERNMOST AFRICA.

A Grammar of the Kafir Language. By J. McLaren, M.A. Pp. xiv+240. (London: Longmans, Green and Co., 1906.) Price 5s.

A FAIR-MINDED critic would start a review of this work by a general verdict of praise for its compactness and usefulness. It is an excellent grammar of the Kosa[1] language of that southernmost group of Bantu-speaking negroes known unfortunately by the most inappropriate term, the Arab word Kafir, or "Unbeliever." The group of Bantu peoples who inhabit the coastlands of the southern extremity of Africa, between the Transkei River in Cape Colony and Inhambane in the Portuguese Province of Moçambique, had better be styled generically "Zulu" rather than "Kafir" or "Kafir-Zulu."

The name Kafir (which, if it is still to be used, had better be spelt as in Arabic with the single "f") is derived from the Dutch Caffer and the Portuguese Cafre, and these again from the language of the Swahili Arabs whom the Portuguese encountered as the masters and traders of South-eastern Africa in the beginning of the sixteenth century. These Arabs, who radiated from Zanzibar northwards and southwards, called all the negroes south of the Zambezi delta "Kafir" in the singular and "Kufar" in the plural, and by this name they spoke of them to the Portuguese, who at first made use of the Zanzibar Arabs as pilots and guides along the eastern coast of Africa. The Cape Dutch borrowed the term from the Portuguese, and so passed it on to the English.

The great Zulu race at the present day is divided into three main branches so far as language or dialect is concerned—the *Ronga* or *Tonga* section of South-east Africa (including the Abagaza), between Amatongaland and Sofala; the *Zulus* of Zululand, with their outlying colonies and offshoots in Swaziland, Matabeleland, and across the Zambezi (through British Central Africa to German East Africa); and the *Kosa* Kafirs of Western Natal, Pondoland, and the Transkei territories of Cape Colony. The difference between the Zulu and Kosa dialects is much less than between Zulu and Shi-ronga. Naturally, the Zulu speech that has been dropped down here and there in little colonies in East-Central Africa north of the Zambezi is already departing widely from the Zulu in Zululand, owing to intermarriage with local races.

The original place of origin in Central Africa of the Zulu-Kafir peoples and dialects is still an unsolved mystery; their nearest relations at the present day in vocabulary and grammar (though not in phonology) are the great Basuto group of Central South Africa and the Damara (Ova-herero) of South-west Africa. There is not that marked relationship with the existing tongues in Central Zambezia which one would expect to find, though, of course, as these are equally "Bantu" in form and construction they offer a good deal of resemblance to Zulu, but not more so than is shown by the other Bantu languages of East Africa. Here and there in the dialects of Lake Nyasa and even of the tongues of inner East Africa there are hints of resemblances to the Zulu group in vocabulary. At the same time, many of the peculiar features in vocabulary and grammar of the Zulu language and its kindred dialects are only to be met with elsewhere in the Se-suto forms of speech, and perhaps in the Ochi-herero. The Zulu-Kafir language group offers some archaic features in the form of its prefixes and of certain word-roots. But it is *not* the "Sanskrit of the Bantu," nor nearly so archaic as the languages round Tanganyika and the Victoria Nyanza.

One of the most marked peculiarities of Zulu and Kosa Kafir is the possession of three "clicks." The Shi-ronga dialects of South-east Africa, though closely related to Zulu in vocabulary and grammatical structure, do not possess these clicks, and no trace of them is met with in Se-suto or Ochi-herero, or indeed in any other Bantu language. The general assumption is that the clicks have been borrowed from the Hottentots, and, of course, in the case of the Kosa Kafirs this is conceivable, as for centuries they have bordered on the Hottentot domain. Yet it is rather extraordinary that the Basuto peoples, who in history certainly preceded the Kafir-Zulu in the invasion of South Africa, and who, as may be seen by their physical appearance, have anciently inter-bred with the Hottentots, should not have borrowed any click from Hottentot or Bushman. Likewise the Ova-herero and their allies have been in close contact with Hottentot peoples in South-west Africa without catching the infection of the click. Miss A. Werner, one of the few serious students in Great Britain of Bantu languages, has written several articles on this subject, without, however, arriving at a definite conclusion as to whether the Zulu-Kafir clicks are borrowed from Hottentots or are independent developments of the language, recently acquired *in situ*. The author of the work under review seems to suggest that the three Zulu-Kafir clicks may be explosive pronunciations of the gutturals. If so, they might have developed separately without Hottentot influence.

It is a pity in the work before us that the author has not had the courage to quit South African provincialism and aim at bringing his grammar into accord with the approved classification of the Bantu languages, and a system of spelling, such as that of Lepsius, which is both scientific and logical. A strong man should come forward, and, by his influence, compel all philologists, the whole world over, to adopt the Lepsius alphabet (with two or three trifling changes) as the standard which all persons must adopt in transcribing the languages of the world not already and anciently expressed in Roman letters; nay, more, it is to be hoped one day that all the civilised tongues of the world—English, French, German, Russian, Greek, Arabic, and every other speech with a literature—may be written down in one form of lettering, and according to one standard—perhaps the Lepsius—of expressing sounds by letters.

Meantime, some uniformity of transliteration might

[1] It is more convenient to write this word, which begins with a lateral click [=//osa], with a K. It is usually spelt Xosa in South Africa.

well be enforced in Africa. As it is, there is one method adopted in the Western Congo, another in South Africa, a third in East Africa, and a fourth in West Africa and the Sudan. Mr. McLaren, in the Kafir grammar under review, adopts the South African standard; the three clicks which Lepsius expresses by */*, *!*, and *//* are rendered (as they have been for half a century) by *c*, *q*, and *x*.

Now throughout Eastern Africa, *c* or *ch* is used to express the palatal consonantal combination of *tṣ* which in South Africa and many West African missionary grammars is rendered by *tsh*; *q* is universally used in North, North Central, and Western Africa (besides by Lepsius) to transliterate the Arabic ق—*qof*, a very explosive *k*, the old meaning of the Mediterranean *q*. *X* is used by the Congo missionaries (following the Portuguese) as an equivalent for the English *sh* (*ṣ*), and by others as a convenient form of the Greek χ to express the strong guttural *kh* (Scotch and German *ch*). On the other hand, *kh*, *sh*, and *zh* in transliterations into Roman letters of Hindustani and Arabic names are intended to be pronounced literally like an aspirated *k*, *s*, and *z*. It is therefore necessary for a logical orthography to adopt *c*, *q*, and *x* for the purposes above mentioned, namely, to represent the English *ch*, the Arabic ق and the Greek χ. Therefore it would be preferable to render the South African clicks by other signs, such as those proposed by Lepsius.

For the practical purposes of those who wish to acquire the Kafir language or arrive quickly at an understanding of its main features, Mr. McLaren's grammar may be very highly commended.

H. H. JOHNSTON.

MINING LAW.

Mining Law of the British Empire. By Charles J. Alford. Pp. xii+300. (London: Charles Griffin and Co., Ltd., 1906.) Price 8*s*. 6*d*. net.

ALTHOUGH admirable treatises on mining law for the guidance of lawyers have been written by Rogers, Walmesley, McSwinney, Bainbridge, Cockburn, and numerous foreign authors, the field has by no means been exhausted; and Mr. Alford's work forms a welcome addition to technical literature. Written with conspicuous literary skill by a mining engineer of wide experience, it gives a concise summary of the various codes of mining law of the British possessions throughout the world, with well considered remarks on their characteristics. The term mining law is taken by the author to mean the enactments that regulate the acquisition and tenure of mining rights. Mining regulations, which control the methods of working mines, receive merely incidental mention. In the case of Great Britain, it is true, the Mines Regulation Acts are quoted at some length as models; but even in this case no reference is made to the Amendment Act of 1903 or to the numerous special statutes, of which fourteen are cited in Sir C. Le Neve Foster's "Ore and Stone Mining," that affect miners and workers in open pits in this country. Indeed, Mr. Alford's chapter on the mining law of Great Britain is the least striking in the book. Mining in Great Britain is so largely a matter of contract between lord and lessee, and so largely concerned with non-metallic minerals, that there is little scope for the comparative treatment of the metal-mining rights and obligations that forms so interesting a feature of the chapters dealing with colonial laws.

The historical study of the inception of mining law receives, as is to be expected in a book of a purely practical character, only brief mention, and the author has refrained from the temptation of citing the ancient statutes set forth in that delightful old work on mining law, the "Fodinæ Regales" of Sir John Pettus, Knight (1670). Originally, the author tells us, the minerals of the country were worked by slaves or serfs for the benefit of the lords of the soil; and Mr. Alford would have added to the interest of his note on the free miners had he mentioned the fact that the last native-born Briton who was a slave in Great Britain, died in the reign of Queen Victoria. When the Queen ascended the throne, many men and women were still living who had in their youth borne a legal bondage in the collieries of Scotland. Such miners received wages, but were not allowed to move away from their master's estate. They were bought and sold with the property; and although they were freed from their servitude by an Act passed in 1799, the slave taint stuck to their occupation for many years.

Mr. Alford divides his work into nineteen chapters, dealing respectively with the principles of mining law, and with the mining laws of Great Britain, British India, Ceylon, Burma, the Malay Peninsula, British North Borneo, Egypt (should not a word of explanation have been given that Egypt is not a part of the British Empire?), Cyprus, the Dominion of Canada, British Guiana, the Gold Coast, Cape Colony, Natal, the Orange River Colony, the Transvaal Colony, Rhodesia, the Commonwealth of Australia, and New Zealand. An analysis of the mining laws cited shows a grouping of the principles of their construction into two classes:—(1) that in which the State or a private owner of mining property has the right to grant concessions or leases; and (2) that in which any individual, under specified restrictions, has the right to locate a certain limited area of ground or claim and to work or to dispose of it. It is surprising to learn that five-sixths of all the mining areas of the world are worked under the former system of titles. The concession system of large prospecting areas, followed by mining leases of limited areas, of which the present mining law of Egypt is an example, appears to be the most advantageous system of opening up an unexplored country.

As an authoritative statement of the conditions of tenure of mining property under various laws, Mr. Alford's book cannot fail to prove of great value to all connected with mining in the colonies. The work is most carefully and accurately done. There are, however, a few slight omissions; and in order to make the survey of the mining law of the British Empire complete, the author might with advantage

add, when a new edition is called for, a few particulars of the mining law of Newfoundland, the oldest British colony, where copper and iron-ore mining are actively carried on; of the West Indies, where, in Trinidad and Barbados, asphalt mining is of some importance; of British New Guinea, where gold mines are worked; and of Nigeria, where some tin ore is raised.

Bennett H. Brough.

ORGANIC CHEMISTRY APPLIED TO PHYSIOLOGY.

Outlines of Physiological Chemistry. By Dr. S. P. Beebe and Prof. B. H. Buxton. Pp. vii + 195. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1904.) Price 6s. 6d. net.

The book deals chiefly with the theoretical side of organic chemistry as applied to physiology. The first chapter, of twenty-one pages, contains an account of the following matters:—dissociation in solution, nomenclature of acids, chemical equilibrium, catalysis, colloids and crystalloids, colloidal solutions of metals, aggregation, suspension and precipitation, oxidation and reduction, osmotic pressure, calculations of a formula, reasons why reactions take place, graphic formulæ, and ultimate analysis.

It need scarcely be added that the space is entirely inadequate to treat of such a heterogeneous collection of chemical problems, even were it profitable to put them in such juxtaposition. The student who has made any study of general chemistry does not need the chapter, and one who has not will scarcely be able to grasp it in the condensed and jumbled form in which it is here presented to him for the first time.

It would hence have been no loss if the book had commenced with the elementary organic chemistry of chapter ii., so as to leave all the space for this, which is the proper introduction to the subject of the book.

A description of the groups of organic compounds most interesting to the physiological chemist is given in chapters ii. to v., of the proteid molecule, its component parts and disintegration products in chapter vi., of enzymes in chapter vii., and an outline of the antitoxin theory, &c., under the title of "Disease and Immunity," forms chapter viii. and concludes the volume.

This latter part of the book is on the whole well and clearly written, but it might be made much more interesting by the authors breaking, even more frequently than they do, their intention of saying nothing about practical work. A description of organic compounds and their relationships, without any statement of what experiments the knowledge of these relationships is based upon, forms only dry and unprofitable reading. For example, it would be much better if the reader were told how the purin bases, or hexone bases, are separated, and would not have taken up a vast amount of space. Without some such instruction, these bodies are only uninteresting names which weary the reader.

The style of the authors is also such as may encourage a too-realistic belief in the mind of the junior chemist in the graphic formulæ which form the organic chemist's rosary. Thus at the opening of chapter v. there occurs the statement, "The chains of C atoms have a tendency to curl over and join at the two ends, forming in this way a closed chain." At another passage in the volume one reads of "the excretion of benzene rings." The account of the chemistry of the proteid molecule is very clear and well arranged, and this portion of the book may be recommended to the physiological chemist interested in the organic chemistry of proteids.

Benjamin Moore.

OUR BOOK SHELF.

Lectures on the Theory of Functions of Real Variables. Vol. i. By J. Pierpont. Pp. xii + 560. (London and Boston: Ginn and Co., n.d.) Price 20s. net.

This is emphatically a text-book, deductive in method and Euclidean in arrangement; as such, it has the defects of its qualities, but its merits are undeniable. In this volume the author deals with the elementary notions of rational and irrational number, point aggregates, function, continuity, differentiation and integration. The subject last mentioned occupies pp. 333–560, so that conditions of integrability, change of order of integration, upper and lower integrals, &c., receive a proper amount of attention. It should be noted, too, that although it is confessedly incomplete, the discussion of maxima and minima of functions of two or more variables is satisfactory as far as it goes, a most unusual circumstance as things are at present. Perhaps the most valuable feature of novelty is that the author occasionally criticises arguments once thought sufficient, but now known to be fallacious, illustrating by examples the way in which the defective proofs break down. This is an excellent way of making a student feel the necessity of mastering the more refined methods of recent analysis. There is one point in which the author has not quite done justice to his authorities. After explaining Cantor's theory of irrational numbers, he gives a brief sketch of Dedekind's method of partitions, but he does not give this in its genuine form. The essence of a partition is that it divides all *rational* numbers (with the possible exception of one) into two classes, each element of one class being less than each of the other. After this definition it is proved that the aggregate of partitions is continuous. Prof. Pierpont (p. 82) defines a partition as dividing *all* real numbers into two classes; this enables him to use Dedekind's notation, when convenient, but it does not give a just idea of Dedekind's theory, and this is a pity. For bibliographical details the reader is referred to the "Encyclopädie der mathematischen Wissenschaften"; this is all very well for those who have access to that work, but in the interests of the student it would be well to give a list of the most important original sources. It ought to be said that in his preface the author acknowledges his special obligation to Jordan, Stolz, and Vallée-Poussin; at the same time it is evident that he has made use of this and other material in an independent way.

Sound and Rhythm. By W. Edmunds. Pp. xii + 96; and Box of Models of the Human Ear. (London: Baillière, Tindall and Cox, 1906.) Price 2s. 6d. net.

This is an admirable little book. The elements of physiological acoustics are described with remarkable lucidity and accuracy, and there is a wealth of illustra-

tion both in the text and in the diagrams. There are chapters on the nature of sound, waves of sound, musical scales, organ pipes, "time" and movement, the ear, and the voice. Nothing could be happier than the exquisite drawings by Miss Martin Mohun showing an ideal couple—a boy and girl—waltzing and drawing sound curves on the seashore. Mr. Lapidge's diagrams are also excellent. To assist the teacher six models, made by Mr. Lapidge, may be obtained for the illustration of the book for one guinea. These models show the structure of the middle ear and the chain of bones. They are accurate in all anatomical details. The box also contains a nightingale pipe, which is in miniature an adjustable stopped organ-pipe. Mr. Edmunds has succeeded in showing how science may be made interesting to young people. There is a constant appeal to observation and experiment, and the whole subject is treated in such a way as to promote the healthy development of the mental faculties in early life. JOHN G. McKENDRICK.

Historical and Modern Atlas of the British Empire, specially prepared for Students. By C. Grant Robertson and J. G. Bartholomew. Sixty-four plates. (London: Methuen and Co., 1905.) Price 4*s*. 6*d*. net.

Philips' Model Atlas. Fifty Maps and Diagrams in Colour. (London: George Philip and Son, Ltd. n.d.) Price 6*d*. net.

The first of these atlases is full of material designed to show students and teachers how intimately the studies of geography and history are related. The excellently executed plates serve as graphic object-lessons demonstrating the interdependence of cause and effect, and are skilfully conceived with a view to impress various important lessons pictorially. The atlas may be commended to the careful attention of both teachers of geography and history.

The sixpenny atlas of Messrs. Philip gives great prominence to photographic relief maps of the countries dealt with, and these plates will prove of great assistance in enabling young pupils to form mental pictures of the distribution of highlands and lowlands in the countries they are studying, thus providing them with a means to understand the direction of flow of rivers, the distribution of rainfall, and other important geographical features. This wonderfully cheap atlas deserves to be used widely in junior classes.

Natural Science in Hygiene, or the Life-History of the Non-Bacterial Parasites affecting Man. By Dr. James Rodger Watson. Pp. vi+62. (Bristol: John Wright and Co.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd., 1905.) Price 1*s*. 6*d*. net.

It is stated in the preface that this little book is intended to place before the student of public health, in a convenient and realistic way, the life-histories of those members of the vegetable and animal kingdoms which by their mode of life are of importance from a public health point of view, and with which he is expected to make himself familiar.

If by "student of public health" is meant the medical man who is going to devote his life to public health, the details given, though on the whole fairly accurate and up to date, are far too meagre and inadequate to be of much service, but the diagrams of life-cycles of the parasites discussed may serve to impress the facts on the memory. The book seems to be more suited to the requirements of the sanitary or meat inspector or health visitor than of the student of hygiene. R. T. HEWLETT.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

A Plea for Absolute Motion.

The title of Prof. Schuster's letter is somewhat wider than its contents. The writer does not discuss whether the term "absolute motion" is significant, but only whether, assuming that the words have a definite meaning, the absolute motion of any body can be determined by physical inquiry. By implication he has himself answered the question in the negative, for at the critical stage of his discussion he introduces arguments which are not physical, but philosophical.

Prof. Schuster asks, "Does it require explanation that all star groups have the same velocity vector imposed upon them?" Certainly; it requires explanation no more and no less than any other distribution of velocities. It is highly desirable that the equations of the proper motions of the stars should be established and their past history traced until the physical circumstance that determined those motions is discovered. But this circumstance need not be a body at absolute rest. In the analogy which Prof. Schuster gives, the inhabitant of a gaseous molecule would be quite wrong if he decided that the rest of the containing vessel was absolute. Accordingly, Prof. Schuster has recourse to philosophical arguments. We have determined, he says, the velocity relative to a material body which does not come within the range of our observations. I should have thought that the mere fact that we had determined a velocity relative to it proved that it had come within the range of our observations; the deduction from the motion of some of the stars of the existence of dark satellites near them seems an analogous case; and since, he continues, this conclusion is absurd, the body must be replaced by something immaterial. Why is it less absurd to determine a velocity relative to an unknown immaterial than to an unknown material substance? Finally, since the something is immaterial, it cannot be in motion, and therefore it must be at absolute rest. The term immaterial may have many meanings; but I should have thought that an immateriality which precluded a substance from being in motion also precluded it from being at rest. A thought, for example, is incapable of motion, but it is equally incapable of rest; any application to it of the terms motion or rest is not true or false, but simply meaningless.

It may also be pointed out that if the "something at rest" is immaterial, the analogy breaks down. The distribution of the velocities of molecules in a gas depends on the collisions with the walls; but a star cannot collide with an immaterial boundary.

Prof. Schuster says that the attempt to make all motion relative to the æther is inconsistent. With all respect, I do not think he sees the point. The reasons for our preference of the Copernican to the Ptolemaic hypothesis are two-fold. The first reason is that the equations of motion of the solar system are simpler on the former theory. The second reason is precisely that which made the theologians object to the Copernican hypothesis; it points out that it is the sun, and not the earth, which holds a unique place in the solar system; this is a question of scientific taste. There are the same reasons for referring all motions to axes fixed in the æther—if we could determine them. Firstly, an attempt is being made to reduce all laws to electrodynamic laws, and these are simplest on the basis of a fixed æther. Secondly, the æther holds such a unique place in the physical universe that it is desirable to direct attention to the fact. The question of the "absolute motion of the æther"—if any—cannot come within the range of physical discussion any more than the "absolute motion of the sun" can come within the range of any discussion based on the properties of the solar system.

I should like to add a few remarks on the subject of "absolute rotation." "Rotation," it seems to me, like

"expansion" or "shear," is not the name of a distinct kind of motion—it is only a term introduced to abbreviate the discussion of a particular and important case of the relative translation of the particles of a body. Direct kinematical statements can only be made concerning particles of infinitesimal volume; such particles can only have translation, they cannot rotate. When bodies of finite volume are considered, they are analysed into particles the motions of which are then investigated. If there is no relative translation between the particles the motion is said to be pure translation; if there is relative translation the motion is said to be partly, or wholly, rotational. It is the characteristic of rotation that two particles situated on a straight line through the "axis of rotation" possess a relative acceleration along that line, and it is by the existence of these accelerations that absolute rotation is detected. If we can find a line such that any two particles situated on a line intersecting it are subject to relative accelerations along the latter, the body is said to rotate. It would be impossible for any observer on a rigid body to detect its rotation, for the relative accelerations of its particles could not be observed. If Foucault's pendulum were rigidly attached to the earth, or if the water in Newton's bucket were frozen, no observers on the earth or the bucket having cognisance of these bodies only could detect the "absolute rotation." In fact, the absolute rotation of bodies of finite volume is only a special case of the relative translation of particles.

NORMAN R. CAMPBELL.

Trinity College, Cambridge, March 18.

Interpretation of Meteorological Records.

THE series of curves given by Messrs. Lander and Smith's instruments, and published in NATURE of March 15, are most interesting, and one cannot help looking for the cause of the close relation between the movements of all the five instruments. It is with the view of offering an explanation of the sympathy between these instruments that the following lines are written. If I might venture to suggest a first cause of these movements, I would say it was the thunderstorm that drew the trigger which started all of them. The thunderstorm gave rise to a heavy fall of rain—a quarter of an inch in a few minutes—and this rainfall appears to have been the cause of the movement of all the instruments, and instead of being placed last in the series should have been put first. The effect of a heavy local fall of rain is to cause a down rush of air, the air being dragged downwards by the falling rain. This downward moving mass of air checks the wind, because its movement is at right-angles to the wind, hence the drop in the wind-velocity curve. The wind not being able to pursue its course gets deflected—in this case the curve shows it was to the north-west. The down rush of air where it meets the surface of the earth has its velocity reduced and direction of movement changed; its pressure is therefore increased, and the barograph shows that the pressure increased by the tenth of an inch. The downward rush of air would bring the air from the upper strata to the surface of the earth, and as this upper air would be in all probability the colder, it would cause a fall in the temperature, which the thermograph shows amounted to twelve degrees.

On one occasion I had an opportunity of seeing this downward movement of air produced by local rain. It was while making some meteorological observations on the top of the Eiffel Tower, in Paris. At first the weather was fine, and the dust-counter showed that the impure city air came to that height in great quantities. After a time a heavy shower came on which reduced the number of particles in the air, and at last the air became as free from dust as any air I have ever tested on the mountain tops of Switzerland. This increase in purity could only be due to the rain dragging down the upper purer air to the level of the top of the tower, as rain cannot wash the air to anything like that purity.

If the time scale of the curves in the instruments had been a good deal wider, and all the clocks going together, one could have found out whether the above explanation was correct or not, as we would expect the rainfall curve to begin first and all the others to follow, but from the closeness of the time scale of the curves no satisfactory information on this point can be obtained.

Ardenlea, Falkirk, N.B. JOHN AITKEN.

Agricultural Education and Colonial Development.

IN your issue of January 11 reference is made to the requirement which has recently arisen for specialists in agriculture and the allied sciences for employment in the British colonies and dependencies. The case, so far as India is concerned, may be stated very briefly. The Government is willing to spend money in the development of agricultural education and research, but the efficient recruitment of the department—or, more properly, departments, for there are eight local governments in India and Burma, each of which will have its own separate agricultural department—is not an easy matter. The educated native of India has not hitherto devoted the interest to the study of agriculture that he has to law and medicine, and men qualified to give instruction or conduct investigations in relation to this national industry are not to be found in the country. It is quite unnecessary to raise the question as to whether they will be obtainable in the future. This is one of the great desires of the Indian Government. In the meantime, however, men qualified to fill the offices above indicated are required, and a search has to be made elsewhere. In this respect, then, India appears to be drawing upon the same market as other countries.

In my view, the description of man that is required is one possessing a thorough knowledge of *principles*. The conditions of tropical agriculture are so very different from those of the British Isles that it is highly desirable for the Britisher to commence work in other continents with as open a mind as possible. I am not thinking so much of the agriculturist as of the botanist, entomologist, or chemist. Just as the chemist who has made himself master of pure chemistry makes eventually the best technical chemist, and finds it, indeed, easier to apply himself to any special technology than the so-called technical chemist, so, likewise, for agriculture in foreign countries, the men who will be most useful in the future will be those who have obtained a thorough knowledge of their particular science at college without any special reference to British agriculture. J. WALTER LEATHER.

Agricultural Research Institute, Pusa, Bengal, February 28.

Peculiar Ice Formation.

IN reply to Mr. James Foulds's inquiry in NATURE (March 15, p. 464) whether the prismatic forms of ice such as he has recently observed in Lancashire have been observed elsewhere, it may suffice to refer him to previous volumes of NATURE, more particularly to vols. xxxi. and xlvii., for letters from Messrs. Woodd-Smyth and McGee, also from myself. In the latter volume is an account by me of a more extended series of observations on these "crystallites" than previous observers appear to have made. Friability of soils is due to interstitial water.

Bishop's Stortford, March 16. A. IRVING.

I OBSERVED the same formation as that described by Mr. Foulds (p. 464) on bare soil, previously soaked with water, near Champéry, in Switzerland, as winter frosts began; and I believe that I have observed it everywhere as a common phenomenon.

I take it that the wet surface is first frozen, and that, as the cold penetrates, the ice exudes from the soil much as lanoline exudes from a lanoline tube, the water expanding as it freezes, and so forcing its way out between the more compact masses of soil, lifting the frozen surface-sheet.

The first touch of sun caused the structure to break up.

It struck me at the time that this was the cause of the injurious effect of frost on the surface of roads considered from the cyclist's point of view. W. LARDEN.

Devonport, March 16.

AMERICAN OBSERVATIONS OF THE TOTAL SOLAR ECLIPSES OF 1900 AND 1901.[1]

IN the year 1900 the moon's shadow swept across the southern portion of the United States of America, travelling from New Orleans, through Georgia, South and North Carolina, and leaving this continent at Cape Henry, in Chesapeake Bay. After traversing the Atlantic Ocean the shadow crossed Spain, and cut the African coast at Algiers.

The large strip of country in America over which the shadow passed drew a great number of American observers to this region, and in a volume which has quite recently been published we have a detailed account of the observations and photographs.

For the main part, this valuable addition to eclipse literature deals with the observations made by the Naval Observatory, which equipped two stations on the central line, one in North Carolina and the other in Georgia, the intention being to duplicate the work in order to minimise the danger of unfavourable weather. Since, however, a large number of other parties with varied equipments was scattered along the line of totality, the reports of several of these have been included in a separate section of this volume.

The stations fixed upon by the Naval Observatory's parties were two in the State of Georgia, namely, Barnesville and Griffin, and one in North Carolina, Pinehurst being the location selected. The reason why two stations were chosen in the former State was because it was desirable to concentrate the spectroscopic attack on the chromosphere near the end of the shadow track, Griffin being the region where the lower strata of the sun's atmosphere during totality were exposed longer to view. Griffin was twenty miles distant from Barnesville. Prof. Updegraff was placed in charge of the Georgia stations, while Prof. Skinner superintended the work at Pinehurst.

Fortunately the weather was very favourable at all the stations, so that the results here brought together are numerous and very complete. First, as regards the instrumental equipment at each of the stations. Space does not permit reference to the instruments in anything like detail, but the reader will find in the volume all the information clearly set out. The general scope of the work undertaken will, nevertheless, be gathered from the following brief summary concerning the chief instruments employed.

Barnesville.—This station was chiefly used for photographing the corona. The largest instrument employed there was an object-glass of 4-inch aperture and 40-feet focal length, the tube being pointed directly at the sun at eclipse time. The image formed was 4.36 inches in diameter.

Another instrument consisted of a battery of cameras mounted on a wooden polar axis 11 feet long and moved by a clepsydra. The cameras erected on this were as follows:—three lenses of 6-inch aperture having focal lengths of 104, 80, and 33 inches; a 4-inch Dallmeyer lens of 17-inch focal length; and a 3.5-inch Dallmeyer of 9.5-inch focal length.

In addition, there were two 5-inch equatorials for visual observations and a prism-spectrograph.

Griffin.—At this station the attack was made from the spectroscopic point of view. Here were located a 10-feet concave Rowland grating worked in conjunction with a 3.5-inch quartz lens and a cœlostat; the plates used were placed in curved backs, and the first-order spectrum was employed. There was also a large Rowland concave grating of 21.5-feet radius, worked also in connection with a quartz lens and cœlostat, but mounted after the method of Rowland. This was employed chiefly for the ultra-violet in the second-order spectrum.

Pinehurst.—Here was erected a 5-inch 40-feet coronagraph pointed directly at the eclipsed sun. Worked in connection with three independent cœlostats were:—a plane grating objective spectrograph with ruled surface 3.5 × 5 inches (15,000 lines to an inch); a concave (10-feet) grating slit spectrograph similar in ruling and size to the plane one; and a 4-inch prismatic camera with one flint glass prism of 60°.

As at Barnesville, a large polar axis was here erected to carry several cameras, and two Dallmeyer lenses of 38-inch focal length and a Voigtländer lens were mounted on it. Three equatorials for visual observations and a transit instrument completed the equipment.

FIG. 1.—The coronas of 1900 (upper) and 1901 (lower) as photographed by the U.S. Naval Observatory parties. (The north point of the sun is at top of each.)

In the volume before us the results obtained with each of the several instruments are individually discussed, and on the whole they have turned out very satisfactory. Further, the volume is illustrated, not only by a series of excellent reproductions from photographs of the camps and the instruments *in situ*, but of the forms of the corona and the chromospheric

[1] "Publications of the U.S. Naval Observatory." Second Series, vol. vi, appendix i. By Rear-Admiral Colby M. Chester, U.S.N., Superintendent. Washington, 1905.)

spectrum. All these will be of great interest to other observers of the same eclipse, as comparison of results is of great importance in the interest of future eclipse work.

It would lead one too far, and, indeed, it is not necessary, to enter into the very complete treatment here published of the various branches of work so well brought together, but perhaps a word or two may be mentioned with regard to some expectations that were not so successfully realised as was hoped.

In the case of the 10-feet concave grating erected at Griffin, the plates turned out to be very much under-exposed. In explanation of this, Prof. Crew not only summarises the possible causes of failure, but adds some useful suggestions for use on future occasions. In the case of the former he mentions seven possible causes, the first being that the intensity of radiation of the eclipsed sun was underestimated, and consequently only the very brightest lines of the chromospheric spectrum were recorded. The second was that the effect of astigmatism in the curved grating was underestimated.

A third reason was that an exposure of two plates instead of one during totality was more than was justified by the dispersion and slit width.

In Mr. Humphrey's report relative to the 21.5-feet Rowland grating at Griffin, a very dissatisfied tone is pronounced with regard to the instrument's efficiency. He finally states:—"It does not seem probable, however, that a grating mounted according to the Rowland method and used with a slit can, even under the most favourable circumstances, yield nearly as many flash lines as may be obtained with a prism or a concave grating used directly without lens or slit. . . . It would be well in using a spectrograph of this kind to avoid the chromatic aberration of lenses entirely and to form the image on the slit by means of suitable reflectors. It might also be best to use silver reflectors and to avoid that part of the ultra-violet of wave-length shorter than λ 3600. Direct grating or prism spectrographs should be used, if possible without reflectors of any kind, but when a reflector is used it should consist of magnalium for the ultra-violet and of silver for light of longer wave-lengths."

With regard to the plane grating spectrograph used at Pinehurst, Mr. Jewell states that the definition of the lines was good from wave-length 3850 to 4100, and "remarkably fine near the H and K lines." The definition between 3750 and 3850, and from 4100 to 4200, is described as "fair," but "very poor" at wave-lengths less than 3700 and greater than 4200. A complete and long table of wave-lengths of the chromospheric lines measured is given in the report.

The coronal lines observed were six in number, the mean wave-lengths of which were as follows:—3382.4, 3453.3, 3644.0, 3801.8, 3987.5, and 5304.1. The objective prism spectrograph at the same station also secured chromospheric and coronal spectra, and although a long list of the wave-lengths of the lines is published, great weight cannot be given to their accuracy, since the definition on the negative is described as "poor over the whole spectrogram and particularly poor for the violet end."

Although no word has yet been said about other branches of work taken up, the reader must be referred to the volume itself for the numerous reports on them. We reproduce in Fig. 1 (upper part) a picture of the corona as photographed with the 40-feet camera at Barnesville, the exposure of which lasted thirty-five seconds. It will be seen that it illustrates well the "wind-vane" form typical at epochs of sun-spot minimum. The lower part of this illustration shows the corona of 1901, taken also with the 40-feet instrument. Fig. 2 shows a general view of the station selected at Pinehurst, the method of supporting the 40-feet coronagraph, and the houses for the other instruments erected there.

FIG. 2.—The U.S. Naval Observatory Eclipse Station at Pinehurst, North Carolina. The 40-foot Coronagraph is on the left.

The second portion of this important volume deals with the observations made during the solar eclipse in Sumatra in May, 1901, the stations selected being Solok, Fort de Kock, and Sawah Loento. At the first station clouds reigned supreme during totality, but the chromosphere was photographed at third contact through clouds. At the second station the weather is described as "perfect," while the observers

at the third station only managed to obtain some results at third contact, the weather being very unfavourable.

At Fort de Kock, in addition to some beautiful corona pictures (one of which is here reproduced for comparison in Fig. 1) taken with the 40-feet coronagraph, used horizontally in this eclipse, photographs were secured with the 30-feet concave grating. In the latter, films were used in consequence of the sharp curve in the focal plane of the grating, but, as the report says, "each film showed that, unfortunately, it had not been placed exactly in focus, still the dispersion was so great that many of the lines could be very easily identified." A table is given showing the results obtained from the measures of these negatives, the spectrum covering λ 3118·5 to λ 5204·7; intensities, character, and wave-lengths from Rowland's tables are also included.

At Sawah Loento the plane grating proved a success, parallel rays falling on its surface and being brought to a focus on the photographic plate by means of a lens placed between the grating and the plate. In spite of clouds, the negative taken at third contact is said to have been fully exposed. The large dispersion employed and the definition obtained allowed very accurate wave-lengths to be deduced, so that the table of wave-lengths extending from λ 3835·2 to λ 4957·8 will be very valuable to compare with those made by other observers.

The discussion of these results is here carried to some length, but space does not permit of any extensive reference. It may, in the first place, be said that both Mr. Jewell and Dr. S. A. Mitchell record having observed the magnesium (λ 4481) line in the photograph of the chromospheric spectrum, and both agree in the determination of the wave-length, intensity, and length of arc. It is described as being stronger in the chromospheric spectrum than in the ordinary solar spectrum. The presence or absence of this line in the chromospheric spectrum is a point of such great importance that the observation above described requires to be very carefully corroborated before it can be finally accepted. It is, however, very difficult to understand how the above identification of the magnesium line with the chromospheric line has been obtained, because in the list of wave-lengths here published the evidence seems to point to a titanium origin. Thus we find in this table that the wave-length of the chromospheric line, as measured, is λ 4481·4, while the solar lines nearest this are, according to Rowland, λ 4481·298 (Mg) and λ 4481·438 (Ti). Further, has it been definitely established that the solar line λ 4481·298 is due to magnesium?

It is also stated that it seems probable that the more volatile gases of atmospheric air uncondensed at the temperature of liquid hydrogen, together with hydrogen, helium, neon, and argon, are present in the chromosphere, but with regard to krypton and xenon the evidence is not conclusive. These deductions also do not seem to be supported by sufficient evidence, but will require further discussion before they can be generally accepted.

Enough, perhaps, has been said to indicate to the reader the importance to the study of solar physics of the publication of such a volume as this. Here we have all the data and discussions relative to two eclipses brought together under one cover, rendering a comparison of results a matter of little labour. One blemish we may, however, remark, and that is that the corona reproductions are not oriented in any way.

It may be still in the minds of our readers that, for the observation of the recent eclipse of 1905, Admiral Chester, Commander-in-Chief U.S. Eclipse Squadron, was in command of four men-of-war told off for eclipse work in Algeria and Spain. Their "station bills," showing the staff at each station and the work to be accomplished, gave one a good idea of the thoroughness with which the undertaking was organised. We shall at any rate look forward to another such volume as this, with, we hope, equally successful results. WILLIAM J. S. LOCKYER.

AGRICULTURE AND THE EMPIRE.

NATURE for January 11 contains a short paper on a large subject. Seeing that the cultivation of the soil, or agriculture, is the fundamental condition of human existence with any approach to civilisation, large is a very moderate description.

I take it that the object of the writer was to discuss the part that the Home Country should play in advancing agriculture in the Empire at large. That is a matter which seems to me important enough to receive a little discussion. It is one with which I have been a good deal occupied during the past thirty years. I should like, therefore, to attempt to define the present position of the problem a little more precisely.

May I begin with a very obvious remark? Agriculture is a sort of "noun of multitude." There is undoubtedly only one agricultural science based on physiological principles; there are many agricultural "arts" based on the application of that science, whether empirical or otherwise, to widely different physical conditions. The agriculture of the Lothians differs widely from that of Bengal, and both differ from that possible on the Gold Coast. This will seem to many an absurdly trite remark. Nevertheless, experience shows that it represents a fact which has often been overlooked, with loss and disappointment as the result.

It may, I think, be confidently stated that arable cultivation has been brought in the British Isles to a pitch of perfection which is not surpassed anywhere in the world. It is, however, an "intensive" and highly specialised agriculture. This is readily illustrated by the yield of wheat per acre. On land of prairie value, where the nitrogen removed is balanced by that received from the atmosphere, it has been shown at Rothamsted that the yield is roughly some 10 bushels or less. This actually represents the state of things in the great wheat-growing countries from which we draw our supplies—Argentina, Australia, India and Russia—and the United States with 13 bushels are not much better. The yield of the United Kingdom for the five years preceding 1904 was 31 bushels, and this was only surpassed by that of our antipodal colony New Zealand, 32.

This is largely due to the scientific research in agriculture for which, I think, it may be fairly claimed this country has always been preeminent. I by no means think that it is exhausted. I remember Sir John Lawes saying to me that, having devoted half a century to the study of the soil actually cultivated, he was still absolutely ignorant as to the subsoil and the part played by it. Our knowledge of the action of manures is mainly empirical, and we have still to learn much of its physiological significance. Without this it cannot be said that we possess a rational theory of manuring. Farmers must have wasted enormous sums in the application of nitrogenous manures until Frankland showed that a considerable proportion passed off unused in the drain-water.

I must confess that I am not clear that the arable agriculture of the United Kingdom is in a backward condition, that it does not compare favourably with that of other countries, or that it stands in urgent

need of Government aid in regard to research. Its theoretical principles can be taught in our universities and schools; its practice can only be learnt on the farm. While saying this I must also express my conviction that the agricultural wealth of this country might be increased in many ways. In my evidence before the recent departmental committee on fruit culture I expressed a strong opinion that the condition of that industry was in no way creditable to us.

At the moment, where, so to speak, the shoe pinches is not above but below. There is no dearth of scientific knowledge in the country, but it floats on the surface and does not permeate. The scientific and even practical ignorance of the small cultivator is profound. The Board of Agriculture and Fisheries has tried to grapple with this by the wholesale distribution of carefully prepared leaflets. But such a method of disseminating knowledge is of almost heart-breaking difficulty. I have had prepared at Kew a series of diagrams illustrating the diseases of trees, suitable for schools. The *Daily Graphic* was good enough to say that:—"This publication is equal to the very best of those ever sent out by the United States Department of Agriculture." Yet the sale has been disappointing, and the Board of Agriculture and Fisheries does not see its way in consequence to proceed with the further and still more needed series dealing with the diseases of fruit trees. The crying need, in my judgment, at the moment is the introduction of intelligent cultural instruction into rural elementary schools.

If we turn to India we have to face a difficult problem. The revenue is dependent on the land, and this in turn has to support a constantly increasing population. It has been supposed that this might be met by the use of British methods. But how? Sir James Caird, who was sent out to study the problem on the spot, reported that if the produce of the land could be increased by 1 bushel per acre, all would be well. No doubt; but how is this intensive cultivation to be accomplished? Long cultivation has brought the land down to a condition of nitrogen-equilibrium. Dung is used as fuel, and the cultivator is too poor to import artificial manures.

In 1900 I attended a conference at the India Office on the qualifications of an Inspector-General of Agriculture. The report of the proceedings is printed in the Blue-book of the Botanical Work Committee (pp. 77–78). I stated then, and the statement met with general assent, "It would be the greatest mistake to substitute for Indian agricultural practices western methods, merely because they had succeeded in the west. . . . The problem in India was how best to graft the results of scientific agricultural knowledge on to the stock (the really valuable stock) of Indian agricultural practice and experience."

India has long had experimental farms in plenty. They have not been without their usefulness. But they have lacked permanence and a guiding principle. It now owes in great measure to the munificence of an American gentleman an agricultural research institute at Pusa. It is further, I believe, intended to establish a number of subordinate stations at a cost of 250,000*l*. If these are to be staffed from home *forthwith*, the result will be very much what the Transvaal Director of Agriculture points out. The Government of India should at once make up its mind what appointments it proposes ultimately to make, and inform the universities at home five years in advance. Students at the universities cannot be expected to engage in agricultural or allied studies unless they see clearly what is to come of it at the end.

Let me turn now to the problem presented by the West Indies and other of our tropical possessions. Sir Daniel Morris is quoted as saying in regard to the former:—"Agricultural education is at the root of the successful development of these Colonies." This is perfectly true, only I rather doubt whether the writer of the article quite understood the reason. In temperate countries agriculture is a necessity of existence; in many tropical countries it is not. The wasteful production of a few ground provisions calls for the minimum of effort, and is sufficient to sustain indolence. But with the introduction of orderly government a revenue becomes necessary. Sir Charles Bruce has laid it down that "in the Crown Colonies generally . . . the only taxable fund is the wage fund supplied by the annual proceeds of the cultivation of the land" (Proc. Colonial Institute, vol. xxxvi., p. 248). To induce the negro to engage in profitable cultivation instead of contenting himself with a bare modicum of ground provisions provides a source of revenue, raises his standard of comfort, and makes for his moral progress. But he has to be taught by example how to do it, and this is the agricultural education which Sir Daniel Morris had in his mind. It is widely different from anything of the kind in this country.

In point of fact, tropical agriculture has little relation to that of temperate countries. Its methods are those of horticulture; it is essentially extended gardening. For the supply of men for this purpose our agricultural colleges would be of little or no use. The problem has had to be met in a wholly different way. The machinery for the purpose is compendiously described in the following extract from the Colonial Office List (p. xx.):—"'Botanic Stations' . . . are small and inexpensive gardens, devised in 1885, in order to afford practical instruction in the cultivation of tropical crops, and were intended to develop the agricultural resources at first of the smaller West Indian Islands, and subsequently (1887) of British possessions in Tropical Africa. Each is in charge of a Curator, who is a gardener trained at Kew."

The sort of success that has attended the system may be illustrated by a single example. Cacao was introduced to the Gold Coast from Kew. In 1891 the export was valued at 4*l*. In 1900 I was able to exhibit at the Paris Exhibition from the botanic station the first sample, to the best of my belief, grown on the African continent, when it received a bronze medal. In 1904 the export had risen to a value of more than 200,000*l*. In effect, cacao is exchanged for imported goods; besides thus adding to the comfort of the cultivators, it enables them to pay the taxes necessary to maintain peaceful government.

For work of this kind the Empire has to depend on Kew, which is organised for the purpose as an advanced horticultural school. At the present moment some seventy Kew men are in official employment and carrying on the work I have described in our various tropical colonies and possessions.

But besides native peasant cultures British capital and enterprise are also largely embarked in the tropical regions of the Empire in "planting industries." These meet with difficulties which the local Government can and does supply skilled aid to mitigate. Most of the West Indian colonies have a "Government analyst." Cambridge has secured the traditional right to train and supply these. Incidentally they are able to give important aid in dealing with agricultural problems. The value of the work done by Prof. Harrison in British Guiana and Prof. d'Albuquerque in Barbados can hardly be over-estimated.

Ceylon possesses an almost unique staff of trained

experts of every kind at Peradeniya, and a similar organisation is in process of establishment in the Federated Malay States. The rubber industry of the Straits Settlements owes its success to the Director of Public Gardens at Singapore. Besides Pusa, India has experienced botanical experts, all university men, at Calcutta, Madras, and Saharunpore.

Our self-governing colonies know pretty well how to take care of themselves. All possess agricultural departments and produce journals which will compare more than favourably with anything at home. In Canada the Central Experimental Farm at Ottawa is certainly not eclipsed by any institution in the United States. I may be pardoned a little vanity if I remark that when the Transvaal Government applied to Washington for an agrostologist it received a Kew man.

To sum up. What the Home Country can supply to the Empire is :—(1) cultural instructors such as are trained for the purpose at Kew; (2) men with a sound scientific training and a firm grasp of the principles underlying agricultural practice of whatever kind, and for these we must look to the universities. Men who are merely familiar with British agricultural conditions will be mostly of little use unless they possess the flexibility of mind which will apply theory to new and unfamiliar conditions.

W. T. Thiselton-Dyer.

NOTES.

The position of the South Africa medal fund for the endowment of a medal and scholarship or studentship in commemoration of the visit of the British Association to South Africa in 1905 is stated in a circular just issued by Prof. J. Perry, honorary treasurer to the fund. The subscriptions promised or paid amounted to 752*l.*; and to this the council of the British Association has resolved to add the unexpended balance of the special South African fund, amounting to about 800*l.* The following report of the executive committee was adopted at a meeting of subscribers on March 2, and approved by the council of the British Association :—(*a*) That the fund be devoted to the preparation of a die for a medal to be struck in bronze, $2\frac{1}{2}$ inches in diameter, and that the balance be invested and the annual income held in trust; (*b*) that the medal and income of the fund be awarded by the South African Association for the Advancement of Science for achievement and promise in scientific research in South Africa; (*c*) that, so far as circumstances admit, the award be made annually. It is to be hoped that a fund raised for so excellent a project will receive a substantial increase from members of the association who have not already contributed to it, or from subscribers who may wish to add to their subscriptions.

The terrible mine explosion at Courrières, in the Pas de Calais, on the morning of March 10, involving the loss of about 1200 lives, has naturally led to all sorts of conjectures as to the immediate cause. As usual, atmospheric conditions are said to have played a not unimportant part in bringing about the tragedy. In some mysterious way the very low barometric pressure over the North Sea on March 12, two days later, is supposed to explain the disaster. If, however, attention is concentrated on the atmospheric conditions prevailing at the time of the accident, it will be found that they resembled those which have accompanied the majority of the great disasters of the past fifty years. The *Bulletin météorologique de France* shows that during the night of March 9 a well marked anticyclone extended from Spain in a north-easterly direction across France and the Netherlands, so that at 7 a.m. on March 10, when the calamity occurred, the barometer over the Lens district had risen to 765 mm. (30·1 inches); it had, in fact, mounted nearly a quarter of an inch in the course of the night. Obviously, if atmospheric pressure played any part in bringing about the catastrophe, the latter cannot in any way be associated with a low and falling barometer.

The death of Mr. William Sowerby, for many years secretary of the Royal Botanic Society, Regent's Park, occurred at his residence in Hertfordshire on March 9. A grandson of James Sowerby, the famous illustrator of "English Botany" and of "British Conchology," and son of James de Carle Sowerby, another gifted naturalist, Mr. W. Sowerby inherited the family taste for natural history. He was responsible for the drawing of some botanical plates, but early in life he became associated with the Royal Botanic Society through his father, who was a founder and the first secretary, and in Regent's Park he worked for half a century. An observation which brought his name prominently before the public was the discovery of a medusa in the Victoria Regia tank, this being the first record of a medusa in fresh water, not to say in a most unexpected locality. He was keenly interested in economic plants, and not only did he bring together a unique collection, but he obtained fruit and fibre, the latter being distributed on several occasions to commercial men for trial. Among his successful experiments was the cultivation of the white mangrove, Avicennia, that flourished and produced aërial roots in artificial brackish water; he also demonstrated that seaweeds could be grown in tanks in the greenhouses.

It is reported from Tokio that a severe earthquake has occurred at Kagi, in Formosa. Many hundreds of persons have been killed and injured, and a large number of buildings have been destroyed.

A Reuter message from New York states that, according to advices from Honolulu, a volcano in Savaii Island (Samoa) is in eruption on a large scale. Three villages have been completely destroyed, including Maleda. The lava stream is three-quarters of a mile wide, and is flowing into the sea.

Dr. H. C. Bastian, F.R.S., gave a demonstration, with the aid of lantern slides, "On some Heterogenetic Processes," on March 15 at the rooms of the Medical Society. Various micro-organisms were exhibited with the view of meeting the objections that have been raised to Dr. Bastian's interpretations of the transformations observed. An account of Dr. Bastian's remarks is given in the *Lancet* for March 17.

The secretary of the Decimal Association informs us that he has within the past few days received fifty-three promises of support from newly elected members of Parliament. In the last parliament there were 330 members pledged to support the adoption of the metric weights and measures in this country, and at the present time 253 votes can be relied upon in the House of Commons. Additional assents are being received day by day, and it is probable that when the canvass now proceeding has been completed there will be as many supporters in the present parliament as there were in the last.

The report of the late Dr. S. P. Langley, secretary of the Smithsonian Institution, Washington, for the year ending June 30, 1905, shows that much valuable scientific

work is accomplished year by year as a result of the grants made by the institution from the Hodgkins fund administered by it. One such piece of research is that in connection with speech or phonetics, by Dr. E. W. Scripture, who has secured individual gramophone voice records of much historical interest. A voice record of the German Emperor was transmitted by Dr. Scripture in January, 1905, for preservation in the United States National Museum. This record gives, in about 200 words, the Emperor's conception of the aims and beauty of true manhood and of man's duty to his fellow. It is stated that at present only one other record of the Emperor's voice exists, namely, one made at the same time for preservation in the library of Harvard University. Among other important researches aided by the Hodgkins fund may be mentioned the investigations of the upper air currents by means of kites by Dr. A. L. Rotch, of Blue Hill Meteorological Observatory; the experiments conducted by Mr. Alexander Larsen, of Chicago, in connection with the photography of lightning flashes and the fluorescence of minerals; the serial instantaneous photographic study of the flight organs of animals, by Dr. von Lendenfeld; and Prof. W. P. Bradley's experimental investigation of the expansion of air through a nozzle.

The amphipod crustaceans of Catherine Bay, Murman coast, form the subject of an illustrated paper by Mr. E. van der Brüggen published in the last issue of *Trudui* of the St. Petersburg Academy for 1905.

A paper on Californian reptiles, by Dr. S. E. Meek, just issued by the Field Columbian Museum, contains descriptions, with figures, of two species of rattlesnake regarded as new, as well as notes on a number of other snakes and lizards.

We have received from the Field Columbian Museum at Chicago a copy of a "Check-list of Mammals of the North American Continent, the West Indies, and the Neighbouring Seas," compiled by Dr. D. G. Elliot, and issued by the museum. This bulky volume purports to include the names of all species of mammals inhabiting America as far south as Colombia that have been described up to the date of publication. It is, in fact, supplementary to the author's two previous synopses of American mammals.

"The Ideal Thoroughbred Stud" forms the subject of No. 8 of Rural Studies Series, this being the title of a lecture by the Rev. E. A. Woodruffe-Peacock, the well known specialist on soils and grass-lands. With a full knowledge of most large English stud-farms, the author expresses his opinion that there is not one which has not at least some deficiency; and after pointing out the lines on which an ideal stud should be formed, he observes that "the birthplace of a long and steady series of race-winners cannot be a matter of mere chance."

The March number of the *Naturalist* contains an attractive coloured plate representing a pair of bearded tits in their native marsh. The contents include Mr. G. W. Lamplugh's presidential address to the Northern Naturalists' Union at Bradford on January 27, having for its subject the necessity for the amateur spirit in scientific work. Attention is directed not only to the valuable work accomplished by amateurs in the past, but also to the many fields in which their assistance is of the utmost importance at the present day. As an instance, the official geologist cannot possibly devote long periods of time to particular sections or pits, whereas an amateur living in the neighbourhood can easily do so, and thereby is not unfrequently able to solve a problem which has been inexplicable to his professional brother.

The programme of the July conference of the Museums Association at Bristol is outlined in the February issue of the *Museums Journal*. Among the articles is one by Mr. H. Bolton on the future of museums, being the report of a paper read at last year's conference. The author urges the advisability of a Government grant being paid annually to provincial museums of first-class standing, in return for which such institutions should be severally expected to perform a certain amount of allotted work, and in all instances to maintain a high standard of excellence. Another address at the same meeting, by Mr. S. L. Mosley, had for its subject museums and private collections, the author pointing out how much good a private collector can do by working for a museum, and how much harm when seeking his own ends.

In the opening article in the February number of the *American Naturalist* Dr. H. Ayers, taking for his text "the unity of the gnathostome type," urges that there is neither anatomical nor embryological ground for removing amphioxus from the vertebrate class, and that we may class this creature as the sole representative of the Acrania, in contrast to the Craniata, which includes all the rest. Not only so, but the discovery by the author of rudimentary jaw-structures in the lampreys renders the division of the Craniata into Cyclostomata and Gnathostomata no longer tenable. The Gnathostomata must comprise, therefore, the Marsipobranchi as well as all the forms previously included, so that all Craniata are Gnathostomes. The origin of the craniofacial apparatus is thus to be sought in the missing links between amphioxus and the Craniata. Old age in brachiopods, by Dr. H. W. Shymer, and the habits of the American spotted salamander, *Necturus maculosus*, by Prof. A. C. Eycleshymer, form the subjects of the other two articles in the same issue.

Science of February 16 contains a report of an address delivered by Dr. C. H. Merriam, as vice-president and chairman of the zoological section, at the New Orleans meeting of the American Association for the Advancement of Science, on the question whether mutation is a factor in the evolution of the higher vertebrates. As the result of a long practical acquaintance with American mammals, Dr. Merriam is of opinion that there is no evidence of origin by mutation (sudden marked variation) in this class, but that everything points to variation by insensible degrees. Here the author takes occasion to mention that among mammals there is abundant evidence of the gradation of one species or race into another, so much so that specific or racial separation of specimens is often difficult. While admitting that in rare instances species of plants may arise by the perpetuation of "sports," Dr. Merriam states his contention to be that "the overwhelming majority of plants, and so far as known, all animals, originate in the generally recognised way, by the gradual development of minute variations."

It is encouraging to notice the growing appreciation on the part of Government departments and colonial administrators of the benefits to be derived from the application of scientific methods under expert guidance to pearl and other fishery industries. In the proposal to lease the pearl fisheries to a company for a period of twenty years recently laid by the Governor of Ceylon, Sir Henry Blake, before his Legislative Council, it was expressly stipulated "that

a sum of not less than Rs. 50,000 be expended annually on the scientific development of the banks." The Torres Straits pearl-shell fisheries, it seems likely, will also be put under scientific control and cultivation. In a report by Mr. W. Saville-Kent to the Queensland Government (1905) it is shown that the pearling industry to the north of Australia is in a depressed condition due to over-depletion of the natural shell-beds, so that they can no longer be worked at a profit. Mere closure of the beds against fishing is regarded as an inadequate measure, since the remaining molluscs are too few and too scattered to ensure sufficiently rapid propagation to re-populate the ground in a reasonable time. Mr. Saville-Kent recalls what is known of the breeding habits of the animals, and of their suitability for transplantation, and recommends the establishment of at least six "Government pearl-shell breeding reserves" at what seem to be suitable spots in the Torres Straits area. At each reserve about 1000 adult pearl oysters will be kept for breeding purposes enclosed in frames of wire-netting, and Mr. Saville-Kent is of opinion that "within a period of three or four years . . . the adjacent waters within many miles from these breeding centres should be restocked with young shell to such an extent as to permit of profitable fishing." He also recommends the establishment of an experimental cultivation laboratory on the small islet of Wai Weer at Thursday Island, and suggests, further, that a consignment of the Ceylon pearl oyster should be laid down on the Torres Straits ground. It is evident that a good deal in the way of scientific cultivation could also be done by collecting the spat and by cultching the ground, and that regulations may be required in regard to public and private fishing on the beds, and the proper treatment of the stock in the Government reserves. The adoption, before it is too late, of such scientific methods is probably the only way of restoring a depleted pearl-shell industry.

The progress of Indian agriculture has hitherto been recorded in such publications as the Agricultural Ledger issued by the Reporter on Economic Products, or the bulletins circulated by certain of the provincial Governments; and reports on agricultural experiments have been included in official reports dealing chiefly with land records and administrative questions. The existing methods of publication were not suited to the altered conditions produced by the activity of the new department organised by Mr. James Mollison, first Inspector-General of Agriculture in India, and all interested in Indian agriculture will welcome the news that the Imperial and provincial Departments of Agriculture will henceforth publish a "Journal" and "Memoirs." The first number of the Journal has just been issued from the Agricultural Research Institute at Pusa. It is edited by the Inspector-General with the assistance of the Pusa staff, and will be published quarterly. The present number contains an interesting account of the development of the Indian Departments of Agriculture by Mr. F. G. Sly, officiating Inspector-General, and seven articles on questions connected with the cultivation of sugar-cane, cotton, and other Indian staples. The intention of the Government is that the Journal shall deal with agricultural subjects which are of interest to general readers—crops, insect pests, cattle breeding, irrigation, cooperative credit—while in a second publication, to be entitled "Memoirs of the Department of Agriculture in India," scientific work in agricultural chemistry, botany, &c., will be recorded. The Memoirs will be published as separate articles, and these will be arranged in series. Separate series will be issued for each of the chief divisions of science. Both publications will be freely illustrated.

A very valuable report by Dr. A. C. Houston on the bacteriological examination of milk has been issued by the London County Council, with a preface by Sir Shirley Murphy. The report is based on the examination of (*a*) twenty samples of specially selected milk from twenty separate healthy cows; (*b*) twenty samples of milk collected from purveyors' shops; (*c*) twenty samples collected from dairy shops; (*d*) twenty samples collected from churns at railway stations; and (*e*) twenty samples collected from the establishments of well known milk dealers. The samples under (*a*) served as a standard, while those under (*b*) and (*c*) were of milks of indifferent quality, in the main collected from poor neighbourhoods and premises known to be ill-adapted for the sale of milk. The various sources of pollution of milk are enumerated, and an important recommendation is made with regard to a temperature standard, viz. that all milk should be rapidly cooled below 10° C. and maintained at or below this temperature during the whole period of transit and sale in order to prevent the multiplication of bacteria. The following bacteriological standards are suggested:—(1) 1 c.cm. should not give evidence of the presence of *B. enteritidis sporogenes*; (2) 0·001 c.cm. should not give evidence of the presence of *B. coli*. (3) 0·0001 c.cm. should not give evidence of the presence of streptococci; (4) the primary sediments (after twenty-four hours) should not exceed 100 parts per 1,000,000; (5) the secondary sediment (after centrifugalisation) should not exceed 50 parts per 1,000,000. Finally, several reforms which may be considered immediately practicable are suggested for dealing with the milking, the conveyance of the milk, and the vending of the same.

An editorial article in the *Indian Forester* (January) advocates the formation of forest museums in each forest division or in each province that may contain several divisions. In Europe the inception of such a scheme is found in Saxony, where each forest conservator is provided with a set of mounted specimens of the chief insect pests with instructions for dealing with them. In India the credit of starting collections of timber specimens and other forest produce for a conservator's museum is due to Mr. Gass, of the Coimbatore division, Madras. The collections for this division have been extended to serve for the three circles of the presidency, and a special building has been sanctioned for the purpose.

In consequence of the drought that was experienced during the season 1904–5, particularly in Antigua, the experiments arranged by Dr. F. Watts on the chemical selection of sugar-canes in the Leeward Islands failed, but the experiments with different varieties of sugar-cane were carried out. In the report published as a separate part by the Imperial Department of Agriculture for the West Indies it is noted that the six canes giving the best results in Antigua were the same as in the previous year, thus confirming the good character of these canes. The experiments in St. Kitts did not agree so closely with those of previous years, this, no doubt, being caused by the irregularity of the rainfall in different districts.

At a research meeting of the Royal Geographical Society on March 9, a paper was read by Mr. J. L. Myres on the Alpine races in Europe. Rejecting Prof. Keane's theory of a North African origin, Mr. Myres said that the brachycephaly of the Alpine stock might have been de-

veloped locally, or might have immigrated from western Asia, but there was no reason to suppose that the area in which the race occurs in Europe was large enough or secluded enough to account for so considerable a change. The northern or steppe route into Europe was not available until the retreat of the ice-cap and the shrinkage of the Caspian, but south of the Black Sea there was a route, now concealed by submergences subsequent to the period with which he was dealing. In Anatolia the conditions were favourable for the development of a distinct type, and at the same time south-east Europe was partially isolated, and its climate rendered it little suitable for human habitation. *Homo alpinus* was tall in Albania, short in Central France; the dwarf broad-heads developed in south-eastern Europe, where the climate was severe, the giant broad-heads in Anatolia, where conditions were more favourable; and it was natural to find the latter to the east of the former, for they were driven out of Anatolia later, leaving scattered "Dinaric" populations east of the Sea of Azov, and throwing out colonies beyond the "Cevenoles." In favour of this hypothesis were the facts that (1) the fruit-culture of the European lake-dwelling peoples was characteristically Anatolian; (2) physically they were of the right type; and (3) even in classical times Anatolia was noted for this type of dwelling.

At the eighth International Geographical Congress, Mr. R. De C. Ward, of Harvard University, contributed a useful paper on a more rational treatment of climatology. He pointed out that the method of presenting climatic data in the usual tabulated form is unsatisfactory, because it does not bring out the cyclonic variations of different weather conditions experienced from day to day. He does not suggest any change in the recognised order of presentation, but he urges that wherever possible the cyclonic unit should be made the basis of summaries, as well as the diurnal, the monthly, the seasonal, and the annual unit; also that much more attention should be paid to an adequate verbal discussion. Over the greater portion of the equatorial zone, weather and climate are almost synonymous terms, but in the temperate zone, for instance, the regular diurnal changes are very frequently overshadowed by the changes due to the passage of cyclones and anticyclones. The author gives several clear illustrations, *e.g.* in mean monthly and mean annual ranges of temperature we have the sum of both periodic and non-periodic changes which occur during any month, irrespective of the question whether the maxima and minima all occurred under similar conditions, and thus we lose sight of a very important factor in climate; and similarly with regard to rainfall and other elements. More attention should be given to seasonal averages, to departures from the means, and even to the single occurrence of certain phenomena. A tribute is paid to the more rational treatment of climatology as evidenced by the beautiful charts by Dr. Buchan in Bartholomew's "Atlas of Meteorology"; but, valuable as such charts are, the author considers that the various weather elements which, taken together, make up climate should be summarised, not on the basis of the year or month only, but of the cyclone which controls them.

The Journal of the Royal Sanitary Institute (No. 1, 1906) contains an interesting paper by Dr. W. N. Shaw, read before the conference on smoke abatement, and entitled "Is London Fog Inevitable?" The author pointed out that we do not know the actual course of events in the physical processes comprised in the origin and persistence of fog, and referred to two important inquiries made under the superintendence of the Meteorological Council relating to the winters of 1901–2 and 1902–3. In the first report Captain Carpenter came to the conclusion that in winter London was never free from a smoke haze; for some months St. Paul's was invisible from the Victoria Tower at the times of observation, although in the following year conditions were more favourable. The most frequent cause of fog is the cooling of the surface by radiation under a clear sky; there is no limit to the extent of country that may be affected by the formation of fog under this condition. In the second winter, 1902–3, Mr. Lempfert assigned twenty-four cases out of thirty-nine dealt with to the effect of radiation, while eight were considered to consist practically of smoke alone. Thus about 20 per cent. of the London fogs in that year might have been avoided by the abatement of coal smoke, while the remainder depended upon physical processes which are beyond our control. Dr. Shaw remarks that one of the unsolved problems of this interesting subject is why the sun's heat does not dissipate the fog upon which it shines. It was found that the sunshine recorder at Bunhill Row during the month of December lost 83 per cent. of the sun's burning power, that at Westminster 61 per cent., and that at Kew 15 per cent., so that if the sun has any substantial power of dissipating early morning fog, the smoke of the London atmosphere must seriously interfere with its effect. The peculiar manner in which the density varies from place to place, and various other points about London fog, await further investigation.

The Geological Survey of Alabama has issued a revised map of the south-eastern part of the Cahaba coalfield, embodying the results of investigations made since the publication of the original map in 1890. The vertical section shows fifteen seams, mostly of small size, in about 1800 feet of measures.

Statistics of the quantity and value of each of the important minerals raised in India have been published by Mr. T. H. Holland, F.R.S., in the Records of the Geological Survey of India (1906, part i.). Compared with 1903, an increase of nearly 7 per cent. is shown in the total value of mineral production. The production of coal, 8,216,706 tons, exceeded all previous records. There were also produced 3596 tons of chromite, 286 carats of diamonds, 618,746 oz. of gold, 3256 tons of graphite, 3778 cwt. of jadeite, 1315 tons of magnesite, 150,297 tons of manganese ore, 19,575 cwt. of mica, 118,491,382 gallons of petroleum, 265,901 carats of rubies, 1,170,205 tons of salt, 315,558 cwt. of refined saltpetre, and 1388 cwt. of tin ore. Statistics of the production of alum, amber, asbestos, borax, building stone, clay, gypsum, limestone, marble, ochre, and slate are incomplete.

In the Records of the Geological Survey of India (vol. xxxiii., part i.) Mr. E. Vredenburg deals with Pleistocene movement as indicated by irregularities of gradient of the Narbada and other rivers in the Indian peninsula. He gives a very striking photograph of the falls of the Narbada at Dhári. Recent changes in the course of the Nam-tu River, in the northern Shan States, are described by Mr. T. D. La Touche, and the same author gives a note on the natural bridge in the Gokteik Gorge, advantage of which was taken in selecting a site for the railway bridge on the Mandalay-Lashio line. Lastly, Mr. P. N. Bose gives an account of the geology and mineral resources of the Narnaul district, in the Patiala State. The minerals

of economic value met with include iron ores, mica, copper ores, manganese, rutile, as well as limestone and other building stones.

IT has always been a difficult matter to obtain pure lithium by the electrolysis of fused lithium chloride, which has been the method employed up to the present, and was originally used by Bunsen. In the *Zeitschrift fur Elektrochemie* of March 9, Messrs. O. Ruff and O. Johannsen describe a process which they have satisfactorily worked out for its preparation by the electrolysis of lithium bromide. They prepare the lithium bromide by the action of hydrobromic acid on the carbonate. The electrolysing vessel is of copper, and is partially water-jacketed in order that the walls may be kept cool and thus protected by a coating of solid lithium bromide. The anode is of retort carbon, and the two kathodes of iron wire 4 mm. in diameter. The electrolyte consists of lithium bromide containing 15 per cent. of lithium chloride. A current of 100 amperes at 10 volts is employed, and the yield of metallic lithium is about 80 per cent. of the theory. From time to time the metal as it collects on the iron kathode is removed with a flat iron spoon, and at once placed on a cold stone surface, where it rapidly solidifies. Determinations of the melting point showed it to be 180°, which agrees with that found by Bunsen in the middle of the last century.

A SIMPLE arrangement for purifying mercury which is likely to prove of considerable service is described by Messrs. G. A. Hulett and H. D. Minchin in the *Physical Review* (vol. xxi., No. 6). The method consists in distilling the mercury in a Wurtz flask under diminished pressure, allowing bubbles of air to pass through the mercury during distillation so as to prevent bumping. The air also serves the very useful purpose of oxidising any metallic impurity, such as zinc, cadmium, or lead, which otherwise would contaminate the distillate. Ordinary distillation *in vacuo* of mercury containing one of these metals does not suffice to remove the impurity, but by using the method described an amalgam of zinc can be made to yield pure mercury in a single distillation. An electrical method of ascertaining the presence of one part of zinc in ten billion parts of mercury is described incidentally.

THE March number of the *Geographical Journal* contains an interesting table by Miss Nora E. MacMunn, compiled from planimetric measurements made on an orographical map at the School of Geography, Oxford, showing the areas of the orographical regions of England and Wales. As a rule, the plains have been measured to the 250-feet contour line, and the hills have not been considered to begin below that level. The average height of England and Wales, calculated from these measurements, is 385 feet. Of the total 58,324·3 square miles constituting the area of England and Wales, 26,481·6, or 45·4 per cent., are under 250 feet in elevation; 16,364·5, or 28 per cent., are between 250 feet and 500 feet; 10,476·3, or 18 per cent., are between 500 feet and 1000 feet; 4698·3, or 8 per cent., are between 1000 feet and 2000 feet; 300·0, or 0·5 per cent., are between 2000 feet and 3000 feet; and 3·6 are more than 3000 feet above sea-level.

MR. FROWDE is about to publish for the Radcliffe trustees a "Catalogue of 1772 Stars, chiefly comprised within the Zone 85°–90° N.P.D., for the Epoch 1900," deduced from observations made at the Radcliffe Observatory, Oxford, during the years 1894–1903, under the direction of Dr. A. A. Rambaut, F.R.S.

OUR ASTRONOMICAL COLUMN.

DISCOVERY OF A NEW COMET (1906*c*).—A telegram from Kiel announces the discovery of a new comet by Mr. Ross, of Melbourne, on March 18.

Its position at 7h. 36·1m. (Melbourne M.T.) was

$$\text{R.A.} = 2\text{h. } 3\text{m. } 52\text{s., dec.} = \;\; 7° \; 41',$$

which is about half-way between ζ and o Ceti.

A second telegram from Kiel states that Mr. Morgan observed the comet at Glasgow (U.S.A.) on March 19. Its position at 7h. 40·9m. (Glasgow M.T.) was

$$\text{R.A.} = 2\text{h. } 9\text{m. } 31{\cdot}4\text{s., dec.} = -5° \; 47' \; 25''.$$

The comet is stated to be of about the eighth magnitude.

COMET 1906*b*.—Numerous observations of comet 1906*b* are reported in No. 4078 of the *Astronomische Nachrichten*.

Observing at Bamberg on March 4, the day after its discovery, Prof. Hartwig found that the comet had a diameter of about 10″ and a central condensation of about magnitude 11·0. The same magnitude was recorded by Dr. Wirtz at Strassburg on March 6.

Prof. Max Wolf reports that the comet is easily seen on his plates, and shows a tail of about half a degree in length; with the 10-inch refractor a sharp nucleus was observed on March 4, and it was seen that the tail extended to the north-west.

COMET 1906*a* (BROOKS).—In No. 4078 of the *Astronomische Nachrichten* Herr M. Ebell gives a further daily ephemeris for comet 1906*a*, extending from March 16 to May 3. The following is an extract therefrom:—

Ephemeris 12h. M.T. Berlin.

1906	α (true) h. m. s.	δ (true) ° ′	log r	log Δ	Brightness
Mar. 20	5 41 5	+46 31	0·2618	0·1986	0·25
24	5 42 18	+43 47	0·2710	0·2284	0·21
28	5 43 58	+41 23	0·2801	0·2567	0·18
April 1	5 45 57	+39 18	0·2891	0·2835	0·15
5	5 48 10	+37 27	0·2981	0·3088	0·13
9	5 50 34	+35 48	0·3069	0·3325	0·11

Brightness on January 27 = 1·0 = about 10·0 m.

Observing at Arcetri on January 31, Dr. Abetti found that the comet had a central nucleus of about the tenth magnitude or a little greater, and that the surrounding nebulosity extended for about 2′, chiefly towards the direction of lesser right ascension.

On March 22 this comet will pass near to β Aurigæ, about 11m. (R.A.) to the west, whilst on April 5 it will be only about 5m. west of θ Aurigæ.

A PROGRAMME OF SOLAR RESEARCH.—Now that the Mount Wilson Solar Observatory has fairly settled down to work, Prof. Hale has revised his "Programme of Solar Research," published several years ago, and gives an outline of the revised programme in No. 1, vol. xxiii., of the *Astrophysical Journal*.

Two principal studies are to be prosecuted. First, a study of the sun as a typical star, with reference to stellar evolution; secondly, the relationship between solar and terrestrial phenomena.

These studies are divided into five groups, each of which contains a number of subdivisions. The five main groups are:—(1) direct photography; (2) spectroheliograph researches; (3) spectroscopic investigations; (4) studies of the total solar radiation; and (5) allied laboratory investigations.

Most of these are now being prosecuted at Mount Wilson, and Prof. Hale points out that there are many other solar investigations which call for attention, and of which many may be carried out by amateur observers with modest equipments.

HARVARD COLLEGE OBSERVATORY.—Prof. Pickering's report of the work done at Harvard College Observatory during the year ending September 30, 1905, is the sixtieth of the series, and contains the record of an immense amount of work, too much even to summarise here.

One or two special features may, however, be mentioned. Eighteen eclipses of Jupiter's satellites and eight occultations of stars by the moon were observed with the 11-inch Draper telescope. Three of the occultations were photo-

graphed continuously on a revolving plate, so that the nature of the disappearance, whether instantaneous or gradual, could be recorded.

Numerous valuable observations of peculiar stellar spectra were made during the year, including the discovery of Nova Aquilæ No. 2 by Mrs. Fleming. This is the eighth Nova discovered by that observer from the Draper memorial spectrograms.

With the Bruce telescope 523 plates were obtained, making 7504 in all, from which Miss Leavitt has discovered 1129 new variable stars during the year.

The bibliography of variable stars compiled by Miss Cannon was nearly ready for publication when the Astronomische Gesellschaft appointed a committee to undertake a similar work. Prof. Pickering therefore proposes to publish the Harvard work in an abridged form.

CATALOGUE OF 3799 BRIGHT STARS.—A useful catalogue of 3799 bright stars has just been published by M. J. Bossert, of the Paris Observatory.

This catalogue gives the magnitude and mean coordinates (1900·0) of each star, and, in addition, the precession, secular variation, and proper movement, together with instructions and examples for finding the star's position at any given epoch.

The stars are arranged in zones of 1° of N.P.D., and in each zone they are given in order of R.A., this classification being considered the most convenient for meridian observers.

Stars down to the seventh magnitude are included, the magnitude of Aldebaran being taken as 1·0.

ECLIPSE OBSERVATIONS AT CATANIA.—On the occasion of the total solar eclipse of August 30, 1905, observations of prominences, by the Lockyer-Janssen method, and of the variations in the terrestrial electric field were carried out, during the whole day, at the Catania Observatory.

The results are published in No. 1, vol. xxxv., of the *Memorie della Società degli Spettroscopisti Italiani*, and show, among other things, that the maximum effect of the solar radiation corresponds to the minimum potential of the atmospheric electricity.

MICROMETER MEASURES OF STRUVE DOUBLE STARS.—No. 4078 of the *Astronomische Nachrichten* contains the results of a series of measures of eighty-one "Struve" double stars made by Dr. H. E. Lau, of the Copenhagen University Observatory.

The position for 1900·0, the position-angle, the distance, and the data and hour of each observation are given for each star, and are followed by brief notes by the observer.

SOME APPLICATIONS OF THE THEORY OF ELECTRIC DISCHARGE THROUGH GASES TO SPECTROSCOPY.[1]

THE luminosity produced by an electric current passing through a gas at low pressure varies greatly in character, not only when we alter the nature of the discharge, as, for example, when we pass from the arc to the spark, but also in many cases at different points of the same discharge. The luminosity may be of one colour at one place and of a very different colour at another, and spectroscopic examination shows that the spectrum of the same gas often varies considerably as we proceed along the line of discharge. As recent experiments have thrown a considerable amount of light on the processes going on in the different kinds of electrical discharge and at different parts of the same discharge, the study of the connection between the changes in the electrical effects and the changes in the spectra might be expected to throw some light on the very interesting question of the genesis of spectra. Many important points can very conveniently be studied by the aid of Wehnelt's method of producing the current. In this method the kathode is a strip of platinum or a piece of platinum wire on which either a little lime or barium oxide has been deposited. This when heated to redness emits large supplies of corpuscles, and by altering the temperature of the platinum very large variations in the current passing through the tube and in the potential difference between the electrodes can be obtained. In our experiments the current varied from a small fraction of a milliampere to several amperes, and the potential difference from a few volts to several hundred.

The apparatus used is shown in Fig. 1. AB is the platinum strip with the lime on it; a thermocouple—a platinum and platinum-rhodium junction—was fused to this strip, and served to determine its temperature; the strip was connected with the earth, and was heated by a current passing through the leads LM; a rheostat was placed in series with the heating current, and by means of this the temperature could be altered gradually. The anode was a platinum disc; this was connected with the positive pole of a battery of storage cells, the negative pole of which was earthed; to allow of gradual variations in the potential difference between the electrodes a potential divider of 100 resistances of 10 ohms each was used. The current through the tube was measured by a d'Arsonval galvanometer, and the potential difference between the terminals by a Weston's voltmeter.

Some of the most interesting features of the discharge are very prominent when the temperature of the platinum is high, say 1400° C., and the pressure of the gas low, less than 0·01 mm. of mercury. The discharge is light

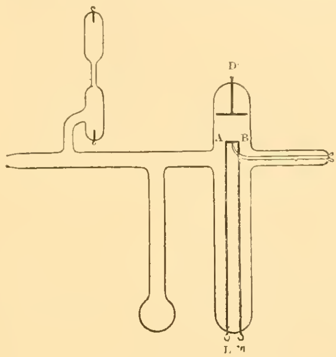

FIG. 1

blue, and its spectrum shows the mercury lines and the band spectrum of nitrogen. In this case the relation between the current and the potential difference is represented by a curve like Fig. 2, the ordinates representing the current and the abscissæ the potential difference. In the case we are considering, when the wire is very hot and the pressure low, the change from the dark to the luminous discharge takes place very abruptly, an increase of the potential difference by 1/100 of a volt being often sufficient to convert a discharge where no light could be detected even in a darkened room into one where the light was quite bright. When luminosity appears there is a very rapid increase in the current; in some of the experiments an increase in the potential difference of 1/100 of a volt increased the current forty-fold. At this stage the thermojunction showed that there was no increase in the temperature of the platinum where the luminosity appeared; we shall see later on that it is possible by using large potential differences to get such large currents through the tube that the platinum becomes appreciably warmer by the passage of the current.

One point which I think very suggestive is the abruptness with which the luminosity round the kathode appears. We see that by a very small increase in the potential difference the discharge passes from a state in which no luminosity can be detected, even in a dark room, to one where the luminosity can plainly be seen in a bright light; thus the molecules of the gas in the tube, just when the luminous discharge is on the point of appearing, are in a state in which a very small change in the electrical

[1] Discourse delivered at the Royal Institution on Friday, January 19, by Prof. J. J. Thomson, F.R.S.

conditions of the tube makes the molecules pass from a condition in which they are not giving out an appreciable amount of light to one where they are brightly luminous, and, as the great increase of the current when the luminosity appears shows, this change in state is accompanied by an emission of corpuscles. From this and other considerations I have come to the conclusion that what takes place when the gas becomes luminous is that the

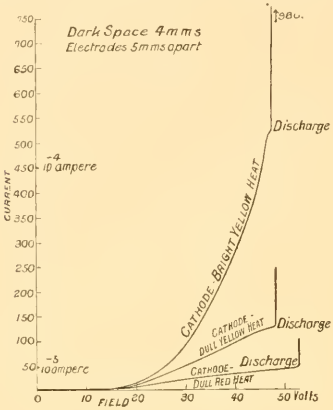

FIG. 2.

internal energy in the atom, in consequence of its bombardment by the corpuscles, increases, and when it gets up to a certain critical value the equilibrium of the atom becomes unstable, an explosion occurs resulting in an expulsion of corpuscles, and such a shaking up of those left in the atom that these vibrate so vigorously that the energy radiated is sufficient to produce luminosity. Thus I regard the ionisation of the gas as being due, not to the corpuscles in the atom being dragged out by the direct action of the electric forces in the field, or as being knocked out by a rapidly moving corpuscle striking against them, but to an explosion due to the atom having absorbed so much internal energy that its equilibrium becomes unstable. Other phenomena point to this as the method by which ionisation is effected. If the corpuscles are dragged out of the atoms by the electric field, the velocity with which they are projected should depend upon the strength of the field; while if they are projected by an explosion their velocity would depend only upon the nature of the atom, and not upon the strength of the field. Now when Röntgen rays fall upon a substance the atoms of the substance are ionised, and corpuscles are emitted forming a stream of kathodic rays. Barkla has lately shown, however, that the penetrating power of the kathodic rays produced in this way is independent of the intensity of the Röntgen rays. Now the electric force in the Röntgen rays depends upon their intensity, and the penetrating power of the kathodic rays depends upon their velocity, so that this result shows that the velocity of the corpuscles does not depend upon the intensity of the force acting upon them. Again, Lenard has shown that the velocity of the corpuscles ejected when ultra-violet light falls upon a metal is independent of the intensity of the light. Lenard also investigated the secondary kathode rays produced when kathode rays fall upon matter, and found that, in addition to rays the velocity of which was of the same order as that of the primary rays, and which may be regarded as deflected primary rays, there were other very slow rays, and the measurements he gives indicate that the velocity of these varies but little from that of the primary rays.

A point of great importance which can easily be shown by this apparatus is that the stage at which luminosity sets in depends upon the current density through the tube, and not merely upon the potential difference. One way of showing this is to lower the temperature of the platinum, keeping all the other conditions the same, and again determine the relation between the current and the potential difference. The effect of lowering the temperature is to reduce the number of corpuscles starting from the kathode, so that with the same potential difference the current density is smaller. If the relation between the current and potential difference is represented by a curve such as Fig. 3, it will be seen at once that the lower curve cannot be deduced from the upper curve by reducing all the ordinates in the same proportion. The critical points on the curves, *i.e.* the place where ionisation by collision begins and where the luminous discharge appears, are at very different potentials: the greater the current density the smaller the potential difference corresponding to these critical points. Thus, to take a case actually observed. When the wire was very hot the discharge was brightly luminous with a potential of 24 volts; on lowering the temperature no luminosity could be detected with a potential difference of 110 volts.

We can also show the effect of current density without altering the temperature of the kathode by placing near the tube an electromagnet so arranged that its lines of magnetic force in the discharge tube are along the line joining the kathode and the anode; the effect of the magnetic field is to make the corpuscles move along the lines of force, and thus without altering the number of corpuscles emitted by the kathode it concentrates their paths and so increases the maximum current density in the tube. When the magnet is on, ionisation by collision and luminosity both occur at a much lower potential difference than when it is off, and it is easy to arrange matters so that, keeping the potential difference constant, the discharge is luminous when the magnet is on and dark when it is off. When the potential difference is too small to produce a bright discharge even when the magnet is on, the current through the tube is often greater when the magnet is on than when it is off. By placing the magnet so that the lines of magnetic force are across the line joining the kathode to the anode we can render the paths of the

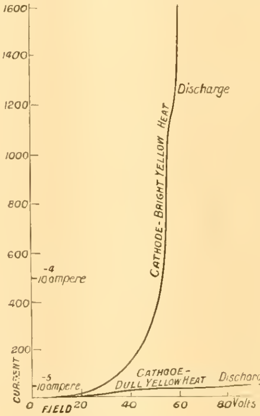

FIG. 3.

corpuscles more diffuse than they would be without the field, so that the maximum current density is less when the magnet is on than when it is off; in this case it requires a larger potential difference to produce a luminous discharge with the magnet on than with it off. Similar effects produced by a magnet on another kind of discharge are described in my "Recent Researches," p. 105.

The potential difference P just where the glow commences, when the pressure is low, sometimes varies so rapidly with the current i as to be roughly inversely proportional to it. The following are some values of i and P for a gas at a constant low pressure as the temperature of the platinum strip was increased; the numbers are in the order of increasing temperature:—

i (in scale divisions)	P (volts)	Pi
6	60	360
8·7	40	348
11·2	30	336
14	25	350

Such a simple relation between P and i is, however, exceptional.

The fact that the potential differences at which ionisation by collision or luminosity begins depend upon the current density, shows that the ionisation or luminosity of an atom need not, and, indeed, cannot entirely, be the result of a *single* collision between a corpuscle and the atom. For if that were the case, then since the energy of the corpuscle depends only upon the electric field, and not upon the current density, the effect of increasing the current density would merely be to increase in the same proportion the number of luminous atoms, while, as a matter of fact, if the potential difference is kept constant and the current increased by raising the temperature of the platinum strip the increase in the luminosity is greater out of all proportion than the increase in the strength of the current.

The result, however, is easily explained if we look at the question from the following point of view. Suppose that for ionisation or luminosity to take place the internal energy of the atom must increase by certain amounts, say E_1, E_2 respectively. Then, if the energy possessed by the corpuscle were very great, the result of one collision with an atom might be to give to the atom enough energy to ionise it or make it luminous, or both. But even if the corpuscle were less energetic, and did not in one collision give enough internal energy to the atom to ionise it, it would communicate some energy to it, and if the atom had any power of storing up energy this would form a contribution towards the critical amount of energy required by the atom before it is ionised. The atom, after having had this energy communicated to it, would, so long as it retained any of it, not require so much energy to ionise it as before. The atom, too, might acquire energy, not merely by corpuscles striking against itself, but also by the collision of corpuscles with neighbouring atoms; such collisions generate soft Röntgen rays, the energy of which might be absorbed by the atom under consideration and help to raise its energy to the critical point; the energy in the Röntgen rays might by itself raise the internal energy of the atom to this value, or else raise it so nearly to this value that the collision with a corpuscle would give it enough energy to carry it past the critical stage. The rate at which the energy, due to collisions of corpuscles with itself or with neighbouring atoms, comes to an atom will be proportional to the rate at which energy is being communicated to the gas, *i.e.* to Fi, where F is the electric force and i the current density, and thus for a constant electric force would be proportional to the current density. The atom will radiate away some of its internal energy; if the rate of this radiation is proportional to the amount of energy, E, possessed by the atom, say equal to βE, then if q is the rate at which energy is being communicated to the atom, we have

$$dE/dt = q - \beta E,$$

so if E vanishes with t,

$$E = q/\beta\,(1 - e^{-\beta t}).$$

Thus q/β is the limit to the energy acquired by the atom, and this is proportional to q, while q is proportional to Fi, so that the atom will acquire the critical amount of energy or not according as Fi is greater or less than a certain value.

Application of these Results to Spectroscopy.—We have seen that the passage from the dark to the luminous discharge occurs with great abruptness, an increase of the potential difference by 1/100 of a volt being sufficient in certain circumstances to convert a discharge in which no luminosity at all could be detected to one where it was quite bright. This suggests that the luminosity sets in when the internal energy of the atom, or rather of that part of it which gives rise to the particular kind of light present in the luminous discharge, attains a perfectly definite value. This way of regarding the origin of the luminosity affords a very simple explanation of the variation of the spectrum with the kind of discharge and of the effect of introducing capacity or self-induction into the circuit containing the discharge tube. Let us consider the rise in energy of a vibrating system inside the atom; let E be the energy at the time t, α the rate at which it is absorbing the work done in the discharge tube; the energy may be supplied to it from the Röntgen radiation in the tube or from the corpuscles which come into collision with the atom, α will be proportional to the rate at which the electric field producing the discharge is doing work in the neighbourhood of the atom we are considering; it will thus be proportional to the product of the electric force and the flux of corpuscles in this neighbourhood. Let us suppose that the system radiates energy at a rate proportional to E, say equal to βE, then we have

$$dE/dt = \alpha - \beta E,$$

or

$$E = \alpha/\beta\,(1 - e^{-\beta t})$$

if $E = 0$ when $t = 0$.

Consider two different systems, A and B, in the same atom; let E_1, α_1, β_1; E_2 α_2, β_2 be the values of E, α, β for the systems A and B respectively.

$$E_1 = \alpha_1/\beta_1\,(1 - e^{-\beta_1 t}),$$
$$E_2 = \alpha_2/\beta_2\,(1 - e^{-\beta_2 t}).$$

Now suppose that the system A is one that does not absorb much, but also does not radiate much, while B absorbs a great deal more than A, but radiates still

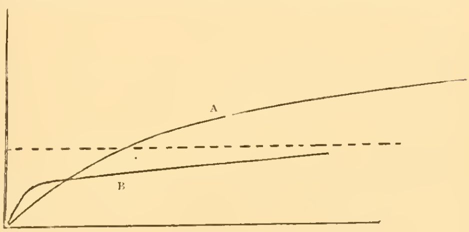

Fig. 4.

more in proportion, so that $\alpha_2 > \alpha_1$ but $\alpha_1/\beta_1 > \alpha_2/\beta_2$, then ultimately E_1 is greater than E_2, but at first E_2 is greater than E_1. The curves A and B, Fig. 4, represent the variations of E_1 and E_2 with the time.

Suppose, now, that systems A and B become luminous when the internal energy is equal to W. It is not necessary to assume that the critical amount of energy is the same for the two systems; the assumption is only made to simplify the diagram; it will be seen that the argument will apply if the critical amounts of energy are different in the two cases.

Now consider, first, the case when the rate at which work is being done in the tube is so small that though α_1/β_1 is greater than W, α_2/β_2 is less than W, the case represented in Fig. 4; here system A acquires the amount of energy necessary to make it luminous, while system B does not; thus in this case the spectrum of the gas would show the lines corresponding to A, but not those of B. Suppose, now, we increase the rate at which work is done in the tube, so that both α_2/β_2 and α_1/β_1 are greater than W, the case represented in Fig. 5.

Here the system B attains the critical amount of energy, and it reaches this value before A does so, so that in this case the lines of B will be visible. Let us now consider the lines in the spectrum corresponding to the system A; these will be visible if the energy in the system reaches the critical value. The conditions in this case are in some respects more unfavourable for the supply of energy to

this system than they were in the previous one. For in the first case the system B got into the condition in which it radiated as much energy as it received, and thus did not absorb any of the energy; in the second case, however, B became luminous before its radiation was equal to the absorption; it is thus taking in more energy than it gives out, and this may result in a diminution in the rate of supply of energy to A. It would be so, for example, to a marked extent if the conditions were such that A received a considerable portion of its supply of energy from B; this diminution in the supply might be great enough to prevent the internal energy in B reaching the critical value. Thus the effect of the increase on the rate of supply of the electrical energy might be to weaken, or even obliterate, the lines of A, and while with the smaller rate we had the lines of A and not those of B, with the larger rate we might have the lines of B and not those of A; thus an increase in the rate at which the electric field is doing work such as would be produced by increasing the current through the discharge tube might result in an entire change of the spectrum. We should expect that it would only be in exceptional cases that the lines of A would be obliterated under the conditions holding in case 2, but in all cases the increase in the brilliancy of the lines of B would be large compared with the increase of those in A.

We see from the equations giving E_1 and E_2 that until the supply of energy has lasted for a time comparable with $1/\beta_2$, E_2 is large compared with E_1; thus for electrical discharges which last for an exceedingly short time we

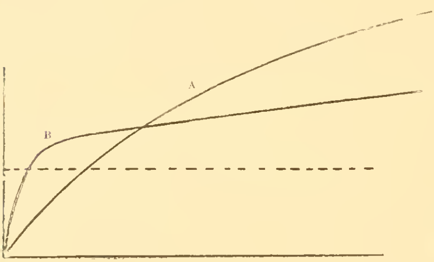

FIG. 5

might easily have the lines of B visible and not those of A.

In a discharge tube conveying an electrical current the amount of work per unit volume of the gas done by the electrical forces per unit time varies very largely from one point of the tube to another; if the cross section of the discharge is the same at all parts of the tube, so that the current density is uniform, the rate at which the electrical forces do work will be proportional to the electric force; as this is much greater near the kathode than at other parts of the tube, we should expect the lines of systems of the type B to preponderate near the kathode, and to be absent or much feebler in other parts of the tube. If the tube were of the type frequently used for spectroscopic purposes with a capillary portion in the middle, then since the current density is much greater in this portion than in any other, the rate of work per unit volume of the gas will be much greater in the capillary portions than in the wide parts of the tube, and we should therefore expect the lines of systems of the type B to be much more prominent in the capillary part than in the wide part.

Effect of Self-induction and Capacity.—Suppose that we have a tube of uniform bore arranged as in Fig. 6, the terminal of the tube being connected with the plates of a condenser of capacity C, and that there is a coil the coefficient of self-induction of which is L placed in series with the tube; then if the discharge through the coil begins when the potential difference between the plates of the condenser is V_0, the potential difference between the plates after a time t will be

$$V_0 \cos pt,$$

and the current through the tube

$$CV_0 p \sin pt,$$

where $p = 1/\sqrt{LC}$.

Thus the maximum value of the product of the current and the potential difference, *i.e.* rate at which the electric forces are doing work in the tube, is $CV_0^2 p$ or $V_0^2\sqrt{C/L}$, and is thus proportional to the square root of the capacity and inversely proportional to the square root of the self-induction. Thus increasing the capacity increases the maximum rate of work, and therefore increases the brilliancy of the lines corresponding to systems of the type B relatively to those of type A, while inserting self-induction in the circuit increases the brilliancy of those of type A as compared with those of type B. If we suppose that the "blue" spectrum of argon corresponds to a system of type B, the red to a system of type A, we have an explanation of the changes in the spectrum of this gas, for by inserting capacity in the circuit we can change from the red to the blue spectrum, while having got the blue we can get back to the red by inserting self-induction. I have here a little model which is intended to illustrate the way in which the red and blue spectra of argon originate. It is based on the fact that when we send a current of electricity through a circuit the current

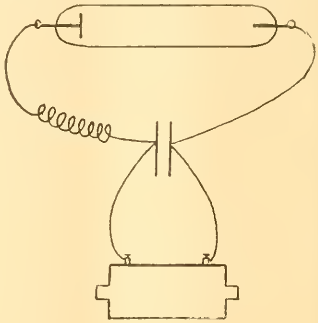

FIG. 6.

does not rise to its steady value instantaneously, but, starting from zero, increases with the time in exactly the same way as we have supposed the intrinsic energy in the atom, *i.e.* the way represented by the curve in Fig. 4. The quantity in the electrical case corresponding to the radiation β is the resistance of the circuit divided by the self-induction, while the quantity α is inversely proportional to the self-induction. Thus a circuit with large self-induction and small resistance is analogous to the system A, while one with small self-induction and large resistance is analogous to a system of type B. Now my model of the argon atom consists of two circuits, C and D, placed in parallel. C has large self-induction and small resistance, D has little self-induction but large resistance. An electric lamp is placed in each circuit. If I supply energy in one way, *i.e.* by continuous current, to the system, the red lamp in C lights up, the blue lamp in D is dark, while if fed by an alternating current the blue lamp shines and the red is dark. It would be interesting to see whether as we gradually diminish the self-induction we get the whole of the lines in the blue spectrum at once, or whether the lines of this spectrum enter in groups one after the other. I have tried somewhat similar experiments with the hot lime kathode to see in a mixture of gases, mercury vapour and air, which spectrum first appeared as the rate of doing work in the gas was gradually increased. The great difficulty in this determination is that when once

the luminosity begins there is such a rapid increase in the ionisation that the current through the gas and the rate of doing work increase in an exceedingly short time through a wide range of values, and thus a gradual increase in the rate of work is exceedingly difficult to obtain. On several occasions, however, I was convinced that on gradually increasing the rate of work the mercury lines were the first to appear, and were the last to disappear when the rate of work was reduced from a high value, at which both the nitrogen and mercury spectra were bright, down to a point where the discharge ceased to be luminous.

The preceding considerations have also an important application to the difference between the arc and spark spectra. In the continuous arc discharge, although the average rate of work is much higher than in the spark, the maximum rate is very much less; in the spark discharge we have an exceedingly intense current density lasting for a very short time, and while the spark is passing we have a very much greater rate of work than in the arc. Hence the state of things in the spark will be analogous to that represented in Fig. 5, and the lines corresponding to systems of the type B will be enhanced relatively to those of type A; we conclude, then, that the arc lines correspond to systems of the type A, the spark lines to those of type B.

The work done in the discharge tube is probably ultimately converted for the most part into heat, so that the rate at which work is being done at any part of the tube is approximately proportional to the rate at which heat is being produced in the tube. I do not, however, regard temperature, *i.e.* the energy due to the translation of the atoms as a whole, as having any direct connection with the production of spectra. The work done by the electric field on the corpuscles is, since the corpuscles can easily penetrate the atoms of the gas, first converted into internal atomic energy; this energy may ultimately be for the most part transformed into the energy of translation of the molecules of the gas, and so appear as temperature, but it by no means follows that if we heat the molecules of the gas by non-electrical means to the temperature to which even a few of its molecules are raised by the electric discharge we shall get a luminous spectrum. The production of the spectrum depends upon the internal energy of the atom; when we use the electric discharge all the work done by the corpuscles goes at first into the form of internal atomic energy, while if we supply the same amount of energy to the gas by thermal, as distinguished from electrical, means, the energy will go first into increasing the energy of translation of the atom, and very little of it will ever get inside the atom. It is probable, however, that some of the energy of translation will get converted into internal energy, and that temperature is one way of giving internal energy to the atom, and so producing luminosity; from our point of view, however, it is a very extravagant method, as the fraction of the energy spent in heating the gas which goes to produce luminosity is small.

The coefficient of absorption α of the systems will depend upon the way in which the internal energy is given to the atom as well as upon the rate at which the electric field is doing work in the neighbourhood of the atom. Thus, for example, if the internal work is given by means of rapidly moving corpuscles, the coefficient of absorption will depend upon the velocity of the corpuscle, for we can easily show that when a corpuscle passes at a fixed distance from a system of corpuscles having a definite period of vibration there is one velocity of the corpuscle, depending on this period, fast if the period is short, slow if it is long, for which the energy given by the corpuscle to the system is a maximum. Thus the relation between the amounts of energy absorbed by two systems from the corpuscles depends upon the velocity of the corpuscles. The velocity of the corpuscles in a discharge tube depends upon the pressure of the gas, so that even though the rate at which the electrical forces are doing work may be the same at two different pressures, the relative intensities of the lines of two systems A and B may be different.

Again, we might expect that the coefficient of the rate of absorption of energy would be different according as the energy is given to the atom by means of the large systems which form the positive ions or by means of small corpuscles, and that the relative brightness of lines might be different in the two cases. In the Kanal-strahlen we have positive ions moving through a gas and producing luminosity, and the spectrum of this luminosity possesses interesting peculiarities differentiating it from the spectrum of other parts of the tube. Perhaps the most striking difference, however, is when the positive ions strike against a salt like lithium chloride; they make the red lithium line appear with great brilliancy, while if corpuscles strike against the chloride the red line is not visible. It is remarkable that the spectrum of the metal is produced much more readily by the positive ions when they strike against a salt of the metal than when they strike against the metal itself; this is shown in a striking way if we take the liquid alloy of sodium and potassium and direct a stream of Kanal-strahlen upon it; the clean parts of the alloy appear quite dark, but the specks of oxide scattered over its surface shine with a bright yellow light, giving the sodium spectrum.

When the internal energy of the atom is increased by means of light, as in Prof. Wood's beautiful experiments on the fluorescence of sodium vapour, the coefficient of absorption of a system will depend upon the relations between the periods of that system and the period of the incident light vibrations; thus, as Prof. Wood found to be the case, the numerous lines in the spectrum given out by the vapour alter greatly in character and wave-length when the period of the incident light is changed.

The same principles which explain the variation in the intensities of the spectra given out by two different systems in the same atom can be applied to explain the variations in the intensities of the spectra of two gases, A and B, when these are mixed together. We know that under some conditions the lines of only one constituent of the mixture appear, while under others we get the lines of both the gases. Let us suppose that the lines of A appear with a lower rate of work of the electric forces than those of B, and that we send a constant current through the discharge tube, we can calculate what the electric force must be to produce from the molecules of A alone the number of ions required to carry this current; having found the electric force on this supposition, we can, knowing the current, find the rate at which the electric forces would be doing work in the tube; if this rate of work is less than that required to make B luminous, the current will be carried by the ions of A alone, and the spectrum of B will not be developed; if the rate of work on this supposition is greater than that required to make B luminous, the spectrum of B will appear, and it must take a share in carrying the current. Let us suppose that we have so much of A present that the rate of work is not sufficient to develop the spectrum of B, and consider what will happen as the proportion of A is diminished. In order to supply the number of ions required to carry the given current from the smaller number of molecules of A, the electric force, and therefore the rate of work in the tube, must, on the supposition that the current is wholly carried by A, increase, and if we continually diminish the amount of A present the rate of work will at last reach a value sufficient to make B luminous with the given current. This stage will give the smallest quantity of A which can for the given current wholly swamp the spectrum of B. The rate of work done in the tube will depend on the current going through it and also on the pressure of the gases, so that both these quantities will influence the proportion of the gas B required to make its spectrum visible.

MICROSCOPIC AQUATIC PLANTS AND THEIR PLACE IN NATURE.[1]

EVERY piece of water, besides containing large plants and animals which are readily visible to the naked eye, harbours a more or less considerable number of minute forms, which pervade all the layers of the water in varying amount, and collectively constitute the plankton or pelagic life. The most important difference between the

[1] Abstract of a lecture on "The Microscopic Plants of our Waters," delivered before the London Institution on February 1 by Dr. F. E. Fritsch.

plankton and the remaining flora and fauna of our waters lies in the fact that all the organisms which compose it are free-floating during the greater part of their life. Practically all the pelagic plants belong to the group of the algæ, and their minute size, of course, suits them well to a floating existence. A certain number of them are motile (*e.g.* Volvox, Gonium, Pandorina, &c.), and these are able actively to maintain themselves in their position in the water; but the large majority are non-motile, and all these forms are slightly heavier than water, and consequently tend to sink; they develop diverse mechanisms, by means of which their power of flotation is increased. The most important of these are:—assumption of a flat plate-like shape (Pediastrum, Merismopedia, many Desmids); development of numerous delicate processes from the body of the plant (Stephanodiscus, Richteriella); arrangement of the individuals of a colony in a more or less stellate manner (Asterionella, some Tabellarias); assumption of a delicate acicular shape (Synedra); formation of fat in the cell (many Diatoms and Cyanophyceæ), and so on.

In spite of these adaptations, however, most of the non-motile organisms of the plankton sink to the bottom of the containing vessel in the space of a few minutes after they have been collected. How is it that this does not happen in nature? It has been suggested that the continuous currents in the water, due to the wind and other causes, help to buoy up the organisms of the plankton; but it is of course also possible that in collecting such delicate forms they are damaged in some way or other so as to deprive them of that power of floating which suits them so well to their natural habitat. An interesting point connected with the development of the diverse floating mechanisms is that in some plants they have been found to be far more strongly developed in the summer than in the winter forms; this is, undoubtedly, in some way connected with the lower specific gravity of the water in summer, although the exact relation is not yet quite evident.

If the plankton of any piece of water is examined from week to week or month to month, we find not only astonishing variations in the quantity of organisms present, but also very marked differences in the specific constitution of the pelagic life. The quantity of the plankton is generally very much less in the winter than in the summer months, and the organisms composing it are quite different in the two seasons. Thus in the Thames there are four well marked annual phases, each characterised by its own peculiar plankton. This periodicity exhibited by the pelagic life stands in close relation to the external seasonal changes; some of the forms prefer cold, others warm water, and consequently they flourish in those seasons which are most to their liking. Some plants are particularly sensitive, and consequently only put in an appearance for a very short space of time each year. During their period of absence from the plankton these organisms persist as resting spores in the mud at the bottom of the piece of water; when favourable conditions return the spores germinate, giving rise to a new generation of pelagic organisms, which by their prolific division are able to dominate completely a piece of water in a few days' time.

The pelagic plants form the food of the animal plankton; these, again, are devoured by their larger brethren, which are the main source of nutrition for the smaller fishes. The larger fish are mostly carnivorous, feeding on smaller individuals of their kind. The organic matter of the pelagic plants thus gradually travels from one organism to another until it comes to form part of the body of the large aquatic animals; it passes through a series of incarnations before being returned to the water in the form of excrements or products of decay of dead animal and vegetable bodies. This organic matter is built up by the pelagic plants from simple inorganic salts and from carbon dioxide dissolved in the water, and these latter substances are thus changed into a form which makes them available to the aquatic fauna. All the organisms of the latter, as, indeed, all the animals of the world, are ultimately herbivorous. Without some kind of plant growth a piece of water must remain a lifeless, dead mass, unpopulated, and a thing apart from the living world around it. The presence of vegetation immediately transforms it into a throbbing universe, full of energetic life, exhibiting complex inter-relationships, and connects it with the remaining parts of our universe. The most important element of the vegetation from this point of view, however, is the phytoplankton, and a piece of water with plenty of pelagic plants is sure to form a good breeding-place for fish and other aquatic animals.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—The report of the committee of the school of geography for 1905 shows that the school now holds a strong position in the University, and is doing valuable work in encouraging the study of geography and surveying, and in providing special courses of geographical lectures suited to the requirements of the different final honour schools. Both the lectures and practical instruction were well attended throughout the year, although there were only a few candidates for the diploma. This year, in addition to the ordinary work during term, a special course lasting three weeks, specially suited to those who are engaged in teaching, is being arranged for August. The instruction will be both practical and theoretical, and there ought to be no lack of support for so useful an innovation.

Cambridge.—The forestry committee having been commissioned to submit a scheme of study and examination for the diploma in forestry, recommends that the Senate approve the following:—Candidates, before receiving the diploma in forestry, shall be required to produce evidence that they have (1) passed (or obtained exemption from) the Previous examination, together with the additional subjects; (2) satisfied the examiners in physics, chemistry, geology, and botany, either in part i. of the examination for the diploma in agriculture, or in that examination in combination with the Natural Sciences Tripos, part i., or in some other examination or examinations approved by the committee; (3) diligently attended courses of instruction in forest botany, in entomology, in forestry, in forest mensuration, surveying, and engineering, and such other courses in related subjects as may from time to time be approved by the committee; (4) attended for a time equivalent to one academical year courses of instruction in practical forestry approved by the committee; (5) obtained a certificate of proficiency in practical forestry approved by the committee; (6) passed the examination for the diploma; (7) been admitted to a degree in the University.

The general board of studies has approved for the degree of Doctor in Science Mr. G. H. F. Nuttall, Christ's College.

The general board of studies also recommends that it be authorised to appoint, subject to confirmation by the special board for medicine, Mr. G. H. F. Nuttall to be reader in hygiene in connection with the special board for medicine; that the university lectureship in bacteriology and preventive medicine terminate on his appointment as reader; and that the readership terminate with the tenure of office of Mr. Nuttall.

Dr. W. A. Thornton has been appointed to the newly-created professorship of electrical engineering at Armstrong College, Newcastle.

According to a message from Wolfville, Nova Scotia, Mr. Carnegie has promised to the Acadia University 6000*l.* for a new science building as soon as 20,000*l.* has been raised for a forward movement now in progress. Of this sum nearly half is already in hand, and the rest is definitely promised.

The council and principal of the Bedford College for Women will hold the usual reception at the college on Commemoration Day, May 9, after the presentations for degrees at the University of London. The Pfeiffer entrance scholarship in science, tenable for three years, and of the annual value of 48*l.*, will be offered for competition in June next.

At the annual dinner of the students of the Camborne Mining School, held in Camborne on March 10, the prin-

cipal, Mr. J. J. Beringer, in reviewing the growth of the school for the past ten years, made some remarks upon the recent report of the departmental committee on the Royal College of Science. He pointed out that while the fellows of the faculty of mining and metallurgy may be only capable of being produced and fully nourished to maturity in the new institution, yet the general practitioners would still find their way to Camborne for their training. The chairman of the school committee, Mr. C. V. Thomas, remarked that though encouragement was given by the Government and the County Council, sufficient material assistance had always been wanting, and plans for extensions were crippled for want of funds.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 7, 1905.—"A Biometrical Study of Conjugation in Paramæcium." By Dr. Raymond **Pearl**. Communicated by Prof. Karl Pearson, F.R.S.

The purpose of this investigation was to determine whether any sensible differentiation exists between the conjugating and non-conjugating members of a population of the common ciliate infusorian *Paramaecium caudatum*, and to what degree structurally similar individuals tend to pair together in conjugation. The characters principally studied were length and greatest breadth of the body, and the shape of the organism as measured by the length-breadth index. The material used covered a considerable range of cultural conditions. It was found that there is a very considerable differentiation between conjugant and non-conjugant individuals. In respect to the absolute size characters (length and breadth of body), the differences between the means for the two groups of individuals amounted to from 10 per cent. to 20 per cent. of the mean size of the larger (non-conjugant) individuals. Not only are conjugants absolutely smaller than non-conjugants, but they are also sensibly differentiated in shape. Further, they are much less variable, and less highly correlated. There is a strongly marked tendency for like to pair with like in the conjugation of Paramæcium. The coefficients of correlation measuring homogamy in conjugation, are relatively very high, both for direct and cross assortative pairing, in all the characters examined. By an experimental study of random pairings it was shown that this homogamy in conjugation is due to a real assorting and pairing of like with like, and not a spurious effect of local differentiation in the culture. Further, by comparing records obtained from recently united pairs of conjugants with similar records from pairs about to separate, it was shown that the results cannot be due to any process of equalisation in size during the process of conjugation itself. The probable manner in which the homogamic pairing is brought about is discussed, and it is shown that the results are easily explicable on the basis of known facts regarding the behaviour of the organism. It is pointed out that the demonstration of the existence of a relatively fixed "conjugant type" has a direct bearing on current views as to the theoretical significance of protozoan methods of reproduction. The importance of getting positive evidence that a sensible degree of homogamy actually exists among organisms living under natural conditions has been many times emphasised by writers on evolution. The present work brings forward such evidence for a single organism standing low in the scale of organisation.

January 18.—"A Case of Regeneration in Polychæte Worms." By Arnold T. **Watson**. Communicated by Prof. C. S. Sherrington, F.R.S.

January 25.—"On the Overstraining of Iron by Tension and Compression." By Dr. James **Muir**. Communicated by Prof. A. Gray, F.R.S.

The behaviour of mild steel under compression is investigated. Compression stress-strain curves are usually shown very much rounded at the yield-point. In this paper a specimen of steel is shown to have obeyed Hooke's law until abrupt permanent shortening occurred at the stress of 21½ tons per square inch. At this stress the reading on a Ewing "compression extensometer" altered from 241 to 2900 without increase of load. This permanent shortening at the compression yield-point was found to be practically equal to the extension at the tension yield-point of the same material. A second compression test made on the same specimen, after recovery from the compressional overstrain, showed that the compression yield-point had been raised by a step of 4 tons per square inch. This was approximately the step by which the tension yield-point of the material could be raised by tensile overstrain.

Experiments were further made to investigate the behaviour under compression of steel which had previously been subjected to tensile overstrain. The experiments seem to indicate that there are two distinct causes contributing to the phenomenon of hardening by tensile overstrain:—(1) the overstraining itself—the actual stretching of the material—seems to harden the material equally as regards both resistance to tension and to compression; while (2) the process of recovery from tensile overstrain, which seems to bring into existence an internal stress, raises the tension yield-point by a definite step above the overstraining stress, but seems to lower the compression yield-point by approximately an equal amount below the overstraining stress. For example, a specimen subjected to a series of tension tests in which the loading is carried just beyond the yield-point (recovery from overstrain being effected between each test) might exhibit yield-points at 20, 25, 30, 35, and 40 tons per square inch. The corresponding compression yield-points should probably occur at about 20, 15, 20, 25, and 30 tons per square inch. This conjecture can scarcely be said to have been fully established, further research being necessary; but it is shown that steel may be hardened by tensile overstrain to resist higher stresses both in tension and in compression, although material so hardened always withstands a greater stress in tension than in compression.

February 8.—"Polarisation in Secondary Röntgen Radiation." By Dr. C. G. **Barkla**. Communicated by Prof. J. J. Thomson, F.R.S.

In a previous paper the author gave an account of experiments which demonstrated the partial polarisation of a beam of X-rays proceeding from the anti-kathode of an X-ray focus tube. The secondary radiation from substances of low atomic weight placed in the primary beam, however, varied in intensity in the two principal directions by not more than about 20 per cent.

The experiments described in this paper were made on the secondary radiation proceeding from a substance of low atomic weight, for, according to the theory given, the radiation proceeding in a direction perpendicular to that of propagation of the primary should be almost completely polarised.

The method was similar to that used in previous experiments, the intensity of tertiary radiation from a light substance placed in the secondary beam being studied by means of electroscopes, shielded from the direct primary and secondary radiations.

The principal experimental difficulties were due to the weakness of the tertiary beams.

Carbon was chosen as the radiating substance because the energy of secondary radiation from substances of low atomic weight had been found to be proportional merely to the quantity of matter passed through by a primary of given intensity, and as absorption diminishes with the atomic weight, the lower the atomic weight the greater is the energy of secondary radiation proceeding from thick plates exposed to a given primary.

A large mass of carbon was placed in the primary beam, and the horizontal secondary beam proceeding from this in a direction perpendicular to that of propagation of the primary was studied. In it was placed a second mass of carbon, and two electroscopes were situated to receive tertiary rays proceeding in horizontal and vertical directions. As the X-ray tube was turned round the axis of the secondary beam, the intensities of tertiary radiation in the two directions changed, one increasing to a maximum while the other decreased to a minimum.

It was found that the horizontal tertiary reached a maximum and the vertical a minimum when the primary beam was horizontal, and that the conditions were reversed when the primary was turned through a right-angle.

This result was anticipated by the theory previously given, and may be explained by considering the electrons in the radiating substance to be accelerated in the direction of electric displacement in the pulses passing over them.

The intensities in the two principal directions were approximately in the ratio 3 : 1. Considering the obliquity of primary, secondary, and tertiary rays in the beams experimented upon, this result indicates fairly complete polarisation in a narrow pencil of secondary radiation proceeding from the substance in a direction perpendicular to that of propagation of the primary.

When iron was used as the radiator in the secondary beam, though the rates of deflection of the electroscopes were of the same order of magnitude as before, there was no appreciable variation as the direction of the primary beam was changed.

This result was what previous experiments on iron led one to expect, and was the most conclusive proof of the interpretation of the results obtained with carbon. The independence of motion of the electrons disappears in the heavier atoms, and each is subject to considerable forces not directly due to the primary pulse (in this case the secondary pulse) and not in the direction of electric displacement in this pulse. Hence the variation in intensity of the tertiary in different directions becomes inappreciable, while the pulse thickness in the tertiary beam becomes greater than in the secondary, and is consequently more readily absorbed.

Geological Society, February 16.—Annual General meeting. Dr. J. E. Marr, F.R.S., president, in the chair.—Influence of the geological structure of English Lakeland upon its present features. Anniversary address: **President.** After an account of the light thrown upon the structure of Lakeland by the writings of other geologists, the president considered his subject under the following heads:—Events prior to the uplift which produced the dome; production of the dome; initiation of the drainage-lines; effects of the three types of rocks upon the scenery; modification of old drainage-lines; depression of the outskirts; effects of meteorological conditions, (1) general, (2) the Glacial period. Of the events prior to the dome-shaped uplift, he laid greatest stress upon the movements of Devonian times, which had caused the Lower Palæozoic rocks to be affected by fractures forming a roughly rhomboidal network, the fissures being marked by belts of broken rock along their courses. He accepted Hopkins's view of the formation of a dome comparable in shape to a "caddy-spoon" with the short handle to the east. He gave further reasons in support of the view that the uplift of the dome and the final movements of the Pennine Chain were of Tertiary date. After commenting on the theory that rocks of New Red Sandstone age extended over the district, he discussed the nature of the radial drainage impressed upon these newer rocks during the uplift of the dome, and the removal of these rocks in the district itself by denudation, producing a superimposed drainage on the Lower Palæozoic rocks. The changes which took place in the valleys as the result of the imposition of the rivers upon the ancient rocks were then discussed, and it was maintained that diversion of the river-courses had largely taken place owing to the easier erosion along the shatter-belts. When discussing the effects of meteorological conditions he commented on hill-outlines, where the upper parts of hill-slopes presented a convex outline towards west and south, and a concave curve towards east and north. This he attempted to explain as due to the more profuse growth of vegetation on the slopes facing west and south.

February 21.—Sir Archibald Geikie, Sec.R.S., president, in the chair.—The constitution of the interior of the earth, as revealed by earthquakes: R. D. **Oldham.** This paper sets forth the information to be obtained from the records of distant earthquakes. The record of a great earthquake exhibits three phases, of which the third represents wave-motion travelling along the surface of the earth, and can give no information regarding the interior. The other two phases form the preliminary tremors, and represent the emergence of two forms of wave-motion propagated through the earth. Up to a distance of 120° of arc from the origin, these waves are propagated at a rate which increases with the depth of the wave-path, and reaches an average of more than 10 km. sec. for the first-phase, and more than 6 km. sec. for the second-phase waves. The increase may be attributed to the effect of increased pressure and temperature. Beyond this limit the first-phase waves show a reduction in the mean rate of transmission, while the second-phase waves are found, not where they would be expected, but at about 11′ later. Two interpretations are given. Either alternative leads to the conclusion that, after the outermost crust of the earth is passed, there is no indication of any rapid change of physical and chemical properties until a depth of about six-tenths of the radius is reached.—The Tarannon series of Tarannon: Dr. Ethel M. R. **Wood.** The Tarannon strata are well developed in the Llanbrynmair-Tarannon district, and the present paper gives the results of a detailed survey of the entire Tarannon series as there exhibited. Lists of the contained graptolites are given, and the species are paralleled with those from the corresponding beds of the south of Scotland, the Lake District, North Wales, central Wales, and Sweden, demonstrating the similarity of the graptolitic succession in all these districts. The Tarannon series in this district has a maximum thickness of 3500 feet, but thins somewhat as it is traced north-westward. It rests conformably on Llandovery rocks below, and passes up without a break into Wenlock beds above. This rock-series is stratigraphically continuous from base to summit. The strata of the overlying Wenlock series present all the characters of the Denbigh Grits and Flags of North Wales. The Llandovery series, which underlies the Tarannon series, has, at present, been recognised only in the western part of the district, namely, in the valley of the Twymyn, and its rocks are brought to the surface by an anticlinal fold. A comparison of the graptolitic lists shows that the Tarannon series, as here defined, corresponds almost exactly with the Gala or Queensberry group of the south of Scotland, includes all the palæontological zones hitherto assigned to the Tarannon, and fills up the whole period intervening between the Llandovery below and the Wenlock above.

Physical Society, February 23.—Prof. J. Perry, F.R.S., president, in the chair.—A note on Talbot's lines: J. **Walker.** The diffraction-pattern of a line of monochromatic light seen in focus, due to a rectangular aperture with its sides parallel to the line, is characterised by dark bands arranged at equal intervals on either side of the geometrical image of the line. The effect of covering half the aperture with a retarding plate is to displace the bands of an odd order towards the covered side by an amount proportional to the retardation introduced, those of an even order remaining fixed. Suppose that the light is white and that its monochromatic constituents have been made by spectral analysis to occupy different angular positions in the field. Owing to the dispersion, the bands of an even order are obliterated; but in the case of those of an odd order the dispersing power of the plate itself produces a dispersion of the bands, and consequently these bands will be seen, provided the plate have a suitable thickness and be so placed that the dispersion of the bands produced by it acts in opposition to the primitive dispersion of the light.—Secondary Röntgen radiation: Dr. C. G. **Barkla.** In previous papers the author has shown that the secondary X-rays from certain gases and light solids subject to Röntgen radiation may be fully explained by considering the corpuscles or electrons constituting the atoms to be accelerated in the direction of electric displacement in each primary Röntgen pulse as it passes through such substances, and that the interaction between the electrons affects only to a slight extent the character of the secondary radiation. Experiments on the absorption of rays proceeding from thick plates of a large number of elements showed that beyond the region of atomic weights in which the character of the secondary radiation is almost independent of the nature of the radiation, the absorbability is a periodic function of the atomic weight of the radiator, and that, so far as these experiments have gone, different periods are represented by curves of similar form. The theory which has been found to explain all the pheno-

mena of secondary radiation from light atoms may be extended to explain these results, if the independence of motion of the electrons is conceived to disappear with an increase in the number of electrons in the atom.—Records of the difference of potential between railway lines when a train passes and at other times, and a suggested method for the observation of earth currents and magnetic variations: C. W. S. **Crawley** and F. B. O. **Hawes.** The experiments described in the paper were made on the London and South-Western main line, between Walton and Weybridge stations. To each rail of the up line a wire was permanently attached, and the other ends of the wires were connected to the terminals of a reflecting galvanometer. The deflections of the galvanometer were recorded on a moving sheet of paper, and curves obtained showing the variation in the current through the galvanometer. The curves showed a concordance in the results from successive trains. The normal current through the galvanometer began to be disturbed about one minute before the passage of a train, and the disturbance lasted about two minutes.

Royal Microscopical Society, February 21.—Dr. Dukinfield H. Scott, F.R.S., president, in the chair.—A method of producing stereo-photomicrographs: W. P. **Dollman.** A number of good stereoscopic prints were exhibited in the room in illustration of the paper.—A simple method of taking stereo-photomicrographs and of mounting the prints without cutting: Mr. **Taverner.** Though this paper was upon the same subject as the previous one, the methods of the authors were different, and Mr. Dollman limits his operations to very low powers, giving amplifications of 9 to 20 diameters only. He uses a stop in front of the objective, and exposes first one side of the lens and then the other as he takes his two stereoscopic pictures. Mr. Taverner uses higher powers, and a peculiar stop at the back of the objective. The authors adopt a similar arrangement for obviating the necessity of cutting the prints.—A second list of rotifers of Natal: Hon. T. **Kirkman.** The author described a remarkable new species, *Copeus triangulatus*.

Anthropological Institute, February 27.—Prof W. Gowland, president, in the chair.—Ancestor worship in Japan: W. G. **Aston.** It was shown that the so-called ancestor worship of the Japanese is in reality a cult of the sun and other nature deities, but as the sun or sun-goddess, by a genealogy which covers a period of about 2,000,000 years and contains many miraculous incidents, is feigned to be the ancestor of the Mikados, the Japanese naturally speak of this cult as ancestor worship. We should not follow their example. The descent of the Japanese nobility from the sun-goddess and other deities of the old Pantheon is to be regarded in the same light. There is a worship of true ancestors in Japan, but it is due to Chinese influence, and is of later origin.—Anthropological notes from Lake Tanganyika: W. A. **Cunnington.** The author dealt with the manners, customs, and arts, &c., of the natives living by the lake. Among the slides exhibited was a series showing the different stages of the manufacture of a pot, the peculiar point being that the bottom of the pot is put in last. Other slides showed examples of weapons, dress, houses, and costumes of the natives.

March 13.—Prof. W. Gowland in the chair.—A collection of Palæolithic implements from the neighbourhood of Southampton: W. **Dale.** The author divided the implements into the following groups:—flakes, plain and trimmed; implements with the butt end purposely left smooth, used for chopping; oval- and almond-shaped implements with a cutting edge all round; pointed implements with both edges equal, and tapering gradually; pointed implements with one curved and one straight edge, adapted for making long cutting strokes; pointed implements in which one side has been left as flat as possible—these occur very sparingly in the Hants gravels.—Materials for a study of tatu in Borneo: R. **Shelford** and Dr. C. **Hose.** The paper contained the observations made by the writers amongst the Kayans, Kenyahs, Bakatans, Kalabits, and Sea-Dayaks of Sarawak. All the information on the subject by previous writers had been analysed and compared, special use being made of Dr. A. Nieuwenhuis's books on Borneo. Kayan tatu, which is still a flourishing art, was described in considerable detail, not only with reference to the tatu designs employed, but also to the elaborate ceremonial accompanying the practice. The Kenyahs and Sea-Dayaks also appear to have borrowed the practice of tatu very largely from the Kayans; but most of the Indonesian tribes have all had at one time or another a distinctive tatu. It is most unfortunate that the practice is rapidly dying out amongst these people. It was not found possible to classify the tatued peoples of Borneo in three main divisions as had been done by Dr. Nieuwenhuis for those of a less extended area.

Linnean Society, March 1.—Prof. W. A. Herdman, F R.S., president, in the chair.—A new type of stem from the Coal-measures: Dr. D. H. **Scott.** The stem is one of the many interesting fossils obtained from the pit at Shore-Littleborough, in Lancashire, opened up for scientific purposes by the generosity of the owner, Mr. W. H. Sutcliffe. The sections were cut by Mr. J. Lomax. The specimen was derived from one of the roof-nodules, which generally represent a peculiar flora, distinct from that of the seam-nodules immediately below. Specimens of the great petioles of the same plant had been discovered a year or two before the stem itself came to light. The fragment was about 15 cm. long, and belonged to a stem of considerable size, the diameter being about $12 \times 6 \cdot 5$ cm. The new stem is referred to the family Medulloseæ, of which it constitutes a unique type. It is placed in a new genus, named Sutcliffia, in honour of Mr. Sutcliffe, of Shore-Littleborough, and the specific name *S. insignis* is proposed for it.—Notes on some species of Nereis in the district of the Thames estuary: Dr. H. C. **Sorby.** In the course of yachting expeditions during successive summers for more than twenty years, Dr. Sorby has observed some remarkable facts connected with the Heteronereis form in two species of Nereis. The rarity of the occurrences should make the record of them acceptable. Notes are given in the paper on five species of Nereis found in the Thames district.

Sociological Society, March 14.—Prof. E. Ray Lankester, F.R.S., in the chair.—Notes on the sociological appeal to biology for suggestion: Prof. J. A. **Thomson.** The sociologist is beginning to recognise the usefulness of analysing out the organic processes which contribute to the result which we call social activity. The same is true of the sociologist's appeal to biology. If the recognition of biological factors operative in social activity is very partial the result is sure to be fallacious. By recognising the operation of biological factors in the life of a societary group the sociologist brings what is distinctively social into greater prominence. There is some danger of an inaccurate "materialism" if we pretend that sociology is merely a higher department of biology. The chief value of the appeal to biology by sociological students is threefold:—(*a*) aiding in analysis; (*b*) showing that various modes of social activity have a biological aspect; (*c*) suggesting from biological experience the discovery of sociological laws.

PARIS.

Academy of Sciences, March 12.—M. H. Poincaré in the chair.—The propagation of a movement round a centre in an elastic, homogeneous, and isotropic medium: J. **Boussinesq.**—The effects of the absorption of tuberculin by the digestive tube in healthy and tuberculous animals: A. **Calmette** and M. **Breton.** The experiments described show that tuberculin, when absorbed by the alimentary canal, is toxic for non-tuberculous animals, the effect being especially marked for young animals. The tuberculin is no better tolerated when the dosage starts from a minimum and is progressively increased. For tuberculous animals a very much smaller dose of tuberculin is poisonous.—The evolution of the Tertiary mammals: the importance of migrations: Charles **Depéret.**—The seventh scientific voyage of the *Princess Alice*: **Prince Albert of Monaco.** General description of the work done in oceanography, zoology, microbiology, and meteorology of the Sargasso Sea, in mid-Atlantic.—Observations of the comet 1906*b*

made with the large equatorial of the Observatory of Bordeaux: E. **Esclangon.** The observations were made on March 6 and 7. The comet had the appearance of a star of 10·5 magnitude, surrounded by a very feeble luminosity.—The electromotive forces of contact between metals and liquids, and an improvement in the ionograph: Charles **Nordmann.** Diagrams are given of the apparatus and of a record of the recording instrument for a period of twelve hours.—The sympathetic vibration of a string giving a low note under the influence of one giving a higher note, and the possible consequences arising from this: Edmond **Bailly.** It has been held up to now that a note cannot produce a sympathetic vibration in a string of lower pitch than itself. The author describes an experiment leading to a contrary conclusion.—The action of hot sulphuric acid on salts of platinum and iridium in the presence of sulphate of ammonium: Marcel **Delépine.** Both these metals are dissolved by boiling sulphuric acid in very appreciable quantities. Complex acids appear to be formed in which the sulphuric acid is not precipitable by barium chloride.—The action of peroxide of nitrogen on ammonia and some ammoniacal salts: MM. **Besson** and **Rosset.** When liquid ammonia at −90° C. is added to solid nitrogen peroxide at the same temperature there is a violent explosion. The reaction can be moderated by working with ammonia gas at −20° C.; the products are nitrogen, nitric oxide, and ammonium nitrate.—The action of silicon chloride upon cobalt: Em. **Vigouroux.** At a high temperature silicon chloride is reduced by cobalt, a volatile metallic chloride being formed and a cobaltosilicon remaining behind. The amount of silicon in this latter compound tends to the silicide Co_2Si as a limit.—The dilactide of lævorotatory lactic acid: E. **Jungfleisch** and M. **Godchot.**—A method of determination of the foreign materials contained in cocoa and chocolate: F. **Bordas** and M. **Touplain.** The substance is treated with carbon tetrachloride mixed with varying proportions of benzene, so as to get a range of density between 1·6 and 1·346. A separation of the materials of different densities is readily effected.—Polyvalent antioxydase serum: C. **Gessar.**—Contribution to the systematic anatomy of some kinds of ferns: Ferdinand **Pelourde.**—Nuclear fertilisation in the Mucorineæ: M. **Dangeard.**—*Hylochoerus Meinertzhageni*: Maurice **de Rothschild** and Henri **Neuville.**—The structure of the cæcum or filiform appendices of the middle intestine of *Phyllium crurifolium*: L. **Bordas.**—The comparative anatomy of the Sipunculidæ: Marcel A. **Hérubel.**—The evolution of the supposed coccidia of cephalopods: Th. **Moroff.**—A new disease of the trout: L. **Léger.**—The analysis of tubercle bacilli: G. **Baudran.** Separate analyses were made of dead and living bacilli. The former gave lecithin, cholesterin, and fat, cellulose, nuclein, and albumenoid materials. The living bacilli gave, in addition, an anaëroxydase and an alkaloid.—The reaction of the blood a function of nutrition: Jean **Gautrelet.** There is an absolute parallelism between the apparent alkalinity of the blood and the activity of the organic exchanges as measured by the amount of hæmoglobin.—The Pleistocene glaciers in the valleys of Andorre: Marcel **Chevalier.**—The volcanoes of the Livradois and Comté, Puy-de-Dôme: Ph. **Glangeaud.**—The tectonic of the Ivrée and Strona zones: Émile **Argand.**—The diatom-bearing sediments of the region of Lake Tchad: Paul **Petit** and H. **Courtet.**

DIARY OF SOCIETIES.

THURSDAY, MARCH 22.

ROYAL SOCIETY, at 4.30.—*Bakerian Lecture*: Recent Advances in Seismology; Prof. J. Milne, F.R.S.—On Methods whereby the Radiation of Electric Waves may be mainly confined to Certain Directions, and whereby the Receptivity of a Receiver may be restricted to Electric Waves emanating from Certain Directions: Chevalier G. Marconi.—A Note on the Theory of Directive Antennæ or Unsymmetrical Hertzian Oscillators: Prof J. A. Fleming, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Electrical Equipment of the Aberdare Collieries of the Powell Duffryn Co.: C. P. Sparks.—Electric Winding considered Practically and Commercially: W. C. Mountain.

ROYAL INSTITUTION, at 5.—Internal Combustion Engines: Prof. B. Hopkinson.

FRIDAY, MARCH 23.

ROYAL INSTITUTION, at 9.—Imperial Defence: Lord Roberts.

PHYSICAL SOCIETY (University College), at 5.—On Unilateral Electric Conductivity over Damp Surfaces: Prof. F. T. Trouton, F.R.S.—The Construction and Use of Oscillation Valves for Rectifying High Frequency Electric Currents: Prof. J. A. Fleming, F.R.S.—On the Use of the Cymometer for the Determination of Resonance Curves: G. B. Dyke.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Waves: F. K. Stevens.

SATURDAY, MARCH 24.

ROYAL INSTITUTION, at 3.—The Corpuscular Theory of Matter: Prof. J. J. Thomson, F.R.S.

MONDAY, MARCH 26.

SOCIETY OF ARTS, at 8.—Fire, Fire Risks, and Fire Extinction: Prof. Vivian B. Lewes.

INSTITUTE OF ACTUARIES, at 5.—Some Aspects of Registration of Title to Land: J. R. Hart.

TUESDAY, MARCH 27.

ROYAL INSTITUTION, at 5.—The Influence of Geology on Scenery: Dr. J. E. Marr, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Continued Discussion*: The Outer Barrier, Hodbarrow Iron Mines: H. Shelford Bidwell.—The Harbours of South Africa: C. W. Methven.

WEDNESDAY, MARCH 28.

SOCIETY OF ARTS, at 8.—Coal Conservation, Power Transmission and Smoke Prevention: A. J. Martin.

THURSDAY, MARCH 29.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On the Dilatational Stability of the Earth: Lord Rayleigh, O.M., P.R.S. On the Observations of Stars made in some British Stone Circles. Second Note: Sir J. Norman Lockyer, K.C.B., F.R.S.

ROYAL INSTITUTION, at 5.—Internal Combustion Engines: Prof. B. Hopkinson.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—*Adjourned Discussion*: Electrical Equipment of the Aberdare Collieries of the Powell Duffryn Company: C. P. Sparks.—Electric Winding, considered Practically and Commercially: W. C. Mountain.

FRIDAY, MARCH 30.

ROYAL INSTITUTION, at 9.—Recent Progress in Magneto-optics: Prof. P. Zeeman.

SATURDAY, MARCH 31.

ROYAL INSTITUTION, at 3.—The Corpuscular Theory of Matter: Prof. J. J. Thomson, F.R.S.

STARS AND NEBULÆ.

The System of the Stars. By Agnes M. Clerke. Second edition. Pp. xvi+403. (London: A. and C. Black, 1905.) Price 20s. net.

THERE is much excellent sense in the French proverb, "Prends le premier conseil d'une femme, et non le second," which expresses the view that the intuitive instinct of a woman is a safer guide to follow than her reasoning faculties; and although in these days it is considered ungracious to make this suggestion, evidence of its truth is not difficult to discover in most literary products of the feminine mind. It is no disparagement to Miss Clerke to say that even she shares this characteristic of her sex, so that sometimes she lets her sympathies limit her range of vision in the field of stellar research. No doubt this disposition is exercised unconsciously, but what is an attractive instinct when applied to ordinary affairs of life is derogatory when it influences the historiographic consideration of contributions to natural knowledge.

There are many students of science who follow the trend of a writer like Miss Clerke with lamb-like sequacity, and consider it almost a presumption to express any dissatisfaction with her presentment or interpretation of scientific fact. It is a sign of weakness to occupy a position of this kind; and particularly so when the author whose views are accepted is not actively engaged in the investigation of the field surveyed. Science is not a persuasion in which personal opinion has to be respected whatever the value of the material evidence in its support. We may admire Miss Clerke's literary skill and be impressed by the brilliant periods in which she frequently encloses simple matters of fact, but, at the same time, we may be permitted to recollect that she is a bibliographer rather than an observer, and therefore her works, be they never so distinguished as literature, need only be regarded as narratives by a spectator, when the weights of the results and conclusions recorded in them are being decided. There is, as Francis Bacon knew, a vast difference between opinions based upon the study of books and papers and those derived from individual observation and experience. "Studies themselves doe give forth Directions too much at Large, except they be bounded in by experience. Crafty Men Contemme Studies; Simple Men admire them; And Wise Men Use them. For they teach not their own Use; But that is a Wisdome without them and above them, won by Observation."

This statement of Miss Clerke's position is necessary by way of excuse for the temerity of a reviewer who ventures to criticise some points in a work of such a substantial character as the present one. The book has been revised so completely that scarcely a page of it remains the same as in the original edition published fifteen years ago. In this period much new work has been accomplished, and from it Miss Clerke has selected what she considers to mark essential steps in the progress of sidereal science, to incorporate with the results previously described. The task of sidereal astronomy was formerly stated to be the investigation of "the nature, origin and relationships of sixty million stars and upwards of eight thousand nebulæ," but the numbers are now "30,000,000 stars and 120,000 nebulæ." The discovery of terrestrial helium has led to the recognition of a new stellar type having helium rays prominent in their spectra, while oxygen, silicon, and titanium are among other substances the rays of which have been identified in celestial bodies in recent years. Numerous stars have been proved by the spectroscope to be close couples; and "Prof. Campbell showed in 1902 that, among the entire multitude of stars, one in six or seven is so constituted." From spectroscopic observations, it has also been possible to determine that the solar system is moving toward an apex in right ascension $277^\circ\ 30'$ and declination $+20^\circ$ at the rate of $12\frac{1}{2}$ miles a second, the probable error of the result being less than one mile a second. The demonstration of the motion of nebulæ in the line of sight has shown that there is no difference in this respect between nebulæ and stars, and has thus removed a difficulty formerly offered to the view that stars arise from a condensation of nebulous matter. Finally, the large number of variable stars found in certain globular clusters, the phenomena presented by such temporary stars as Nova Aurigæ and Nova Persei, and the structure and distribution of nebulæ in relation to the Milky Way, can only be simply and sufficiently explained by the existence in space of clouds of obscure particles alone or associated with luminous matter. The most noteworthy discoveries of astronomical science in recent years are, indeed, those which demonstrate or suggest that space may include as much dark material as bright.

Until a few years ago it was believed that nebulæ are masses of glowing gas at a high temperature; but Miss Clerke is now able to write, "experience is wholly contradictory of the notion that nebulæ are excessively hot bodies." It is scarcely too much to say that the evidence brought forward by Sir Norman Lockyer in connection with his meteoritic hypothesis of celestial evolution is chiefly responsible for the change of view that has taken place. An astronomer unfamiliar with the literature of astrophysics would not, however, derive this impression from the study of any parts of this book in which nebulæ are dealt with. Again, it is stated that a consensus of opinion regards gaseous nebulæ as being "luminous through electrical excitement"; but though this is frequently mentioned, there is no record of the suggestion made in 1888, as the result of spectroscopic examinations of meteorites, that in the Orion nebula "the hydrogen is electrically excited"; yet this observation was recorded in the original edition of Miss Clerke's book.

The low temperature of nebulæ, electrical excitation as a cause of luminosity, and the suggestion that the apparently continuous spectrum of white nebulæ, like the nebula of Andromeda, would prove to be an interrupted band of colour, are all functions of the meteoritic hypothesis. These three points have been

 Z

specifically and repeatedly mentioned in connection with the hypothesis, as, for instance, in the remark that the general absence of bright lines of metallic vapours, and of the bright lines of hydrogen in white nebulæ "evidently justifies the conclusion that we are here in presence of those bodies in celestial space, the temperature and the electrical excitation of which are at a minimum, and as the continuous part of the spectrum is brought under examination further stages will be recognised. . . . There can be little doubt that when our instrumental appliances and observing conditions become more perfect, it will be found that the so-called continuous spectra will be a perfect mine of new knowledge regarding the true nature of the changes which occur as condensation increases" ("Meteoritic Hypothesis," pp. 323, 324).

This was written sixteen years ago; and the work that has since been done enables Miss Clerke to arrive at the same conclusions, though she has forgotten the observations which have changed the position formerly occupied. She can now write:—

"Gaseous nebulæ are, in fact, reasonably believed to be at a temperature not much above absolute zero. They are not, then, incandescent, but rather 'luminescent'; their light is independent of thermal conditions."

Also we find in several places the view accepted that even the spectra of white nebulæ are not truly continuous, but show

"slight inequalities in the flow of light, indicating effects of absorption, of emission, or of both combined."

In the present state of knowledge of nebular spectroscopy, no opinion of substantial value can be expressed as to the relationship existing between nebulæ exhibiting the characteristic line at λ 5007 alone or with other lines, and nebulæ with apparently continuous spectra, but the view that the difference is due to different degrees of condensation of congeries of meteoritic matter—cosmic dust—the Andromeda type of nebula being in a more condensed condition than an irregular nebula like that of Orion, is at least as reasonable as any other. Even if this suggestion is considered to be of negligible value, there remains the fact that the present tendency is to regard the spectra of all nebulæ as being really discontinuous, as was anticipated in the meteoritic hypothesis. Moreover, Miss Clerke admits that, apart from the question of the apparent differences between the two spectroscopic types of nebulæ,

"relationship between the various orders of nebulæ is manifest. The tendency of all to assume spiral forms demonstrates, in itself, their close affinity; so that to admit some to membership of the sidereal system while excluding others would be a palpable absurdity. And since those of a gaseous constitution must be so admitted, the rest follow inevitably."

It is not clear from this, or from other remarks in the book, how we are to regard the white nebulæ, if only as a working hypothesis. Most spiral nebulæ do not give the characteristic spectrum of hydrogen and helium, yet it is agreed that all spiral forms are closely related. If it is assumed that the spiral nebulæ with bright line spectra are entirely gaseous in constitution, it is difficult to explain the existence of apparent "stars," presumably at a higher temperature than that of the general mass of gas, threaded upon the spirals. If, however, the view is accepted that the luminous radiations of so-called "gaseous" nebulæ are really only the visible manifestations of electric or dynamic disturbances of a mass of cosmic dust—and few would now deny the existence of dark matter in nebulæ—the explanation of spiral nebulæ is easy, and the difficulty as to the relationship between these nebulæ and others disappears. The existence of streams, sheets, and shells of palpable matter intersecting at various points is sufficient to account for the bright portions of spiral nebulæ with the apparent stars arranged along the spirals; if nebulæ have this meteoritic constitution spiral forms ought to predominate, as they actually do. Spiral nebulæ like those of Andromeda and Canes Venatici are certainly not purely gaseous in constitution, though a few years ago it was more necessary to insist upon their non-gaseous nature than it is now; but while we await crucial observations to decide how nebulæ of different spectroscopic types are related, Miss Clerke might have shown that an explanation has been given, though she may disapprove of it.

A knowledge of the constitution of nebulæ is of fundamental importance, for upon it must be based any satisfactory scheme of evolution of celestial species. All astronomers accept the idea of evolution from nebulæ, but as to the order of development, and the means by which it is brought about, no hypothesis has met with general adoption, even as a working principle. A common ground of agreement, however, is that nebulæ showing the characteristic trio of lines—λλ 4860, 4950, and 5007—in their spectra are at a relatively low temperature. Given the cosmical amœba in the form of a nebula, what will become of it? The question cannot be answered directly, because sidereal ontogeny transcends human experience; but though the development of the individual nebula cannot be followed, a sidereal phylogeny can be based upon the spectroscopic characters of celestial species. Miss Clerke does not deal with nebular and stellar spectra from the point of view of development; for she takes Secchi's four types of spectra as her groups for discussion, and only makes incidental reference to the stages occupied by particular stars in an evolutionary scheme. The helium-stars, typified by certain stars in the constellation Orion, are regarded as the first results of condensation from nebulæ; Sirian stars represent the next stage, and then the solar condition is reached.

"In a general sense it may indeed be said that the spectra of the sun and of solar stars imply a state of things in their reversing layers analogous to that prevailing in the arc-light, while in helium and Sirian stars the conditions of the spark are more nearly reproduced."

From stars of the solar type, Miss Clerke suggests that the development is toward the condition of Betelgeux, which exhibits the Fraunhofer spectrum in

association with titanium flutings or bands, then to α Herculis, in which "the bands have acquired strength through the efflux of time, it is supposed, and the progress of cooling." Further than this she does not go, Secchi's fourth type of stars, showing absorption flutings of carbon in their spectra, being regarded as a class apart, and not united to the sun and its congeners in an evolutionary series.

In this classification of stellar spectra, temperature is not considered as an essential factor or a concomitant of the changes described; the question of the temperatures of the stars forms the subject of a separate chapter, new to the present edition. Heat is not entirely discarded, but "luminescence," "radiology," and "electrical excitement" now appeal to Miss Clerke's affections, and she flirts with them whenever she has the opportunity, though little is known of their resources. By this course she is able to believe, with Sir William and Lady Huggins, that solar stars are hotter than Sirian stars, while she acknowledges, as has been shown, that arc-lines are characteristic of the former type of spectra and spark-lines of the latter. Whether the temperature of the electric spark is actually higher than that of the arc has yet to be decided, but solar stars can only be placed at a higher temperature-level than white stars by neglecting much circumstantial evidence in support of the superiority of the spark. As a matter of fact, laboratory observations, so far as they are available, show that the same spectra can be produced by thermal or electrical action. Under conditions from which electrical influences were probably excluded, and the spectra obtained were due solely to high temperature, nitrogen at temperatures above 3000° C. has been found to give an emission spectrum in which the principal lines characteristic of the element were visible (Nasini and Anderlini, *Atti dei Lincei*, July, 1904). The agency by which gases and vapours are rendered incandescent seems, indeed, to be inconsequential, and high temperature is probably competent to produce the same spectroscopic results as those observed when incandescence is caused by the oscillatory discharge.

Electric and thermal effects cannot, however, be distinguished from one another in stellar spectra; therefore any attempt at a temperature classification must provide for possible electric influences. It was recognised by Sir Norman Lockyer more than thirty years ago (Roy. Soc. Proc., vol. xxii., p. 372, section ii., June, 1874) that the action of electricity must be included in the term "temperature"; and while the chemical changes effected by thermal and electric forms of energy cannot be discriminated in celestial spectra, the aim should be to construct a chemical classification without waiting for a complete understanding of the active causes of atomic vibrations or molecular combinations revealed by the spectroscope.

From whatever point of view stellar spectra are studied, little support can be found for the conclusion that the solar stars are at a higher temperature-level than the white stars. From a comparison of the spectra of Capella and Vega—typical solar and white stars respectively—Sir William and Lady Huggins concluded that "The solar orb seemed intrinsically the *bluer*, and was inferred to be the hotter of the two"; but neither the observation nor the inference can be regarded as established. Adopting the relative length of the ultra-violet spectrum as a criterion of stellar temperature, observations show that solar stars are really weaker in ultra-violet rays than white stars. In a paper on "Radiation through a Foggy Atmosphere" (*Astrophysical Journal*, vol. xxi., No. 1, January, 1905) Prof. Schuster accepts "the comparative weakness of the ultra-violet radiation in solar stars" as a fundamental fact which he attributes to molecular scattering in the photospheric regions of these bodies; but whatever the explanation, it is clear that spectroscopists have not adopted Sir William and Lady Huggins's view as to the ultra-violet spectrum of solar stars, but hold an opinion directly opposed to it. The extension of spectra into the ultra-violet may be regarded as the result of increased temperature, but by this standard white stars are placed above solar stars, and not below them.

All standards of comparison should, however, lead to the same spectroscopic succession if they are true tests of evolutionary development of celestial species. The sequence derived from comparisons of the lengths of ultra-violet spectra is the same as that revealed by the presence of gaseous and metallic lines of helium and hydrogen, and the enhanced and arc lines of the metals. In stars which have relatively the longest ultra-violet spectra there are few absorption lines; iron is represented practically by the enhanced lines alone, and the lines characteristic of the arc spectrum are almost or entirely absent. Only by considering the length of the ultra-violet spectrum together with the presence or absence of iron lines and lines that are intensified in passing from the condition of the arc to that of the spark can a useful classification of stellar spectra be established. When this principle is adopted a chemical classification of spectra becomes possible, and a reasonable scale of stellar thermotics is arrived at. From a hot star like Bellatrix a descending series can be arranged through β Persei, γ Lyræ, Sirius, Castor, and Procyon to Arcturus—a relatively cool star—by considering the changes in the spectrum of any constituent in passing from one grade to another. A continuous ascending series of spectra reaching up to Bellatrix can also be arranged from the spectrum of nebulæ of the Orion type through planetary nebulæ and the Wolf Rayet stars showing the line λ 4688 in their spectra to Orion stars in which this line is dark. This arrangement of spectra corresponds also with the sequence which would be expected as the result of various degrees of chemical dissociation at different temperatures. Stars having the smallest number of chemical elements represented in their spectra are probably the hottest, while an increased number of lines in other spectra is probably due to the existence of an increased number of chemical elements as the result of lower temperatures, the inferior position on the temperature scale being indicated also by the reduction of the relative length of the spectrum, increase of the relative intensity of red radiation and general absence of

enhanced lines. Little is said about this chemical classification by Miss Clerke, and nothing in its favour, yet it represents the conclusions of a lifetime devoted to the study of spectra in the laboratory and observatory, and abundant material relating to it appears in the Proceedings of the Royal Society. Anyone unfamiliar with this material who reads what Miss Clerke has to say upon the temperatures of the stars and the interpretation of stellar spectra would have an inadequate idea of the results of systematic studies of these subjects, or of the existence of substantial ground of appeal against her verdict.

An instance of an incomplete statement that tends to mislead the reader is afforded by the note on Sir William and Lady Huggins's experiments on the behaviour of the H and K lines of the spectrum of calcium (Roy. Soc., June 17, 1897). By reducing the density of calcium vapour the lines H and K were obtained alone, and it was concluded that the various appearances of calcium lines in celestial bodies were due to the different states of density of the gases from which the lines were emitted or absorbed, and not to degrees of dissociation. The H and K lines in the solar spectrum are considered to prove the existence of "the metal calcium in a highly rarefied state"; and upon this evidence, referring to the condition of this element, Miss Clerke remarks:—"The hypothesis of its dissociation in the sun thus remains unverified." As a matter of logic, the experiments only prove that the H and K lines of calcium are spectroscopically persistent, and were able to survive (as might have been expected) conditions which effaced weaker lines in the spectrum of the element. Because brachiopods belonging to the genus Lingula are found in the sea at the present day as they were in Palæozoic ages, while many other forms that were contemporary have disappeared, we do not conclude that organic evolution is impossible, but only that the organism represents a type which persists in spite of changes of conditions. In the same way the continued existence of the H and K lines affords no evidence whatever against the view that there are different molecular groupings of calcium at different temperatures. By reducing the density of the calcium vapour, Sir William and Lady Huggins reduced the quantity acted upon; so the dissociated condition represented by the appearance of H and K alone was reached sooner. Similar experiments were made by Sir Norman Lockyer in 1879, and the conclusion arrived at was that a reduction in the quantity of a substance generally simplifies the spectrum. "In all probability the effects hitherto ascribed to quantity have been due to the presence of the molecular groupings of greater complexity. The more there is to dissociate, the more time is required to run through the series, and the better the first stages are seen" (Roy. Soc. Proc., vol. xxx., p. 26).

It will be seen, therefore, that the principal point of Sir William and Lady Huggins' experiment on calcium vapour at different densities was the subject of laboratory experiments more than twenty years earlier, and that their conclusion, though it is mentioned by Miss Clerke without reservation or reference to previous investigations, is not a safe one to apply to the consideration of the condition of calcium in the sun or stars as indicated by spectroscopic appearance. Moreover, if the changes of the calcium spectrum are interpreted as effects of tenuity, the similar spectral variations of magnesium and iron ought to admit of a like explanation, whereas there is good evidence that they are due to constitutional changes brought about by thermal or electric action.

Many other debatable matters are dealt with by Miss Clerke in a manner which suggests that the last word has been said upon them when she is really only presenting one side of a case. It may be assumed that, like a good advocate, she is as familiar with the defendant's case as she is with the plaintiff's, but the real strength of the evidence opposed to the views she adopts could only be shown by the disciple of another school of spectroscopy; and a small volume would be required to plead this cause. No writer on astronomy has a more facile pen than has Miss Clerke, and we can forgive the occasional florid style when we remember the vast amount of reading and careful analysis involved in the preparation of a volume of this kind. The work is so good that every student of astronomical physics must be familiar with it, and every astronomical library must include it. Because of its essential qualities it is to be regretted that a broad view has not been taken of all contributions to the subject made by competent investigators; for by neglecting such aspects as have been referred to in the foregoing paragraphs an incomplete story is presented of the meaning and mysteries of sidereal development revealed by spectroscopic research.

R. A. Gregory.

BRITISH ASCIDIANS.

The British Tunicata: an Unfinished Monograph. By the late Joshua Alder and the late Albany Hancock. Edited by John Hopkinson, with a History of the Work by the Rev. A. M. Norman, F.R.S., &c. Vol. i. Pp. xvi+146+xx plates. (London: Printed for the Ray Society, 1905.) Price 12*s*. 6*d*. net.

THERE are probably few precedents for the publication of an unfinished biological monograph thirty years after the authors penned their last remarks, especially of a monograph dealing with a group which has been the object of much detailed investigation by other hands in the interval. The chequered history of the present work is briefly, but sympathetically, told by Canon Norman, from whose preface the following paragraph may be extracted:—

"Though so many years have elapsed, the value of this Monograph is great, since (1st) it contains full descriptions with illustrations of the Tunicata of our fauna as known up to the time of the death of the authors; (2nd) because many of the new species had been only briefly diagnosed, and the fuller descriptions and figures of these which are now given will enable them to be better known and understood; and (3rd) it is especially desirable that the full account of Hancock's investigations should be published together with a portion of his beautiful drawings."

For these reasons the student of the Tunicata cannot be otherwise than grateful to the Ray Society for the publication of this work, and especially for the liberality with which it has been illustrated. The coloured figures representing many of the authors' species must rank among the best figures of ascidians extant, and the numerous collotype reproductions of Hancock's drawings of the branchial sac, &c., will greatly facilitate the task of identification.

The first volume, which we hope may soon be followed by the remainder of the work, contains (1) the authors' introduction (a historical summary of British records of Tunicata up to the year 1870), (2) a reprint of Hancock's paper "On the Anatomy and Physiology of the Tunicata" (published by the Linnean Society in 1867), and (3) an account of thirty British species referred by the authors to the genus Ascidia. Two of these so-called species are now described for the first time, viz. *Ascidia amoena* and *Ascidia Morei*.

It is no discredit to the memory of the distinguished authors of this monograph, whose general accuracy of observation has long been established, if we express a conviction that no modern expert in this group of marine animals will be prepared to recognise the claims of half Alder and Hancock's "species" to specific rank. It is not improbable that the thirty forms described in the monograph will be ultimately referred to some ten or twelve "good species" at most.

Excluding *Ascidia canina*, the relations of which to *Ciona intestinalis*, L., appear, strangely enough, to have been overlooked by Hancock, the remaining twenty-nine species of Ascidia, as described by the authors, would in these days be referred to the three genera Phallusia (with the single species *mamillata*), Ascidia and Ascidiella of Roule. Adopting for the moment Alder and Hancock's specific names, and confining our attention to the forms dealt with in their monograph, we may say that each of the genera Ascidia and Ascidiella includes three main types. To Ascidia (*s. str.*) belong (1) *mentula*, with which *robusta*, *rubicunda*, and *rubrotincta* are probably synonymous; (2) *mollis*, with *crassa*, *plana*, *Alderi*, and possibly *rudis*, as allies; and (3) *plebeia* (=*conchilega* of Müller), with which *producta*, *inornata*, and *depressa* are closely related or synonymous. To Ascidiella belong (1) *obliqua* (=*prunum* of Müller), to which the new species *amoena* appears to be related; (2) *venosa*, and (3) a large series of very variable forms referable in the main to the types *sordida* (=*virginea* of Müller), *scabra*, and *pustulosa* (=*aspersa* of Müller), of one or other of which the authors' "species" *elongata*, *aculeata*, *Morei*, *Normani*, *affinis*, *elliptica*, *pellucida*, *orbicularis*, and *vitrea* appear to be merely varieties or local forms.[1]

There is probably no group of animals in which external conditions exert a greater influence upon the size, shape, and structure of the body than in the case of the ascidians, owing to their permanent fixation under the most diverse natural conditions, their mode of feeding, and the plastic character of the test which serves them for a skeleton. Differences in the supply of food alone—and no factor is liable to greater extremes than the amount of phytoplankton in littoral waters—must influence the development of an ascidian's body in so many different ways that great variability must be the rule rather than the exception. In these circumstances it is doubtful if the natural history of this group can be adequately treated in any monograph until much additional work has been done, not only in the systematic observation of the nature and extent of local variations, but also in direct experiments concerning the effect of different conditions upon the growth of the progeny of selected parents. Until such work has been done, any attempt to define specific limits within (*e.g.*) the *virginea-scabra-aspersa* group must remain a mere expression of personal opinion.

In the meantime the publication of the present work is likely to lead to the clearing up of many uncertainties, provided it is regarded mainly as a repository of facts, and not as an authoritative guide to the classification or nomenclature of the group.

This aspect of the work has been fortunately retained under the editorship of Mr. Hopkinson, who has restricted his notes to the addition of such bibliographic and distributional records, published prior to 1871, as were necessary for the completion of the authors' MSS. up to the date of Hancock's latest work. The editorial footnote "on the intimate relationship existing between the Tunicata and the Polyzoa," on the first page of the authors' introduction, conveys just the right touch of archaic suggestiveness.

We notice a couple of misprints: Weigmann for Wiegmann (pp. 7 and 12), and Mongula for Molgula (p. 46); and may point out that Figs. 8 and 9 on plate xi. represent not "probably a variety of *Corella parallelogramma*," but Hancock's own species, *Corella larvaeformis*, which we presume will be described in the second volume of the monograph.

W. GARSTANG.

[1] For a fuller discussion of the relations of particular species special reference should be made to Prof. Herdman's paper in *Jour. Linn. Soc.*, xxiv., 1893, and Hartmeyer's "Holosome Ascidien" in "Meeresfauna von Bergen," 1901.

THE METALLURGY OF IRON AND STEEL.

Elementary Practical Metallurgy, Iron and Steel. By Percy Longmuir. Pp. xiii+270+13 plates. (London: Longmans, Green and Co.) Price 5s. net.

WORKS on practical metallurgy have generally consisted of descriptions of series of experiments suitable for performance in an ordinary laboratory possessing the usual equipment with small assay furnaces; but this book is an elementary work on the metallurgy of iron and steel, written with the view not only of serving the needs of the ordinary beginner among students, but of attracting the severely practical man to the study of metallurgical literature, and thus helping him ultimately to the position of being able to throw the light of new discoveries on his daily work, and to make application of suitable results—evidently a practical apostle of the methods of the British Science Guild. The writer thoroughly agrees

with the author that "Such a work should not be overloaded with detail, but the facts presented should be accurate and the matter reliable," for nothing more certainly repels the very specially practical man than a mass of finical hedgings, which are only fit for discussion among philosophers, but do not affect the main present issues. While this is so, looseness of expression is the last thing to permit oneself, as no type of man more appreciates accurate statements if they are simply expressed. While the author has in the main succeeded in his ideal, there are some points which the writer would change. Thus, p. 7, "Elasticity . . . is the length to which . . . ." Similarly, tenacity, breaking load, ductility, and ductility as applied to wire-drawing are not satisfactory. Interesting and simply written chapters on refractories, iron ores, and the blast furnace follow. The author's wide practical experience in foundries lends a special interest to his chapters (vi. to ix.) on pig- and cast-irons, for in the works he was daily brought into contact with the adjustment of those properties of cast-iron to the fulfilment of the orders on hand, and this may account for his almost bitter treatment of the enemy, sulphur, which is perhaps not quite so black as he has painted it.

These chapters should also show why there is such a fascination in the study of this complicated material. Next comes a good chapter on malleable cast-iron, but a statement on p. 128 is a little confusing. British malleables are said to contain something like 0·3 per cent. S, which agrees with the writer's experience. Then it is stated that grey hæmatite refined is used, but this would really contain less than 0·1 per cent. S. The fact seems to be that a material called refined hæmatite, but really white hæmatite re-cast into small pigs, is used, and the old refined grey pig is not obtainable on the open market.

In comparing the Siemens and Bessemer processes, the important point of the much smaller percentage of loss in the open-hearth seems to have been omitted. The crucible, Bessemer, and open-hearth processes are described in considerable detail, and p. 227, on the production of sound steel, is excellent, while it was only to be expected from the author's researches that the influence of casting temperature would be adequately dealt with. Chapters xviii. and xix., on the metallography of the heat treatment of steel and of hardened steels, are profusely illustrated, and deal with the subject from the carbonist's point of view, with the intimation that there are other theories, a wise decision, as whichever of the many theories may prove to be the correct one, that given is the easiest to understand, and the reader may search out the others if so minded. The author, in using for illustration microsections of articles he has used, such as hack-saw, table-blade, razor, and file, sets the seal on his desire to attract the practical man, and if on examining similar tools he should find different structure it ought to stimulate inquiry. The final chapter on special steels, while good in itself, will impress on the reader that there is much—very much—more beyond. The work, which is printed on matte surface paper, most agreeable to the eye, with thirty-one of its sixty-four illustrations printed on smooth paper to bring out the required detail, can be recommended to the beginner as a "book which will primarily awaken interest."

A. McWilliam.

OUR BOOK SHELF.

Glue, Gelatine, and their Allied Products. By Thomas Lambert. Pp. xii+153. (London: Chas. Griffin and Co., Ltd., 1905.) Price 5*s*. net.

This is a handbook intended for the use of glue manufacturers, agriculturists, and students of technology. It describes the preparation and properties of glue and gelatin, and also of certain side-products, such as size, cements, and fertilisers. The description is written chiefly from the practical standpoint, though some notes on the chemistry of the products are included. Diagrams of plant and machinery illustrate the working of the various processes mentioned in the text.

While the book contains much trustworthy information, there is some confusion in its arrangement. Thus the first chapter purports to be "historical," but it deals principally with matters quite other than historical; as, for example, "chondrin and its properties," "railway accommodation," "water supply," and so on. Moreover, it would, we think, have been better if the author had written either specifically for manufacturers or specifically for the manufacturing chemist, instead of addressing himself sometimes to the one and sometimes to the other. The manufacturer, for instance, hardly wants a detailed description of Kjeldahl's method of determining nitrogen; on the other hand, the chemist might well be spared the statement that "all crops contain certain mineral matters in their ashes."

The book would form a good nucleus for better things. With some re-arrangement of its subject-matter, and a less superficial treatment of the chemistry involved, it might develop into an excellent manual of the technology of glue and gelatin.

C. S.

Webbia-Raccolta di Scritti Botanici pubricati in occasione del 50° anniversario della Morti di Fillipo Barker Webb. Edited by Prof. U. Martelli. Pp. xi+393. (Florence: S. Pellas, 1905.)

Philip Barker Webb, in whose honour this volume has been compiled, lived in the first half of last century; during his career at Oxford he developed a taste for the classics and natural history which a substantial patrimony allowed him to cultivate. In the course of his travels he visited Spain, Portugal, the Canary Islands, and other countries, combining botany and geology with pleasure. He resided generally in Paris during the intervals between his journeys, and there he directed and carried out the work in connection with the "Phytographia Canariensis"; also he accumulated a large herbarium, including several French collections. At his death his botanical treasures were lost to France, as he bequeathed all his plants and books, together with a sum of money for their maintenance, to the Grand Duke of Tuscany.

This volume contains a number of original papers that have been contributed by Italian botanists as a token of gratitude for the stimulus which these collections have given to Italian botany. Most of the papers are concerned with systematic botany. Prof. O. Beccari, writing about palms, contributes an account of the Indian genus Trachycarpus, allied to Chamærops; a list of species from New Guinea, in-

cluding a new genus, Barkerwebbia, under the Arecineæ, and a revision of the order for the Philippines. Prof. U. Martelli describes a number of new species of Pandanus. A review of European umbellifers, in which the writer includes the Araliaceæ, forms the subject of a lengthy paper by Dr. B. Castellani. Prof. E. Bartoni publishes a short MS. by Parlatore on Linnæus's herbarium which is especially appropriate, as Webb and Parlatore were friends, and held each other in mutual esteem.

A Course in Mathematical Analysis. By Édouard Goursat. Translated by E. R. Hedrick. Vol. i. Pp. viii+548. (London and Boston: Ginn and Co., n.d.) Price 16*s*.

This readable and trustworthy translation will be welcome to those who cannot enjoy the original, the merits of which are by this time well known. The typography is unusually good, and is very creditable to all concerned, such symbols as the square of a_1, or even of a', being printed in a satisfactory way, which English printers might imitate with advantage. There are a few terms here and there which are ungrateful to an English ear; "involutionary" or "involutional" would be more agreeable to analogy than "involutory," and "nappe" is retained instead of being rendered by "sheet." But these are trifles, and those of us who have no French can now study a treatise which is eminently lucid and attractive, as well as being up to date and sufficiently rigorous for the purpose it is designed to fulfil.

Agriculture and the Empire.

The article by Sir W. T. Thiselton-Dyer in your issue of March 22 is a fair statement of the position the Home Country should take in the development of agriculture in the Empire at large, and of the necessary training the future experts and researchers in Indian agriculture should receive; and this view requires pressing upon those responsible for the development of agriculture in our colonies, so that the policy of employing as agricultural experts men with a mere smattering of scientific method, combined with a more or less thorough knowledge of British agriculture, may not be followed. Investigation and careful research are wanted, and the only men who can perform this are those whose sense of proportion and scientific methods of attack have been developed by a systematic training in the sciences having a bearing on agriculture. Agriculture is at once a science, an art, and a business, and the successful agriculturist at home must be a man equipped with an adequate knowledge of all these subjects, combined with a special ability for one or more of them.

The agricultural colleges of Great Britain afford a training in the science and art of agriculture, but on the business side of the subject not much can be attempted, as personal experience and responsibility of the individual for his business transactions are necessary conditions. Many agricultural colleges and agricultural departments of our universities possess the necessary scientific equipment and a staff of adequate attainments to give to the future Indian or colonial expert a thorough systematic training in such sciences as chemistry, botany, and zoology, in an agricultural atmosphere. The latter condition must be of immense importance in impressing on the student the relations of the pure science to practice: and although the practical application he will experience abroad will differ essentially from that observed at home, he will at all events be prepared to use his science to solve problems of economical value, and, if his training has been broad and thorough, to become a most useful factor in developing the agriculture of the country. It is certain that a man trained at an agricultural college or at an institution equipped with the necessary facilities for the study of animal or plant life will be better able to enter upon his duties as investigator of agricultural science in India than a man whose training has been received at the ordinary technical college. From the staff and students of this college during the past few years experts have gone: to South Africa, four, including the director of the Transvaal Agricultural Department; to India, four, including two to Pusa; to British Guiana, the West Indies, and Egypt, two, as well as to other countries, so that it can claim some connection with agriculture in our colonies.

Sir W. Thiselton-Dyer says that notice should be given five years in advance of the requirements for trained men; with this opinion I agree, though I doubt its practicability. What we require is more men of recognised ability to train for such position. Hitherto some branch of technical work other than agriculture has been the object, to a great extent, of the trained student, but now that there is a future for highly trained men who will bring their scientific knowledge and spirit of investigation to bear upon the problems of agriculture at home and abroad, we hope that men of the right stamp will come to be trained partly perhaps in this country, and afterwards under the conditions in which their future work will lie, but in any case to go through a complete course of systematic study in the science to which they intend to devote themselves when they have gained their technical experience. It is a fact, and one to be deplored, that the agricultural students are not always drawn from the best of our rising generation, since farming is looked upon as the profession to be engaged in by those "who are too clever for the Army and not stupid enough for the Church"; but now that we can offer a field for a well trained man to make a name and a living in the domain of agricultural research, we should secure a greater proportion of suitable men. In this country, for the researcher, apart from the teacher, there is little chance for a trained man to earn a livelihood, but abroad, where the resources of the soil have yet to be developed, there is a good prospect of employment for men who are thoroughly equipped with the requisite scientific knowledge and possess the spirit of investigation.

Another point to which Sir W. Thiselton-Dyer has directed attention is the proper teaching of science in our rural elementary schools, and, I would add, our rural secondary schools. How often do we see, especially in the latter class of school, the teacher (who is often selected for his chemical knowledge) teaching by book alone, and without reference to the conditions amid which his scholars live. Chemistry is one of the least suitable of the natural sciences to teach children whose lives will be, or ought to be, spent in the country. Botany or zoology taught by a teacher who has learnt these subjects, and has been trained in their application to outdoor life as it exists in an English farm or country village, would be far preferable, and I venture to think that Kew, the agricultural departments of our universities, and our agricultural colleges could supply such teachers, and so could influence to a considerable extent the value of the teaching in country districts.

The Board of Education has, I understand, the latter matter in hand, and I trust that under the advice of their excellent rural inspector a scheme will be formulated which will in some way check the tendency of modern education to prepare solely for town life. M. J. R. Dunstan.

South-Eastern Agricultural College (University of London), Wye, Kent, March 26.

Sea-sickness and Equilibration of the Eyes.

Many people have no doubt noticed, when travelling by sea, that the motion of the ship could be *seen* very distinctly, even when there were no hanging lamps, draperies, or fixed points, such as the horizon or clouds, within range of sight.

Some may think that seeing the motion in this way is due to the imagination receiving its suggestions from the motion of the internal organs, and especially the stomach, for I am here supposing the body to be held perfectly rigid.

From observations which I have recently made it seems evident to me that the cause for seeing the motion is entirely different.

In the first place, you can always see the motion a fraction of a second before you begin to feel it. In the second place, you cannot see a perfectly horizontal motion or a gentle vertical (heaving) motion. In the third place, watching a fixed point close to you, such as a pattern on a carpet, when the ship is pitching and rolling, is far more tiring to the eyesight than when the ship is motionless or running perfectly steadily. All this points to the appearance being due to a true relative motion of the eyes to the ship.

The eyes are suspended in their muscular settings, much in the same way as are ships' compasses in their binnacles. The eyes are, furthermore, perfectly balanced, so as to make their muscular displacements as little tiring as possible. In their normal position, the pull of gravity is exerted vertically through their centres, and the muscular mechanism is compensated for gravity.

Any angular change of position will displace the eyes just as it displaces the stomach, excepting that the eyes, being a great deal more sensitively suspended, will register the displacements more quickly. It is not, however, the motion of the eyes which strains the eyesight, but the act of resisting this motion.

If, with your eyes shut, you attempt to fix the mental representation of a point, which a moment previously you were watching with eyes wide open, you will find that, after one or two motions of the ship, the bodily feeling will precede any visual sensation which your imagination can conjure up. The imaginary point is no longer fixed, but follows the eyes as they let themselves go to the motions of the ship. No strain of the eyesight is caused by a muscular resistance, and the displacements, while felt, can no longer be seen.

ALFRED SANG.

Pittsburg, U.S.A., February 26.

Production of an Electrically Conductive Glass.

EXPERIMENTS have from time to time been made, both in England and abroad, to ascertain what ingredients are best for the purpose of producing glasses of very high electrical resistance.

The utility of a vitreous substance which would conduct electricity comparatively well does not appear, however, to have so far claimed any consideration.

I beg therefore to direct attention to a glass which has recently been made in my laboratory. Its chief feature is that it readily conducts electricity.

For the windows or cases of electroscopes and all high-tension apparatus requiring a transparent cover capable of screening off external electrical fields, this material offers many advantages. A conducting varnish is no longer required for glass which conducts electricity itself. In addition to these practical considerations, there arises the interesting question as to the process by which electricity passes through this substance—whether it is electrolytic. Its resistance varies very markedly with temperature changes. I hope later to give more precise details. The basis of the glass is sodium silicate.

Shooters Hill, Kent, March 12.

Interpretation of Meteorological Records.

IN discussing the records of the meteorological instruments at Canterbury (NATURE, March 15), Dr. Aitken suggests that the heavy rain which fell dragged down the higher air, and so caused the fall of 12° indicated on the thermograph curve, and he very clearly and convincingly shows the consequent effect on the barometric pressure and wind velocity. If, however, the air had been in a state of stable equilibrium previous to the thunderstorm, the effect of such a mechanical dragging down of the higher air would have been to heat by compression that air so much that the temperature would have been raised rather than lowered at the ground-level. But if, previous to the storm, the upper air had from any cause become very much colder than the lower air, the atmosphere would be in a state of unstable equilibrium, that is to say, the rate of change of temperature with height would be greater than the adiabatic rate of change due to heating by compression of descending air. In such a case the changes recorded by the various curves may have been initiated by this heavy cold air suddenly descending and displacing the lower air, which by its sudden uprising would be cooled, the moisture in it condensed, and a heavy fall of rain caused.

The lightning which accompanied this storm introduces an element of uncertainty into any attempted explanation, for we do not know yet the manner in which electric charges are generated in the atmosphere. But it seems probable that a great cooling of the higher air is an accompaniment of a state of electric tension, for it is difficult to see otherwise why a thunderstorm should be followed by a lowering of the temperature near the ground-level.

Edinburgh.

Oscillation of Flame Cones.

I SHOULD be glad if any of your readers could give an explanation of the cause of the following flame phenomenon, produced while experimenting with a modification of Prof. Smithells's apparatus for the separation of the cones of a Bunsen flame.

A mixture of gas and air is burned at the top of a vertical tube (made preferably of combustion tubing) about 4 feet long and $\frac{7}{8}$ inch to 1 inch in diameter, having a delicate screw adjustment for regulating the proportions of gas and air.

The air supply is carefully and slowly increased, until an almost explosive mixture is reached, and the inner cone is very short and sharp and of a light green colour. On admitting a very slight increase of air after this point, the inner cone (sometimes the two cones) descends the tube to a distance of about 2 feet, and then pauses and goes up again, re-joining the outer cone. The flame then "sharpens" again and repeats the process, and will continue to do so for several hours without further adjustment of the gas or air being made.

There is every appearance of an explosion wave being propagated, as shown by the increasing velocity of the descending flame and by the occasional emission of a note as it reaches the end of the travel.

The length of travel can be regulated by the amount of air admitted, varying from 1 or 2 inches to about 2 feet in the same tube. If it be allowed to exceed a certain limit the inner cone is extinguished at its lowest point, but immediately re-lights at the top of the tube, and then returns as before. The periodicity can be varied from about once in five seconds to once per second.

The gas pressure does not need any special regulation, the ordinary variations from a town supply not affecting the results.

The following are the points requiring explanation :—

(1) As the proportions of gas and air are constant, what is the cause of the periodic "sharpening" of the cones after meeting at the top of the tube?

(2) What prevents the explosion wave being completed, and the consequent firing back of the mixture?

(3) What causes the inner cone to return and travel up the tube, re-joining the outer one at the top?

(4) The alteration in the character of the flame (in view of the fact that the proportions and pressure of gas and air are constant) points to some form of wave motion bringing the molecules into closer contact. If this be so, what are the conditions which set up this wave motion and what determines its periodicity?

HAROLD E. TEMPLE.

Olton, Warwickshire.

THE phenomenon described in the foregoing letter is in part dealt with in a paper by Dr. Ingle and myself in the Transactions of the Chemical Society for 1892 (vol. lxi., p. 204). The continued oscillation of the inner cone is, I think, explained by the fact that the mixture of gas and air in the tube is not uniform. We have, indeed, found it necessary to use elaborate mixing appliances to make it uniform. When a portion of the mixture rich in air reaches

the top of the tube the inner cone is propagated through it and descends until it reaches a stratum richer in gas, when it re-ascends. The fluctuation in the composition of the gaseous mixture escaping from a Bunsen burner can be seen by the throbbing of the inner cone, when the air supply is considerable. I may add that in the construction of burners for the incandescent mantle great importance is attached to the perfect mixing of gas and air, since it becomes possible thereby to have a steady flame with a relatively large quantity of primary air.

The University, Leeds. A. SMITHELLS.

Gas for Heating and Lighting Laboratories.

I SHALL be greatly favoured if you will inform me which are the best "gas-making plants" for supplying a laboratory with gas derived either from coal, or paraffin oils.

Do you know anyone who has had experience of these? I more particularly incline to those easily managed and maintained, simple and inexpensive. ALEX. PARDY.

Lynne House, Albyn Lane, Aberdeen, March 7.

IF I were fitting up a large laboratory I should put in a small water gas generator and inject paraffin oil into the fuel during the period of steaming, fixing the hydrocarbons in the gas produced by passing through a superheater.

I see in the Journal of the Society of Chemical Industry for February 28 a paper by Masumi Chikashige, who had been fitting up the Kyoto University laboratory with a gas made in this way, and of which he gives the results, which appear to be very satisfactory. In the discussion upon the paper your correspondent will also find some useful hints as to the fitting up of laboratories with heating-gas where coal-gas is not available.

If he should not require enough gas to make a small carburetted water gas plant successful, and if he can get petrol or benzene, he will probably find carburetted air the cheapest thing to use. VIVIAN B. LEWES.

Royal Naval College, Greenwich, S.E., March 12.

Cooperation between Scientific Libraries.

As this subject has recently been receiving attention in NATURE, it may interest some readers to know that the Royal Society of Edinburgh is taking steps for the purpose of finding out what can be done so far as the south of Scotland is concerned. A committee, of which I am convener, has been appointed by the council, and this committee is at present engaged in obtaining information from the various libraries of Edinburgh and Glasgow. It is hoped that later on a conference will be held, at which suggestions for joint action would be considered, and an endeavour made to draw up a scheme of cooperation for consideration by the various societies and institutions directly concerned.

I shall be very glad to supply information regarding the work of the committee to anyone who is specially interested in it, and also to receive particulars of any similar work which is being undertaken elsewhere.

HUGH MARSHALL.

University of Edinburgh, March 26.

THE PROBLEMS OF GEOLOGY.[1]

THIS admirably printed book deserves description rather than criticism, since the author, in his wide range of personal observation and reading, aptly plays the critic to the views that he successively propounds. With an unnecessary assumption of modesty, he apologises in his preface for "the clumsiness of a geologist, who is more at home with the hammer than the pen." We can scarcely believe that one who has tinged even his most serious scientific contributions with the high attraction of literary style can in reality know so little of himself. Almost all the papers in the present volume state a proposition and sustain an argument. There is, perhaps, a lighter one, describing a visit to the Lipari Isles; but even this contains a theoretical explanation of a difficult problem at the end. Yet the book is entirely readable, and will serve to bring to workers in all manner of fields the views of one who holds that nothing terrestrial is foreign to the subject of geology.

The papers are of various modern dates, and might, as we venture to think, have been brought nearer to uniformity in the text itself. Corrections are introduced in footnotes; but essays need not be treated as prize-poems, to be crowned with honour, and to remain unalterable. We do not want to read, for instance, that "the boring party is at this moment at work" on Funafuti, when evidence is immediately given that the task was completed seven years back. But this is a matter of pure detail; the scientific considerations put forward are uniformly fresh, vigorous, and inspiring.

The article on "The Age of the Earth" naturally brings us to no definite conclusion, seeing that the data on which a correct judgment depends are still of the scantiest description. A large number of readers, however, rejoice in such discussions; and we even discern grounds for combat when we are asked to believe that the opening of the fossiliferous stratified series lies only twenty-six million years behind us. In the following paper, on "The Figure of the Earth," we are introduced, as general readers, to Mr. Jeans's very recent hypothesis of a pear-shaped primitive earth, and a secondary pear-shaped earth with an equatorial bulge. Lest we should pin our faith to these or any other proposed forms, we shall do well to notice the excellently chosen language in which the author places them before us. In the discussion of the earth's loss of heat, radium is held up to us (p. 63) as "threatening to destroy all faith in hitherto ascertained results, and to shatter the fabric of reasoning raised upon them." Now and again, therefore, we suspect in Prof. Sollas the artist who feels in him a mission to produce and paint, even if in perishable pigments. The pigments are not his fault; they are all that others will provide for him; but the artist in him must find expression, spite of all. After this, dare we revert to the passage in the preface in excuse of "the clumsiness of a geologist"?

The summary of the results of the famous Funafuti boring is very welcome, especially in view of the cautious absence of generalisations that characterised the Royal Society report. It is a matter of regret that von Richthofen should have passed away without reading the authoritative re-vindication of his views as to reefs in Tyrol contained on pp. 131 and 132 of the present volume.

The sixth chapter, on "The Origin and Formation of Flints," should set at rest many fantastic theories still prevalent among amateur geologists. We only wish that the numerous flints of radiolarian origin could have been included in this lucid essay. Zoologists will be especially attracted by the next chapter, on "The Origin of Freshwater Fauna" (faunas?), in which Lake Tanganyika, among other areas, is discussed. William Smith's views on the contemporaneity of similar faunas are defended in "The Key to Terrestrial History"; and an address on "Geologies and Deluges," in which objection is properly taken to Suess's reliance on the Chaldæan narrative of the deluge, concludes the varied and uniformly interesting series.

If we accept "planctone"—but would the author write "gnomone"?—the only slips that we notice in this excellent book are in proper names, Burnett,

[1] "The Age of the Earth, and other Geological Studies." By W. J. Sollas, D.Sc., F.R.S. Pp. xvi.+328. (London: T. Fisher Unwin, 1905.) Price 10s. 6d. net.

Huddleston, Birnham, and Mojsisoviks. The quotation from Tennyson on p. 233 has got astray, mainly in punctuation.

In conclusion, we would ask attention to the remarkable *tour de force,* or rather *tour d'esprit,* entitled "The Influence of Oxford on the History of Geology" (p. 219). In this, Plot's work as a "critic" is compared with that of Steno as a "prophet"; Kidd, an Oxford chemist, appears to be regarded as having furnished a serviceable brake to the wheels of Hutton's chariot; while Buckland's abandonment of the Noachian déluge as a geological factor, only to accept several deluges in place of it, is held up as a claim upon our gratitude. Here we think we see Prof. Sollas revelling in his mission as an artist; yet he paints far too frankly, and has no desire to deceive us. The pigments have been made in an ancient university; but we see right through the picture. We still prefer what we may consider as the first draft of this address, a modest pamphlet issued in Bristol in 1883, in which stress is laid on the progress of geological thought rather than on the benefits to be derived from its academic retardation.

FIG. 1.—The Sella Mass, Tyrol, the remains of a supposed ancient coral atoll. (From "The Age of the Earth, and other Geological Studies.")

THE NATIONAL PHYSICAL LABORATORY.

THE annual meeting of the general board of the National Physical Laboratory was held at Bushy House on Friday, March 16. There were present, in addition to the chairman, Lord Rayleigh, the following among others:—Sir John Wolfe Barry, Mr. Beilby, Mr. Kempe, Mr. R. K. Graye, Colonel Crompton, Mr. Hadfield, Mr. Gavey, and Mr. Howard.

In opening the proceedings, Lord Rayleigh referred to the great loss the laboratory had sustained by the deaths of Sir E. Carbutt and Sir B. Samuelson.

The report of the executive committee for 1905 was presented and approved for presentation to the Royal Society on the motion of Sir J. Wolfe Barry, seconded by Mr. David Howard. The scheme of work for 1906 was also approved. The report showed progress in all directions.

Some fourteen scientific papers of importance have been published officially, while members of the staff have contributed nine others to various journals.

The second volume of "Collected Papers" is in course of preparation. The scheme of work for 1906 includes a research into the resistance of materials of construction to impact, the continuation of the wind pressure and steam researches, the completion of the work with the Ampere balance, and some experiments of great interest on the effect of the continued application of high pressure to insulators. In the metallurgical division a research into the properties of aluminium bronze promises interesting results.

The report announced the intention of the Government, communicated to the Royal Society in December last, to grant a sum of 5000*l.* for buildings during the year, and the increase of the annual grant by 500*l.* It referred also to the very successful meeting in the House of Commons last August, under the chairmanship of Mr. Haldane, which led up to a petition, signed by 150 members of the House, asking that the grants should be increased, and the chairman was able to announce that the Chancellor of the Exchequer had recently intimated his intention of making the building grant for the year 10,000*l.* instead of 5000*l.*, as originally contemplated. We are able to add that this increase was largely due to an appeal to the Chan-

cellor of the Exchequer by Mr. Haldane as president of the British Science Guild.

It was also stated that the Goldsmiths' Company had very generously made a donation of 1000*l.*, with the request that it should be devoted to some specific object.

The very cordial thanks of the board were voted to the Chancellor of the Exchequer, Mr. Haldane, Sir J. Lawrence, Sir J. Brunner, and the other gentlemen who had interested themselves in the House of Commons petition, and also to the Goldsmiths' Company.

The director gave an account of the proposed additions to the buildings rendered possible by the increased grant, and explained the plans which had been prepared by the building committee. The suggestion that the work of erecting these buildings should now be pressed forward was cordially welcomed, and at a meeting of the executive committee held later power was given to the building committee to take the necessary steps. The board then adjourned to inspect the laboratory and to view the new electrical buildings, which are now approaching completion. They have been erected by Messrs. Mowlem and Co., at a cost of about 8000*l.*, to the design of Messrs. Mott and Hay, who very kindly gave their services, while with marked generosity Messrs. Mowlem's tender was based on the cost price of the buildings.

It is hoped that they may be opened on June 25 on the occasion of the visit of the foreign guests of the Institution of Electrical Engineers. In view of this ceremony the invitations on March 16 were restricted to members of the board and their personal friends, the usual annual gathering of friends of the laboratory being postponed until June.

NOTES.

A preliminary programme has been received of the events in connection with the Franklin bi-centenary, which the American Philosophical Society will celebrate at Philadelphia on April 17–20. The opening ceremony will take place on April 17, when the president, Prof. Edgar F. Smith, will deliver an address. Numerous papers on subjects of science will be read on April 18 by distinguished American men of science. In addition to these, Sir George Darwin, K.C.B., F.R.S., will read a paper on the figure and stability of a liquid satellite, and Prof. Hugo de Vries, of Amsterdam, will deal with elementary species in agriculture. Addresses will be given during the evening of the same day by Prof. E. L. Nichols, on Franklin's researches in electricity, and Prof. E. Rutherford, F.R.S., on the modern theories of electricity and their relation to the Franklinian theory. On April 19 honorary degrees will be conferred by the University of Pennsylvania, and an oration will be delivered by the Hon. Hampton L. Carson, Attorney-General of Pennsylvania. Ceremonies will be performed on this day at the grave of Franklin. On April 20 addresses in commemoration of Franklin will be given by Dr. H. H. Furness, who will speak of him as citizen and philanthropist; Dr. C. W. Eliot will pronounce a eulogy of him as printer and philosopher; and Dr. J. H. Choate as statesman and diplomatist. The presentation of the Franklin medal to the Republic of France, in accordance with the Act of Congress, will be made by the Hon. Elihu Root, Secretary of State.

Dr. Libbertz, the scientific director of the bacteriological department of the Farbwerke, Hochst a. M., is going to South Africa with Dr. Robert Koch to study the question of sleeping sickness.

We learn from the *British Medical Journal* that the donations to the fund being collected for the establishment of an Institute of Cancer Research in connection with the University of Heidelberg now amount to 34,000*l.*

An exhibition devoted to engineering and mechanical appliances will be held at Olympia from September 15 to October 17. Sir William White, K.C.B., is president, and the list of patrons includes the presidents of the various engineering societies. The offices of the exhibition are at Balfour House, Finsbury Pavement, London.

The eighth International Agricultural Congress will be held in Vienna on May 21–25, 1907. The proceedings of the congress will be carried on in eleven sections, of which section ii. will be devoted to questions on instruction in agriculture and forestry, section vi. to agricultural industry, section vii. to the protection of plants, and section x. to vine growing, &c.

A Reuter telegram states that M. Mylius Erichsen's Danish expedition to the north-east coast of Greenland will leave Copenhagen at the end of June, and will proceed *viâ* the Færöe Islands and east Iceland to the east Greenland pack-ice, through which the explorer expects to be able to penetrate into East Greenland between 57° and 77° northern lat. In addition to the Danish members, the exploring party will probably include Dr. A. Wegener, from Germany, as physicist and meteorologist, and Dr. Baron Firchs, from Russia, as geologist.

According to a Reuter message from Peshawar, a letter from the Governor of Balakh states that while some peasants were preparing their land for cultivation they came upon some ruins, which on further examination proved to be wall enclosures of a ruined city. The Governor visited the spot, and found the ruins of a large city, with some gold coins, the inscriptions on which nobody could read. Old Afghans said they had heard from their ancestors that a large Kafir (or infidel) city existed in the vicinity, which had been destroyed long since, and that in the ruins were buried the treasure of the Kafir kings. Some of the coins were sent to the Ameer for inspection.

The Washington correspondent of the *Times* states that the report of the American members of the International Commission for the Preservation of the Niagara Falls recommends that legislation be passed, based on a treaty between America and Canada, to prevent further depletion of the water, to maintain the present scenic effects, and to regulate the electrical supply companies which are using the Falls for power. It is proposed to limit the diversion of the waters on the American side to 28,500 cubic feet a second, and the diversion on the Canadian side to 36,000 cubic feet. This advantage of Canada is in reality only on paper, as the power generated on the Canadian side is used largely in the United States. The report states that the diversion of water by works already authorised is likely to injure the Falls, and will possibly leave the American fall dry. It is estimated, however, that five-sixths of the total of 60,900 feet a second authorised chiefly affects the Canadian Horseshoe Falls.

Mr. Frank Stromsten gives a good account of the anatomy and development of the venous system of various species of turtles (*Amer. Journ. of Anatomy*, iv., 1905, p. 453). About forty turtles of the more common species were dissected, and fifty turtle embryos were studied for the development of the veins. In general, the development

of the veins of the hepatic and renal portal systems is the same in turtles as in lizards and snakes, but there are important differences.

SCIENCE BULLETIN No. 7 of the Brooklyn Institute contains an account by Mr. C. Schaeffer of beetles new to the United States, and also a description, by Dr. H. G. Dyar, of new moths from Arizona. Among the latter use is made of the generic name Janassa, usually applied to a group of Palæozoic fishes. The marine ostracod crustaceans of Vineyard Sound form the subject of a paper by Mr. J. A. Cushman in the Proceedings of the Boston (U.S.A.) Society of Natural History, vol. xxxii., No. 10.

THE results of a study of the wing-structure of the hymenopterous insects of the group Tenthredenoidea, published in No. 1438 of the Proceedings of the U.S. National Museum, have enabled Mr. A. D. MacGillivray to demonstrate the origin of the modern complex hymenopterous wing from one of the simplest type. Throughout the line of evolution all the modifications have tended to render the wing more efficient as an organ of flight, this efficiency being due to the arrangement of the veins in such a manner as to stiffen the areas subjected to the greatest strain.

IN the *Verhandlungen* of the German Zoological Society for 1905 Prof. Simroth discusses the geographical distribution of land-shells, salamanders, and ganoid fishes, more especially in connection with climatic changes due to precession of the equinoxes; while Dr. K. Guenther contributes a review of theories and facts bearing on bird-migration. Special interest attaches to an article by Dr. O. Abel on the phylogenetic evolution of the cetacean dentition and the systematic relations of the Physeteridæ. Both physeteroids and ziphioids are considered to have originated, independently, from squalodonts during the Miocene, while the latter are connected with the true Eocene zeuglodonts by means of Microzeuglodon. If this phylogeny be well founded, we may accept the descent of cetaceans from creodont carnivores.

AMONG the contents of part ii. of the third volume of the quarterly issue of the Smithsonian Miscellaneous Collections is a paper on the great whale-shark (*Rhinodon typicus*), by Mr. B. A. Bean, in which figures are given of the type specimen taken at the Cape in 1828, and of an individual recently stranded on the Florida coast. This shark is stated to grow to a length of 60 feet, and is thus the next largest animal to the biggest kinds of whales. Like its relative the northern basking shark, it has a terminal mouth and feeble dentition, and is quite harmless to man. In a second article Mr. W. H. Osgood describes remains of certain ancestral musk-oxen from Alaska and other parts of Arctic America, while in a third Mr. T. Gill furnishes a very interesting account of the carp group. In the course of a paper on Mexican land-shells, Dr. W. H. Dall describes a new genus, Hendersonia, remarkable for having developed a multispiral discoid shell, with an upturned mouth, quite unlike those of its relatives.

IN the Bulletin of the Johns Hopkins Hospital for February (xvii., No. 179) the biographical sketches of medical worthies of former times, which have formed a marked and interesting feature of recent issues, are continued, the subject of this month's sketch (by Dr. Walter Steiner) being the Rev. Gershom Bulkeley, of Connecticut, born about 1635, who, having served in the ministry, was obliged to resign owing to weakness of voice, and subsequently devoted himself to the practice of medicine. Articles of medical interest, reports of societies, &c., complete the number.

IN his presidential address to the Entomological Society of London, Mr. F. Merrifield surveyed the results obtained by other investigators and himself in studies of the influence of temperature and other conditions on insects. As a result of artificial experiments, it has been found that alteration of temperature on developing insects affects to some extent the colouring of the adults. Apparently high and low temperatures do respectively make the insects tend to approximate in colouring to warmer temperate and arctic types.

THE issue of the Philippine Journal of Science, the first number of which (January) has reached us, is further proof of the manner in which scientific research is being cultivated by the American Government. The journal is well printed on paper 10 inches by 7 inches, and contains several excellent illustrations. The editors are Dr. Paul Freer and Dr. Richard Strong and Mr. H. D. McCaskey, and the contents of the present number are three articles on the cocoa-nut palm and oil, by Dr. Freer, Mr. E. B. Copeland, and Mr. H. S. Walker respectively; the occurrence of *Schistosoma japonicum* vel. *Cattoi* (a parasite fluke) in the Philippines; and a study of some tropical ulcerations of the skin, by Dr. Strong.

PROF. ADAMI discusses in an interesting paper the question of the transference of bovine tuberculosis to man through milk (*Amer. Medicine*, ix., 1905, p. 683). He holds that such conveyance is not so frequent as is generally accepted (von Behring goes so far as to attribute most human tuberculosis to the use of tuberculous milk in infancy). Kitasato has recently published statistics of the incidence of tuberculosis in Japan, which show that the deaths from tuberculosis in Japan are just about in the same proportion to the total deaths and to the total population as are the deaths from this disease in European countries; but primary intestinal tuberculosis in the young (which has been attributed to the ingestion of tuberculous milk) is rather more prevalent (30 per cent. of the total) than in Europe and America (25 per cent.). The use of cows' milk for feeding infants is unknown in Japan, and Prof. Adami therefore holds that the facts gathered in Japan show that intestinal tuberculosis, which is as frequent there as in Europe, cannot be attributed to the ingestion of infected cows' milk, and cannot therefore be of bovine origin; and the inevitable conclusion is that if intestinal tuberculosis is moderately frequent, and not of bovine origin, then similarly a large proportion of European intestinal tuberculosis is in all probability not due to infection from milk.

TWO leaflets referring to British East Africa have been received; of these, leaflet No. 12 of the Department of Agriculture, Nairobi, provides a list of forage plants with their special characteristics, and leaflet No. 2, issued by the Forest Department, deals with native trees. The list of native trees, with vernacular names and uses, is accompanied by a few hints as to the selection of suitable species, the collection of seeds, and the methods of planting.

THE Kew Bulletin for the year 1900 (Nos. 178–180) reached us a few days ago! The Bulletin, which has been in abeyance since the volume for 1901 was completed—with the exception of a part issued as No. 1, 1905—was re-inaugurated with a part recently published as No. 1, 1906. This number is devoted entirely to descriptions of

new specimens, the contents being "Decades Kewenses, xxxvi.–xl.," "Diagnoses Africanæ, xiv.," and "New Orchids, Decade 26." The first furnishes a list of ferns and flowering plants, of which the majority were collected by Dr. Henry in China. An interesting species is *Cuscuta Upcraftii*, that has been grown on potatoes from seed collected in Tibet by Mr. W. M. Upcraft. A list of staffs in botanical departments at home, in India, and the colonies has also been published as Appendix iv., 1905.

AN interesting report on the mineral resources of the Kalahasti Zamindary, Madras, has been published by Mr. V. S. Sambasiva Iyer, of the Mysore Geological Department (Bangalore, 1906). Gold, iron ore, barytes, and marble are met with. The evidences obtained and the records of old workings fully justify a detailed prospecting of the Sirasinambedu gold deposits.

IN the *Engineering Magazine* for March there is an admirably illustrated account of gypsum mining in the vicinity of Paris by M. Jacques Boyer. Interesting details are given of the calcination of the material and of the preparation of plaster of Paris. At the present time some eighty companies are engaged in the industry near Paris, and 5500 workmen are employed.

A REMARKABLE example of the surface outcrop of an iron ore deposit is illustrated in an article on iron ore in Mexico, by Mr. R. H. Anderson, in the *Engineering and Mining Journal* of New York (vol. lxxxi., No. 9). The deposit is situated on the Las Truchas creek, near the boundary of the States of Michoacan and Guerrero. The outcrop is 10,000 feet in length and 4000 feet wide. It rises to a height of 450 feet.

THE paper on smoke prevention contributed by Mr. A. J. Martin to the conference on smoke abatement at Westminster in December, 1905, has now been published in pamphlet form (London: Sanitary Publishing Co., Ltd., price 1*s*.). Mr. Martin advocates a scheme of long-distance gas transmission, and urges that a strong permanent committee be appointed by the Government to deal with the evils produced by smoky fogs, and the desirability of providing a cheap, smokeless fuel for domestic and industrial use.

THE opening number of vol. iii. of the *Bollettino* of the Italian Meteorological Society contains an interesting article on the supposed connection between rainfall and volcanic activity, unsigned, but evidently emanating from the Observatory of Catania. The author finds that whether account is taken of the daily variation in the activity of Etna during the eruption of 1892, or the whole series of eruptions the date of which is known with accuracy, there is no evidence of any connection between the volcanic activity of Mount Etna and the local rainfall; neither of these determines or is determined by the other.

THE weather during the past week has been unusually cold and disagreeable over the whole of the British Islands, the day temperatures being about 10° below the average for fifty years, with sharp frost at night, and frequent showers of snow and hail. These conditions were produced by a complex distribution of barometric pressure, the chief features of which were an anticyclone lying over the Atlantic at some distance to the west of our shores, with areas of low pressure over Germany and the south-west of France, and they were consequently accompanied by bitter northerly and north-easterly winds, whilst gales were experienced on several coasts. The following low night screen temperatures have been reported to the Meteorological Office:—22° in the Midland counties and 23° in the south of England. At Greenwich the exposed thermometer fell to 18° on the morning of March 23. Sunshine exceeded the normal amount in several districts.

THE University of Innsbruck publishes in a concise and handy form the results of the observations made at its meteorological observatory, situated about 1886 feet above the sea. The last pamphlet received contains observations and mean results for 1902, taken three times a day, together with hourly values from various self-recording instruments. The tables have been prepared by Dr. W. Trabert, which is a sufficient guarantee for the accuracy of the work. There is a useful appendix by Mr. H. von Ficker on cloud formation in the Alpine valleys from observations extending from January, 1904, to March, 1905, with valuable notes on the occurrence and behaviour of the Föhn wind. This phenomenon is well known to Alpine observers as, generally speaking, a dry, warm wind, to the influence of which the melting of the snow in the spring is chiefly due.

THE current number of the *British Journal of Psychology* (vol. i., part iv.) contains as its main feature an article by Dr. W. H. R. Rivers entitled "Observations on the Senses of the Todas," a small and possibly degenerating community of about 800 individuals, living among the Nilgiri Hills in southern India. The methods of observation were similar to those used by the Cambridge expedition to the Torres Straits. Visual acuity, colour-vision, visual illusions, tactile discrimination, tactile illusions, sensibility to pain, smell, taste, hearing, were all made the subject of tests. Of these the most elaborately treated are visual illusions, particularly the illusion of compared horizontal and vertical lines, and Dr. Rivers puts the results obtained from the Todas in this department of observation alongside those obtained from Cambridge undergraduates. In his general conclusions he lays stress on the difference in the part played by inference in the process of determining the sensory threshold, and the consequent difficulty of comparing sense-acuity in races of different culture. This play of inference reaches its greatest scope in the case of smell. In visual acuity and the tactile acuity of the forearm it would appear that the Todas have a slighter degree of sensibility than more civilised races, but they are inferior rather than superior in acuity of smell, and probably in acuity of hearing; they are also less sensitive to pain. Among other articles are those of Dr. James Ward, "Is 'Black' a Sensation?" and of Mr. W. McDougall, on "The Illusion of the 'Fluttering Heart' and the Visual Functions of the Rods of the Retina." Mr. McDougall points out that two quite distinct illusory appearances have been hitherto confused and brought together under the designation "the fluttering heart," and he claims that the true explanation of one of these is to be found in a suggestion made by Prof. J. von Kries.

IN the *Chemiker Zeitung* for March 21 is an interesting report, by Dr. E. Gerlach, dealing with the advances made by electrotechnical industries during last year. The writer deals particularly with electrical illumination, telegraphy and telephony, new accumulators, dynamo machines, electrical heating, power transmission, electrical railways, conductors and insulators, and measuring instruments.

As is well known, the carbides of different metals yield different hydrocarbons when acted upon by water. Thus while calcium carbide gives acetylene, aluminium carbide

[pr]oduces marsh gas (methane). We learn from the *Zeitschrift fur Elektrochemie* (vol. xii., p. 20) that in St. Alban, France, a carbide is now being manufactured from which ethylene is evolved when it is acted upon by water. The ethylene so obtained is pumped into sulphuric acid, by which it is absorbed with production of ethyl hydrogen sulphate. Now when ethyl hydrogen sulphate is acted upon by water, alcohol and sulphuric acid are produced. By distillation the alcohol can be obtained free from the sulphuric acid, and the sulphuric acid can again be obtained in the concentrated condition by evaporation. Furthermore, the metallic oxide which is used in the production of the carbide is again obtained when the carbide is acted upon by water, so that the production of alcohol is summed up in the equation carbon + energy = alcohol. Up to the present it has been found necessary to use four times the quantity of carbon which should theoretically be required. How much more energy it is necessary to employ than is required by the theory is not stated. We remember that so far back as 1893, when the calcium carbide industry was in its infancy, it was suggested that the acetylene might by reduction with hydrogen be converted into ethylene, and the ethylene so obtained be employed for the manufacture of alcohol. In fact, we believe that several patents were taken out upon the subject. Owing to the difficulty of reducing acetylene, the process could hardly be expected to be a success. In the present case, however, provided the formation of the carbide is not too costly and the recovery of the sulphuric acid and metallic oxide not too expensive, the process seems to possess at any rate the elements of success.

THE first part has been received of an "Atlas of the World's Commerce," by Mr. J. G. Bartholomew, which is to be published by Messrs. George Newnes, Ltd., in twenty-two parts. The parts, which cost 6*d*. each net, are to appear fortnightly.

MR. DAVID NUTT has issued a ninth edition of the late Prof. A. Milnes Marshall's well known book on "The Frog: an Introduction to Anatomy, Histology, and Embryology." The work has been edited by Dr. F. W. Gamble, who has revised the chapter on development and added some figures.

A NEW monthly periodical, entitled *Science and Technology*, price sixpence net, has just appeared. It is intended to be of interest and assistance to teachers and students. The first number contains articles dealing with educational administration, examination syllabuses, and reports of meetings. The only contribution of a wholly scientific character is a reprint of Prof. S. P. Thompson's lecture at the Royal Institution on the electric production of nitrates from the atmosphere.

A THIRD edition of Sir William Ramsay's "Gases of the Atmosphere. The History of their Discovery," has been published by Messrs. Macmillan and Co., Ltd. The first edition of the book, published in 1896, included a non-technical description of argon, discovered in the atmosphere in 1894. To the second edition of 1900 a new chapter was added describing the other four inactive gases discovered to be present in air—helium, separated from the atmosphere in 1900, and neon, krypton, and xenon, discovered in 1898, and separated from argon and from each other during 1899 and 1900. The present edition has also been enlarged by the addition of another chapter, this one treating of the radio-active gases produced by the disintegration of radium and radium-thorium, which have been added recently to the list of constituents of the atmosphere.

OUR ASTRONOMICAL COLUMN.

COMET 1906*c*.—From observations made on March 19, 20, and 21, Dr. Strömgren has computed the following elements and ephemeris for the comet discovered by Mr. Ross on March 18:—

Elements.

$$T = 1906 \text{ Feb. } 22{\cdot}216 \text{ Berlin M.T.}$$

$$\left.\begin{aligned} \omega &= 281^\circ\ 24'{\cdot}1 \\ \Omega &= 73^\circ\ \ 2'{\cdot}1 \\ i &= 80^\circ\ 34'{\cdot}0 \end{aligned}\right\} 1906{\cdot}0$$

$$\log q = 9{\cdot}88336$$

Ephemeris 12h. M.T. Berlin.

1906	α (h. m. s.)	δ (° ′)	log Δ	Brightness
Mar. 29	2 38 33	+ 4 11·5	0·2356	0·63
April 2	2 48 40	+ 7 38·4	0·2547	0·53
6	2 58 9	+10 47 5	0·2732	0·44

(*Kiel Circular*, No. 87.)

OBSERVATION OF COMET 1905*c* AFTER PERIHELION.—A letter received from Prof. H. R. Morgan (Glasgow, U.S.A.) by Prof. Pickering states that the former observed Giacobini's comet, 1905*c*, on February 21, that is, since it appeared to the east of the sun.

The comet's apparent position at 7h. 40m. 44s. (Glasgow M.T.) was α = 1h. 8m. 29·2s., $\delta = -11^\circ\ 9'\ 11''$, which gave corrections of −11s. and $-3'{\cdot}4$ to Herr Wedemeyer's ephemeris on the date of observation (*Astronomische Nachrichten*, No. 4079).

NEW VARIABLE STARS IN THE REGION ABOUT γ SAGITTÆ.—From the comparison of several photographs taken with the Bruce telescope, Prof. Wolf has discovered fifty-five new variable stars in the region about γ Sagittæ.

In No. 4079 of the *Astronomische Nachrichten* he gives the details concerning the discovery and measurement of each star, and, in addition, a list showing the position (1855·0) and the magnitude on various dates between 1900·7 and 1905·7. Forty-seven circular charts which accompany the paper show the region immediately surrounding each variable.

THE SUPPOSED NEBULOSITY AROUND NOVA AQUILÆ NO. 2.—In the opinion of Prof. Frost, the suggestion that the nebulous appearance of images of Nova Aquilæ No. 2 is entirely due to chromatic aberration is the correct one.

Plates taken with the 24-inch *reflector* at Yerkes Observatory on September 21 and 27, and October 23, 1905, show no nebulosity, whilst Prof. Wolf has obtained similar effects to this apparent nebulosity with other stars having peculiar spectra. A third argument against the phenomenon being due to true nebulosity is that, in order to produce the image obtained, the intrinsic brightness would have to be at least 1800 times as bright, in proportion to the light of the star, as that of the nebula known to exist around Nova Persei (*Astronomische Nachrichten*, No. 4079).

SOME TESTS OF THE SNOW TELESCOPE.—A very interesting note by Prof. Hale, published in No. 1, vol. xxiii., of the *Astrophysical Journal*, describes the present condition, and some tests, of the large Snow telescope which has been erected at the Solar Observatory, Mount Wilson.

The greatest inconvenience encountered in the early use of this instrument was in connection with the spectroheliograph work. Three mirrors are employed, of which the first, the 30-inch cœlostat mirror, reflects the solar rays on to a 24-inch plane mirror, which in turn directs the beam on to the 24-inch concave mirror of 60-feet focus, which forms the image of the sun on the primary slit.

When the instrument was used, with a high sun, on a hot, windless day, it was found that a serious change of focus, amounting in some cases to 12 inches, occurred, and, worse still, the mirrors became distorted, giving a difference of focus for the opposite limbs of the image of as much as 3 inches.

On days when a cool breeze blew across the surface of the mirror the change was less, so arrangements have now been made to send a current of air across the face of each mirror between the exposures, by means of fans.

Prof. Hale has found that an hour after sunrise is the best time for solar work, and after that an hour before sunset.

Experiments are being carried out for the purpose of discovering some good substitute for glass in mirror making. "Invar" has proved to be too soft, and the fused quartz discs have not been a success. Prof. Hale suggests that speculum metal will be found to answer the purpose better than glass.

Photographs taken with the Snow telescope have proved better than those obtained with the 40-inch refractor at Yerkes, and Prof. Hale states that, from a mechanical standpoint also, the telescope has proved completely successful.

STUDIES ON THE SYNTHESIS OF PEPTIDES AND PROTEIDS.[1]

AMONG the many brilliant achievements in synthetic chemistry accomplished by Prof. Emil Fischer during the last quarter of a century, none have surpassed in interest the remarkable series of researches which formed the subject of a recent address to the German Chemical Society.

In reading this address it is impossible to say which commands greater admiration, the author's consummate skill and endless resource in sweeping aside each difficulty as it arose in a most intricate field of experimental inquiry, or his intense and ceaseless activity in producing almost month by month during the past five years a wealth of new knowledge of the very first importance to biological science.

"Whilst our cautious colleagues," says Prof. Fischer, "fear that a systematic study of this group of compounds (the proteids) will be beset with endless difficulties on account of their troublesome physical features, there are others, among whom I count myself, who are more optimistic, and hold that an attempt at least ought to be made with every modern appliance to lay siege to this unconquered citadel; for it is only by a bold attempt that the limitations of our present methods can be adequately gauged."

The success which has so far attended Prof. Fischer's first attack promises a speedy capitulation. The proteids will then be made to deliver up the key to their molecular structure, and the first real advance in biochemistry will have been accomplished.

Although physiological chemistry has done much in the past in the way of classifying the numerous members of the proteid group, in preparing a few members in the crystalline form, in attaching to different individuals different biological functions, and in ascertaining the fundamental changes effected by ferment action, our knowledge of their chemical constitution has up to the present been extremely meagre. Apart from the percentage composition, it is limited mainly to the results of hydrolysis by acids, alkalis, or digestive ferments. When submitted to these agents all proteids yield successively albumoses, peptones, and, finally, amino-acids. Of the nature of the first two we are but little better informed than of that of the proteids themselves.

The study of the amino-acids has been attended with more success, for not only has the structure of the majority of them been ascertained, but many have been prepared synthetically. The following is a list of amino-acids obtained by hydrolysing one or other of the natural proteids:—

Glycine	Serine (α-amino-β-hydroxy-propionic acid)
Alanine	Tyrosine
Aminovaleric acid	Tryptophane (skatolamino-acetic acid)
Leucine	Lysine
Isoleucine	Arginine
Phenylalanine	Histidine
Glutamic acid	Diaminotrihydroxydodecanic acid
Aspartic acid	Diaminoglutaric acid
Cysteine	Diaminoadipic acid
α-Pyrrolidine carboxylic acid (proline)	Hydroxyaminosuccinic acid
Hydroxy-pyrrolidine carboxylic acid (oxypyroline)	Dihydroxyaminosuberic acid

[1] *Vide* Address by Prof. Emil Fischer, "Untersuchungen über Aminosäuren Polypeptide und Proteine" (*Berichte der deutschen Chem. Gesell.*, 1906, xxxix., 530.)

It was to the study of these acids—the fragments, so to speak, of the albumin molecule—that Fischer first directed his attention, hoping ultimately by piecing them together to construct the simplest of the albumins. In the synthesis of the monoamino-acids Fischer has added to the methods already known that of brominating the alkyl malonic esters and then converting the corresponding acid into the α-bromo-fatty acid, which with ammonia yields the amino-acid. He has, moreover, devised an ingenious process for resolving the synthetic, and, consequently, inactive compounds into their active components. The amino-acids are such weak acids that they refuse to form crystalline salts with the active alkaloids. By converting them into the benzoyl or formyl derivatives, strong acids are produced which may be easily resolved by the ordinary process of fractionally crystallising the salts of the active bases. The diamino-acids, such as ornithine (αδ-diaminovaleric acid) and lysine (αε-diaminocaproic acid), both common products (the former as arginine) of proteid hydrolysis, have also been synthesised by Fischer by adapting Gabriel's reaction in one case and that of Blank in the other. Gabriel's phthalimidopropylmalonic ester, when brominated, gives a monobromo-derivative, which is then hydrolysed and heated to remove one carboxyl group, the resulting compound being phthalimidobromovaleric acid,

$$C_6H_4\begin{matrix}CO\\CO\end{matrix}N.CH_2.CH_2.CH_2\,CHBr.COOH.$$

This was converted into the amino-derivative, and by splitting off the phthalyl radical the racemic form of natural ornithine was obtained,

$$NH_2.CH_2.CH_2.CH_2.CH(NH_2).COOH.$$

The starting point for the preparation of lysine was Blank's γ-cyanopropylmalonic ester,

$$CN.CH_2.CH_2.CH_2.CH(COOC_2H_5)_2,$$

which is converted by nitrous acid into α-oximino-δ-cyanovaleric ester,

$$CN.CH_2.CH_2.CH_2C(:NOH).COOC_2H_5.$$

The latter, on reduction, yields the racemic form of lysine (αε-diaminocaproic acid). The synthesis of hydroxyamino-acids such as serine of silk fibroin has also been accomplished by applying Strecker's reaction to the hydroxy-aldehydes. Thus ammonia converts the cyanhydrin of glycollic aldehyde into the aminocyanhydrin which on hydrolysis yields inactive serine,

$$CH_2(OH).CHO \longrightarrow CH_2(OH).CH(OH).CN \longrightarrow$$
$$CH_2(OH).CHNH_2.CN \longrightarrow CH_2(OH)\,CHNH_2.COOH.$$

Of no less importance to the solution of the albumin problem have been the new methods furnished by Fischer for the separation and identification of the products of proteid hydrolysis, for a correct knowledge of the varied compounds which compose the albumin molecule must necessarily precede any attempt to effect its synthesis. Foremost among these stands the "ester method." It consists in converting the mixture of amino-acids, obtained on hydrolysis, into the corresponding esters, which are then submitted to fractional distillation under very much reduced pressure (10–15 mm.). The method cannot, however, be conveniently applied to the separation of tyrosine or the diamino-acids, which are treated in a different fashion. Space does not permit of more than a passing reference to the formation of benzoyl, formyl, and β-naphthalene sulphonyl derivatives, and of the phenyl hydantoins obtained with phenylisocyanate, all of which have been utilised either in the purification or identification of the amino-acids. We must leave this part of the subject in order to follow Prof. Fischer into the more attractive field of constructive research, and examine the plans which he has laid for attacking the synthetic side of the problem. Simply stated, the object he has had in view has been to link together two, three, four, or more molecules of those amino-acids which the proteids yield on hydrolysis, and by varying the combinations to obtain eventually something resembling the peptones or the simplest albumins. To these artificial combinations of

amino-acids Fischer has given the name of *polypeptide*, or, according to the number of single amino-acid groups present, di-, tri-, tetra-, &c., peptide. This view of the constitution of proteid matter, which seemed at the outset of the investigation warranted by the nature of the evidence then forthcoming, received ample justification by the very recent isolation of the first natural dipeptide in the process of hydrolysing silk fibroin. But we are anticipating matters. The first of the polypeptides was obtained by Curtius in 1882, but as its structure is complex and has only been lately ascertained, we will begin with the simpler members prepared by Fischer.

In 1901 Fischer and Fourneau found that glycine anhydride, which, according to Curtius, is formed when glycine ester is heated in aqueous solution, is partly hydrolysed with mineral acids into glycylglycine, the first and simplest of the dipeptides,

$$NH\left\langle\begin{matrix}CH_2.CO\\CO.CH_2\end{matrix}\right\rangle NH + H_2O = NH_2.CH_2.CO.NH.CH_2.COOH.$$

A year later Fischer found that a third amino-acid or peptide group could be linked to the carbethoxy-derivative of glycylglycine (prepared by the action of chloroformic ester on the dipeptide) by heating it with leucine ester, whereby carbethoxyglycylglycyl-leucine ester resulted, which on hydrolysis is converted into the free acid,

$$C_2H_5CO_2.NH.CH_2.CO.NH.CH_2.CO.NH\ CH(C_4H_9)CO_2H.$$

The next year saw the introduction of a new method for adding fresh links to the peptide chain by the use of thionyl chloride. This effects the conversion of the end carboxyl group into the acid chloride, and it thus became possible by the subsequent action of an amino-ester to add a new peptide group to the molecule. Thus carbethoxyglycylglycine was converted successively into the acid chloride, and then by the action of glycine ester into carbethoxydiglycylglycine ester, and by a repetition of the process into carbethoxytriglycylglycine ester. Similar compounds with different amino-acids were obtained by this reaction. In all of them, however, the carbethoxy-group at the amino end of the chain refused to be removed, and a new method had to be found for preparing the free polypeptides. This was soon forthcoming. In 1903 Fischer and Otto introduced the chloracyl chlorides for the purpose. Glycylglycine ester was first combined with chloracetyl chloride, hydrolysed, and warmed with ammonia, whereby diglycylglycine was formed,

$$ClCH_2.COCl + NH_2.CH_2.CO,NH.CH_2.COOR = ClCH_2.CO,NH.CH_2.CO,NH.CH_2.COOR + HCl.$$

$$ClCH_2.CO,NH.CH_2.CO,NH.CH_2.COOH + NH_3 = NH_2\ CH_2.CO,NH.CH_2.CO,NH.CH_2COOH + HCl.$$

This method proved extremely fruitful, and led to the production of a variety of di-, tri-, tetra-, and penta-peptides.

It will be easily conceived how the methods just described afford the means of lengthening the peptide chain at either end. In the one case an α-chloro- or bromo-acyl chloride is added to the amino-group at one end, or, at the other, the carboxyl group is converted into the acid chloride, for which purpose thionyl chloride has since been replaced by phosphorus pentachloride dissolved in acetyl chloride. In the first case the action of ammonia, in the second that of an amino-acid or another peptide (the ester is not necessary) in presence of alkali, produces the new peptide. By combining the two processes, hexa- and hepta-peptides giving the biuret reaction have been formed from diglycylglycine, and Prof. Fischer confidently predicts the synthesis of still longer chains. In the present year Fischer has also found that two molecules of the methyl ester of diglycylglycine can by heating be combined into the ester of pentaglycylglycine, which yields the hexa-peptide on hydrolysis.

If the proteids themselves and the amino-acids to which they give rise comprised optically inactive members, the experimental difficulties in the way of synthesis might be looked upon as approaching solution; but few of the natural products are inactive, and the question of preparing by artificial means active polypeptides must be faced. This part of the problem has not been neglected. By resolving the amino-acids into their active constituents before linking them together, or by submitting certain inactive members to the selective fermentation of pancreatic juice (for trypsin acts upon some of the polypeptides as it does on proteids), active polypeptides have been obtained.

In addition to the action of trypsin, the polypeptides exhibit many characteristics of the simpler proteids; they are for the most part soluble in water; especially is this the case where the peptide is composed of different amino-acids; they are insoluble in alcohol, and many of the higher members give the "biuret" reaction. Like the proteids, also, they are quickly and completely hydrolysed by strong hydrochloric acid into amino-acids; the action of dilute hydrochloric acid and caustic alkalis is, on the other hand, very slow.

The concluding sections of the address will appeal more especially to physiologists, for they deal with the products of hydrolysis of the proteids themselves. Space will not permit of more than a passing reference to them; the reader who is interested in the products obtained by the action of pancreatic juice or the combined action of pepsin, hydrochloric acid, and pancreatin must refer to the original memoir. It may, however, be stated that pancreatin yields, in addition to numerous monoamino-acids, a product which does not give the biuret reaction, but shows a certain resemblance to the artificial polypeptides, and breaks up on hydrolysis with acids into alanine, leucine, glutamic and aspartic acid, as well as proline and phenylalanine. By the successive pepsin and pancreatin digestion the amount of this polypeptide body is diminished, but in its place proline and phenylalanine appear.

As many of the commoner forms of proteid matter behave in this way, Fischer concludes that proline is an actual constituent of the proteid molecule. For similar reasons he includes tyrosine, leucine, alanine, tryptophane, &c., which always appear in the pancreatic digestion of albumin, a view which is supported by the action of pancreatic juice on the artificial polypeptides containing these groups. But of all the facts which point to the polypeptide nature of the albumins, the most convincing is Fischer and Abderhalden's latest discovery of a dipeptide in silk fibroin, which they have identified as glycyl-*d*-alanine. The method of preparation is interesting, because it introduces the new principle of combining acid with pancreatic hydrolysis. The silk fibroin is first digested with 70 per cent. sulphuric acid for several days at 18°, then diluted with water, the acid removed with baryta, and the liquid evaporated and submitted to the action of pancreatic juice for eight days. The tyrosine which had then separated was removed, and the esters of the amino-acids were formed in the usual way and heated under reduced pressure at 65° to remove the alcohol and a little glycine and alanine ester.

From the syrupy residue dissolved in alcohol and saturated with ammonia gas (to convert the dipeptide ester into the diketopiperazine), a crystalline precipitate of glycyl alanine anhydride slowly separated. Fischer sees in this discovery a near prospect of obtaining the most important constituents of the natural peptones, and even of the albumoses, and of reproducing them artificially. "But the problem of reproducing true albumins," says Fischer, "is of far greater difficulty, for their reconstruction from the first products of hydrolysis (peptones and albumoses) will require entirely novel methods, and when these are found their application will probably be a laborious process. One may therefore ask the question whether the eventual success will compensate for the labour expended. This depends, in my opinion, on the profit which biological research can derive from it, and this, again, on the manner in which the synthesis has been accomplished. For such a synthesis may be compared to a tourist who rushes through a country in an express train and sees nothing. It is otherwise if the synthesis is constrained to advance slowly and to construct the molecule step by step. It is then like a traveller journeying on foot, who notes every feature of the road, and tries each side-path before the right one is found. He not only learns every inch of the country, but understands the nature of its inhabitants. He knows his way and can direct others. I can only look

upon it, therefore, as a piece of good fortune that synthesis demands the creation of countless new methods of construction, separation, and recognition, and the study of hundreds of intermediate products before the proteids themselves can be reached. For these methods not only serve in the end to produce all the natural albumins, but bring to light many more which may eventually serve to explain the remarkable changes which certain proteids effect in the form of ferments and toxins. J. B. C.

THE PROTECTION OF BIRDS.

IN its report for 1905, the Royal Society for the Protection of Birds directs attention to the circumstance that the year under review is the first during which it has enjoyed the privilege of a Royal Charter. Reference is also made to the importance of last year's ornithological congress in connection with the recognition of the great principle that bird-protection is an international affair, and that, in the case of migratory species, it is of little use to adopt protective measures in this country if indiscriminate slaughter is carried on abroad. It is, moreover, also pointed out that we are by no means free from reproach in this matter even at home, as is exemplified by the instance of a honey-buzzard which was killed and mounted in the Isle of Wight, although such procedure would have been illegal in Hampshire. The progress of bird-protection in India is referred to with approval; but it is stated that further international action is required in connection with the trade in "osprey-plumes."

Simultaneously with the report of the English Society for the Protection of Birds, we received those of the kindred American body, the National Association of Audubon Societies, for 1904 and 1905. The former of these contains a history of the "Audubon movement" in the United States by Mr. W. Datcher, the president of the association, and also the results of a special effort for the protection of water-birds, made possible by a fund at the disposal of the association. In the report for 1905 the president has to congratulate the association on its first year's working as a corporate organisation, the incorporation having largely augmented its power for good. After referring to the cordial relations existing between the association and foreign bodies the work of which is of a similar nature, the president directs special attention to correspondence relating to the urgent need of protection for the extensive bird-colonies in certain islands in the Pacific. Special efforts are being made to enlist the interest of the general public in bird-protection by means of exquisitely illustrated leaflets (of which we have received a sheaf) descriptive of some of the rare and more interesting birds. In the case of the cardinal and so-called American goldfinch, the illustrations are coloured.

THE PLACE OF POLYTECHNICS IN EDUCATION.[1]

THOSE of you who know what you are doing here and know what is being done in other places must feel that we are at a very interesting, almost a critical, time from an educational point of view. We may be said, indeed, to be at the beginning of a new renaissance—a new birth of learning, just in the same way that our forbears, A.D. 1000 up to A.D. 1200, were in the forefront of that first renaissance. But the trouble is that the dark ages did not cease then, for we have had a dark age since, and it is to correct this second dark age that this new birth is necessary. Now what did the inhabitants of Europe do at that first renaissance? They kept on the schools which had been brought down by the different rulers, the different church authorities, from the time of the Roman Empire. The Roman schools, judging from what the Romans did from Scotland to the south end of the Red Sea, must have dealt with the science of the time, and that perhaps is the reason that the earliest universities always included "the nature of things" in their curricula. A modern public schoolmaster might not think their education complete because Latin and Greek were the modern languages then, and the students were taught no dead ones; but, be this as it may, at the renaissance they insisted upon the teaching of Latin, because then everybody who was anybody spoke Latin—it was the *lingua franca* of Europe—and not to speak Latin was to belong to the corps of the deaf and dumb. Secondly, they had to learn Greek, because the movers in the educational world at that time were chiefly doctors, and they had learned all they could about doctoring and surgery from bad Latin translations of bad Arabic translations of the Greek authorities, so that when the Greek manuscripts became available all the world was agog to learn Greek in order chiefly that they might learn medicine and surgery. Now, I want to point out to you that in this we had education founded absolutely and completely upon the crying needs of the time. Very good. Then if we are going to do anything like that in our new renaissance, what ought we to do if we are to follow precedent? We must arrange our education in some way in relation to the crying needs of the time. The least little dip into the history of the old universities will prick the bubble of classical education as it is presented to us to-day. Latin was not learned because it had the most magnificent grammar of known languages. Greek was not learned in consequence of the transcendental sublimity of ancient Greek civilisation. Both these things were learned because people had to learn them to get their daily bread, either as theologians or doctors or lawyers, and while they learned them the "nature of things" was not forgotten.

Now what is the problem of to-day? We are in a world which has been entirely changed by the advent of modern science, modern nations, and modern industries, and it is therefore perfectly obvious that if we wish to do the best for our education it must be in some relation to those three great changes which have come on the world since the old days. Remember, in the old days there was no experimental philosophy, there was no steam, there was little relation practically between the ordinary lives of the people and the phenomena, or, at all events, the working of the world of nature around them. But with us all our life, the poorest life, the richest life, the country life, the town life, if it is to be lived properly and wholesomely, has to be lived in the full light of modern science; we have to know exactly the best thing to do and why we should do it. The problem before us to-day, if it be the same problem that was before those old peoples, the problem, that is to say, of learning everything we can from those around us in other nations, must drive us to the study of modern languages, just as the modern world conditions drive us to modern science, so that there, I think, we have an answer to those who may ask of us: What changes are you going to make in modern education if you are going to have the best possible education? First of all, we have the fact that we are bound, if we follow precedent, to deal with those things which are of importance from the present point of view. Latin is no longer the *lingua franca* of Europe, and we have better guides in science and philosophy than Aristotle. A question which arises when we go on to consider this matter is a very simple one: Is it worth while bothering about education? Is it worth while troubling to inquire what the old renaissance did or the new renaissance ought to do? Now there we approach a question in which the world is certainly very much wiser than it was a few years ago. Thirty or forty years ago, I am sorry to say, in this country practically nobody cared anything whatever about education, at all events about the education of the people, and the trouble with us now—the trouble that we shall have to take years to get over—is that in Germany that question was settled as early as the time of Luther, who insisted that it was the duty of all communities to look after the education of their children as well as the building of bridges and the making of roads. Now I think it is generally accepted, both in this country and in others, that whether the citizens of a State are educated or not is a matter of absolutely supreme importance, and when I say "educated" I mean educated morally and physically as well as intellectually. It is no longer merely the concern of the child or of the child's parent. It is acknowledged to be the only true foundation for a

[1] Extracts from an Address delivered at the Borough Polytechnic Institute on December 4, 1905, by Sir Norman Lockyer, K.C.B., F.R.S.

State's welfare and continued progress under conditions of peace or under conditions of war. We must face the applications of all the new sciences to every department of our much more complex national life, from the lowest employment to the highest fields of statecraft. If this is anything like true we have a great responsibility cast upon us when we talk about education. And when we inquire into the conditions we are still more impressed by this strenuous necessity of looking the facts in the face and seeing how this question affects us, not merely as being in this Borough Polytechnic, but as being Britons, as being members of a civilised community in the twentieth century. I have already said that even so far back as the time of Luther the Germans insisted that all their children should be educated; there should be no difference between the rich and the poor. What has grown out of that? The thing has gone on from strength to strength, until now in Germany, to deal with the Old World, we find a country with the greatest number of universities, with the greatest possible desire, from the Kaiser down to the peasant, to do everything for Germany that can be done by educating every child that is born in the country. What did democracy do when it had fair play in the United States of America? The first thing done was to apportion millions of acres for the future endowment of education. The acres did not mean much capitalised then, but they mean a great deal capitalised now; so that in the western States of America, where you get the purest voiced democracy that you can get, I think, on the surface of the planet, the children of the citizens, boys and girls, are educated from the age of six to the age of six-and-twenty without any call upon the parents or without any hesitation to carry as many as possible up to the very highest form of education. And when does the technical instruction come in there? The technical instruction is given only to those who have taken degrees in the university. Japan is following on the same lines. The educational system of Japan was started as near as may be at the same time that the new educational policy was begun here. The result of it has been that you have in Japan now a completely trained nation, trained to think, trained to do the best along any line that may turn up, and the difference between the existence of such a training and its opposite we have now in comparing the present condition of Japan with the present condition of China. Japan has become a world Power with whom we are proud to associate simply because the Japanese children have been taught to think and to do for thirty years. That is one of the most blessed things to think of, because it shows that if any nation, even the British nation, ultimately finds that it is backward, some thirty years, or perhaps even twenty years, spent in Japanese fashion may put everything right. But if that is so, then it is my duty to point out to you that we have a great deal to do. I have said that our present system of education was commenced, roughly, some thirty years ago, when the Japanese system was started, but at present our system deals only with primary and secondary education. It is a most extraordinary thing that our Minister of Education has not anything to do with the most important part of education. It is a situation truly British. Well, if we find that it is necessary to imitate the action of other States in having a department which shall include the top of education as well as the bottom, it is right that I should tell you at once that this will cost a great deal of money above what we spend at present. If we take one German university, Berlin—the equivalent of the University of London—the German State spends on it the sum of 169,000*l*. a year. That is to say, it spent that sum in the year 1891–2; whereas for our higher educational institutions—all the universities and university colleges in England, Ireland, Scotland, and Wales—until quite recently, the British Government allowed a smaller sum. That, I suppose, perhaps may be considered a fair estimate of the importance of education in the eyes of the British Government and in the eyes of the German Government. The worst of all this is that it is not merely a question of money and increasing taxation; it is a question of the hampering of all the industries of the country from top to bottom, from John O'Groat's to Land's End. In an official document published by the United States Government some four years ago, it was stated, as a result of considerable inquiry, that, taking the day students in the United States, in those colleges and universities where only day students were considered, there were more teachers of science in the United States than there were students of science turned out from the English colleges. Now, if that or anything like it is true, do you think that in any continued competition along any line in connection with any industry in the United States and here, we are likely to come out top? It is absolutely impossible. Sir William Mather, more recently, has given us some information on this point. He spent four months in America looking up the technical colleges and the conditions relating to the education of the industrial classes. He found that ten years ago there were attending educational establishments, that is to say, universities and colleges, 32,000 day students; all these were taking a three years' course. To-day there are 65,000 students being educated at these same colleges, and he says the spirit of America is so completely aroused to the necessity of making science the basis of all industry, it does not matter whichever it is, however simple the undertaking, that the whole tendency and trend of thought and feeling is to educate large masses of their young men so that they may take their part, not only as managers, employers, and capitalists, but as foremen and chief workmen in their great industries; and he ends by saying that it is necessary that we should urge our Government, whether it be Liberal or Conservative, to take care that there should be sufficient expenditure provided to enable our young people throughout the length and breadth of the land to possess equal advantages to those of young people of Germany and America.

If it is right that there should be this education, conferring upon the nation these enormous advantages, in considering the thing from the point of view either of the child or the child's parent, should there be one State-aided education for the rich and another for the poor? That is to say, if education—the *best* education—is worth all that is claimed for it, should the State deliberately foster the artificial production of a breed of second-rates? How can every child have a fair chance? Some of the older ones among you may remember Kingsley's "Saint's Tragedy." I will just quote two verses, with a little alteration in one:—

> "The same piece of clay makes a tile,
>   A pitcher, a taw, or a brick;
> Dan Horace knew life—you may cut out a saint
>   Or a bench from the self-same stick.
>
> "We fall on our legs in this world,
>   Blind kittens tossed in neck and heels;
> 'Tis education that licks Nature's cubs into shape,
>   She's the mill-head if we are the wheels."

Surely, then, if we must not differentiate education, if we must not knowingly support second-rate education, our duty is to find the best. We come, then, to the problem which I have not the courage to bring before you now, because one might talk for a week about it, and I have only twenty minutes left, even if you will grant me as much as that.

What is the best education? It has taken the world a long time to find out what it already knows about it, but I doubt whether even now the world has quite got to the bottom of the problem. I think we may begin by saying that the best education should teach us to learn how to think, how to observe and how to use our hands, eyes and brain; how to exercise the body, how to become good and useful citizens, and—this is my own notion, perhaps you all will not agree with it—how to bear arms. If you have such an education as that going on all over the United Kingdom, my idea is that, whatever may happen to them afterwards, whether the children become archbishops or ploughmen, they would not be harmed by such an education, and, as a matter of fact, they could not have spent their time better. Now that is a very important thing to bear in mind, because there are systems of so-called education about which it could be shown in a moment that those who have been put under them might have spent their time very much better. We must discriminate really very much more carefully than is generally done between education, which I will define as the power of learning how to think, and instruction, which means

the accumulation of facts. Education may bring us into contact with doing things by which money may be earned, but that contact in education is used for mental training. Useful knowledge may easily become the bane of education. Instruction in doing things frankly pursued for the purpose of earning a living is generally not so imparted that the power of thinking properly is increased and the general training carried on further. If that is anything like true, we come to the important consideration that the best teaching must certainly include the teaching of doing things—we must not merely cultivate the memory—and, above all, we must not stuff useful knowledge or anything else into those young minds with which we have to deal. They are not Strassburg geese; and the more you attempt to stuff them the worse it will be. What we have to do is to train the mind as a delicate rapier, enabling it to do anything it has to do in the most perfect manner—to train the eye, the hands, the brain to face anything under the best possible conditions. The question here arises, What sort of a Code have we now for the education of the young?—this new Code—the Code for the year 1905 for elementary schools. Well, for myself, I thank God that we have such a document. It is an enormous improvement upon everything, upon anything, which has gone before it in our country. I remember some twenty years ago, when the only concession made to the new knowledge was that some candidate, if he liked, might say something of what he knew about the common pump; it hardly went further than the common pump, but the new Code goes very much further than the common pump, and you may even look at the stars if you like; you may even observe once or twice a year where the sun is or where the moon rises. Having this official education for the young, how are we to deal with it in relation to such an institution as yours? How are we to consider what should happen to the young minds of boys and girls going up that educational ladder which Huxley pictured to us some years ago—that educational ladder from the gutter to the university? In considering such a ladder as this, of course the end of the teaching, the end of the time spent, in the primary school constitutes the first rung at which the educational ladder may be left, and you have to consider the certain number of boys and girls unfortunately getting off the educational ladder when they leave the elementary school. The question arises, Must everybody when they leave the primary school, and that, I am thankful to say, at a gradually increasing age; when they have done with the official, with the complete education, must they have done with the instruction which will enable them better to earn their daily bread—the instruction which should, if possible, be placed before them, because really it is to tackle that instruction and to tackle the life connected with it that they have been taught to think? If you omit to give a higher education, or education combined with instruction, to your boys and girls after you have taught them to think, you have made a good deal of that education ridiculous. Your institute proves that it is much better to give instruction to the young in things that they have to do before you make them absolutely face the music in the real contact with the stern world of reality, which they will certainly have to face sooner or later. When you consider, therefore, the stepping-off places from the education ladder—I have just referred to the first—and the necessity of getting instruction, of putting instruction in the way of those who have to step off the educational ladder, the importance, the enormous importance, of such an institution as yours begins to force itself upon one. Take the child in an elementary school under the present regulations. Instead of going on to the secondary school and continuing still further up the educational ladder, it can go to a higher elementary school. That is a new idea in England, and it is a very admirable one. When you ask, Why does the child step off? you will find yourself confronted chiefly with the dearness of education in this country, and then with the supposed necessity for early employment.

With regard to those two questions, I would just like to tell you a little story. I had, some thirty years ago, to visit Holland on an official mission, and among others I saw the Minister of Public Instruction there, who was a great friend of Prof. Reike, to whom I was accredited, and he told me what they had been doing then in Holland for the last six or seven years; precisely this same thing that the Board of Education is now doing with regard to the higher elementary schools. The boys left the elementary schools generally at the age of fourteen, and the habit was for those little creatures to be sent at once to the offices and counting-houses of the merchants in Rotterdam and Amsterdam and other places to begin their work as clerks, and the Minister told me, with a twinkle in his eye, that these shops and counting-houses were most extraordinary places, because they were full of high stools. The Minister thought he could not proceed with this suggested change of the continuation school, which was called the higher town school, until he could get the sympathy of those various merchants, and he went round and asked them whether, if he could prepare boys up to the age of seventeen years, they would make a trial of them. They said they would. I visited Holland some four or five years after this had taken place, and the Minister told me that if I went to Rotterdam or Amsterdam I should no longer find any of those tall stools. He said:—"Seventeen-year-old boys are there, and they will have none others; the time for the use of the boy of fourteen in a merchant's office in Holland has passed away; the boys who begin to do their work after they have been taught to think up to seventeen are so much better." There is just another story touching another point I will say a word about later. The Minister was so interested with this, and was so satisfied and delighted at the satisfaction which those boys gave to their employers, that he thought he would go a step further. I should tell you that the boys who continued in school after fourteen up to the age of seventeen were chiefly taught science and Latin, and he was anxious to know what would happen in the case of a competition between these boys and those from the gymnasia, which are the equivalents of our higher grammar or public schools in this country. The boys from the gymnasia went, in the natural course, when they left the gymnasia, to the university. So he obtained permission from the Government to give the high town school boys an extra year. Now, what did they have to do in this extra year? They had learned Latin, and they had learned science from the age of fourteen in their continuation school; all they had to do was to learn Greek. It seemed an impossible thing for the town schoolboys to attempt to learn as much Greek in nine months, which was the school year, as the boys in the gymnasia, who had been accumulating during nine years their instruction in the gymnasia and the primary schools; but, as a matter of fact, when the test leaving examination came to be gone through, the boys from the higher town school romped in over the gymnasia boys. So you see my story shows that the university is not an absolutely prohibited thing if those who have to do with the boys and girls concerned are keen enough to take every advantage of every opportunity; and it shows also that employers of labour, at all events in other countries, and I expect in this, will see the advantage of getting supplied with clerks and other assistants who have been taught to think as opposed to getting their offices crowded with people who have still to learn how to think.

There are several other questions connected with the Huxley educational ladder. One is that in leaving each rung we have frankly to acknowledge that we have to face the music of the struggle for existence. Not every boy who enters a primary school can go, of course, to the university, can go perhaps higher than a secondary school; some will even fail to get to a secondary school, but what you have to consider, I think, generally in relation to institutions like this is that if there is to be any stepping off the ladder the change must be made in the best possible way. The present system of allowing these changes from rung to rung to take place by examination by outsiders is, I think, absolutely and completely indefensible. I would hold the teachers in every primary school absolutely responsible for saying that such and such of their students will benefit by secondary education and some of their students will not, and if that be done, then, in consequence of the recent action of the London County Council,

it seems to me that you will have a rapidly increasing number of the best English boys and girls going on with their pure education, certainly well into the secondary stage. In this way you will catch your potential Faradays. One of the delightful things I found in my inspection here with Mr. Millis was that in your instruction, frankly so called, you make it as educational as you can, so that those who come to you after the age of the primary school may, if they so choose, by taking advantage of one or other of your organisations, not only get an immense amount of absolutely needed instruction for various walks of life, but an education which will be practically as good as an education which could be got on the ordinary education ladder to enable them to enter the universities. The recent improvements in education are brought home to us by the fact that Huxley's ladder by itself no longer represents all the present possibilities. There are now platforms at the chief stepping-off places, and ladders from them also leading to the university for those who do not fear to climb. These platforms are technical schools and institutes, in which practical training in science laboratories and literature must both find place.

There is one word I should like to say with regard to your day school. It is called a "Technical Day School for Boys." I find that in the London County Council list, Appendix B, it is called a "secondary school." Now are you a secondary school? That is a point that I am not quite familiar with. What I understand is that under the new regulations a school to be a secondary school must make application to the Board of Education to be reckoned as such, and if it is accepted you have this enormous advantage, or will have very shortly, if you have not it now. Your students will have the right to go to the university by passing the leaving examination, which will ultimately be carried on by the teachers in the secondary school, or, at all events, with teachers associated with the secondary school. I think you will agree with me that the less any education in any locality is fettered by examination by outsiders the better for that education it will be. If you are a secondary school your students will be able, as a matter of course, to enter the new university. Thank God that in London, after centuries of the neglect of education, we have a university; we shall soon be as well off as a good many second-rate towns on the other side of the water have been for hundreds of years. I believe it is settled that your students can matriculate at the university, can become internal students without the bugbear of Latin, if you look upon Latin as a bugbear. Personally, I do not; if you have time to learn Latin, so much the better, but if the struggle for existence is so great that it is science or nothing with you, well, with science you can now enter the London University from a secondary school. You will then carry your local students right up to the second rung, some will go on to the university, and some will step off to your evening classes. Voltaire, talking about education, said :—"On étudie les livres en attendant qu'on étudie les hommes" ("We study books before we have a chance of studying men"). Well, we have got past that now; we not only study books, but we study things, but whether we study books or things our education will not be complete until we study men, that is to say, until we have varied occasions of mingling with others who are thinking about other things, so that we may exchange thoughts and ideas and sympathies with other students of different branches of knowledge. Now I want to point out what a magnificent opportunity you have here for that kind of collegiate education. You are practically a college, and I believe strongly that this collegiate life, as we may call it, this mixing with one's fellow men, is of the very highest quality, that it is the absolute essential of a complete course of education which should produce what is called character. And let me remind you that people are prepared to pay a great deal for character. I find, for instance, that Mr. Balfour not very long ago said the collective effect of our public school education on character could not be over-rated, but he thought the boys of seventeen or eighteen who are educated in them do not care a farthing about the world they live in except so far as it concerned the cricket field, the football field, or the river. You have the machinery to enable you to care a great deal about the world you live in, to know an immense deal about it, and you have also the machinery for this formation of character. Now I believe in the combination, and it is upon that ground I hope some future day to see a strong secondary school here. I believe it will be a very great boon to this part of London; in fact, I feel so strongly on this that I should say your enormous advantages would be wasted if you did not take some part in the general scheme of pure education, and that part is quite obvious; you have to make your day school one of the best secondary schools it is possible to imagine. I should have hesitated to give you my opinion on your proper place in education and the excellence of your teaching staff and laboratories if I had not had an opportunity of examining your institution, and, in concluding, I want again to thank Mr. Millis for his very great kindness in showing me over it the other day.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

DR. R. S. LULL, associate professor of zoology at the Massachusetts Agricultural College, has been appointed assistant professor of vertebrate palæontology in Yale University, and associate curator of vertebrate palæontology in the Yale University (Peabody) Museum.

PROF. W. W. WATTS, F.R.S., who is leaving Birmingham to take up the professorship of geology at the Royal College of Science, was entertained by his geological friends in Birmingham on March 23. Prof. Charles Lapworth, F.R.S., who presided, referred to the many services which Prof. Watts had rendered to geological students. Prof. Watts, after acknowledging the presentation made by Mr. J. Whitehouse on behalf of the past and present students, said that he was going to a school which would be in healthy but friendly rivalry to the Birmingham school.

AMERICAN institutions for providing higher education continue to benefit from the generosity of wealthy American citizens. *Science* announces that Princeton University has been made the residuary legatee of the estate of Mrs. J. Thompson Swan, which is said to be worth about 60,000*l*. The late Mr. Edwin Gilbert, of Georgetown, Conn., has left 12,000*l*. for the model farm of the Connecticut Agricultural College. Harvard University has received a gift of 10,000*l*. from Mr. R. W. Sayles, of Norwich, Conn., to establish a fund, preferably for the acquisition, preparation, and maintenance of collections suitable for a geological museum.

THE Board of Education has issued a return showing the extent to which, and the manner in which, local authorities in England and Wales have applied funds to the purposes of technical education, and other forms of education other than elementary, during the year 1903–4. In consequence of the fact that the Education Act, 1902, was coming into operation throughout the year with which the report deals, and that advantage was taken of this fact to initiate a new series of returns of this form of expenditure, the year must be regarded from the statistical point of view as transitional in character. The volume is, in fact, divided into two parts, the first continuing for about half the total number of local authorities the former series of returns, and the second initiating the new series for the remainder. The consequence is that the volume provides no total of the figures dealing with the whole country, and in view of the incompatibility of the bases of the expenditure shown in the two parts, such totals would only be misleading.

THE 1906 issue of the "Register and Official Announcement" of the Clark University, Worcester, Massachusetts, has been received. Among other interesting information, it may be noticed that the University has several funds for the endowment of fellowships. A sum of 600*l*. is now available for junior and senior fellowships from the George F. Hoar fund of 20,000*l*., provided by the generosity of Mr. Carnegie. There are in addition a citizen's fund of 1000*l*., the income of which is to be used for the aid of "some one or more worthy native-born citizens of the city of Worcester

who may desire to avail themselves of the advantages of the institution," and the Field fund of 100*l.*, the income of which is "to provide for the minor needs of a scholar or fellow." These fellowships are intended for young men and women of promise who desire to pursue post-graduate studies in order to fit themselves for intellectual careers. In general, those intending to devote themselves to some special branch of learning are preferred to those directly fitting themselves for one of the "three learned professions."

AT the Convocation of the Calcutta University on March 3, the Vice-Chancellor, Sir Alexander Pedler, dealt with the work of the University during the period 1873–1905. He said that the number of schools sending up candidates to the matriculation examination of the University was three times greater at the end than at the beginning of the period. In the same interval the number of colleges in connection with the University increased from fifty-two to eighty-one, and the number of professors and lecturers in these colleges from 278 to 717. Sir Alexander Pedler went on to ask, Has the University in any way troubled itself to secure that this expansion has been accompanied by the provision of three or four times the number of equally well trained and experienced professors and teachers? Has the University ascertained that the new schools and colleges are equal in quality to those of older and more mature growth? Are three or four times as many well trained or well paid teachers at work in the colleges and schools as thirty years ago? Are there three times as many professors or teachers for the colleges, trained in all the modern developments of western learning and acquainted with all the most recent discoveries in science as there were thirty years ago? To all these questions he said a direct negative must be given. The Government, which in its colleges ought to take the lead in such matters, has allowed a reverse policy to go on, and while in 1873 in Bengal the number of European professors or Indian professors with European training in Government colleges was thirty-one, in 1905 the number had fallen to twenty-seven, while the number of Indian or Indian trained professors had increased from nineteen to sixty. In university work in European countries and in England, when the number of students under instruction in colleges is compared with the number of professors and lecturers in various subjects engaged in teaching them, it is found, Sir Alexander Pedler said, to be about ten students to each professor. In the case of American technical colleges, frequently the ratio works out at one professor to seven or eight students. At the Michigan University one professor for every six students is found, and also at the Toronto University. Turning to the case of India, in the arts sections of certain colleges affiliated to the Calcutta University, for every professor there are such numbers of students as fifty-three or forty-six, and other similar numbers, or from five to nine times as many students as in other countries.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 18.—"A Study of the Mechanism of Carbon Assimilation in Green Plants." By Francis L. **Usher** and J. H. **Priestley**. Communicated by Prof. W. M. Travers, F.R.S.

(1) The photolysis of carbon dioxide may take place outside the plant in absence of chlorophyll, provided one of the products is removed.

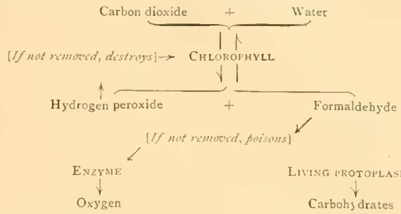
(2) The normal products of the photolysis are hydrogen peroxide and formaldehyde, though under certain conditions formic acid may be formed.

(3) In the plant the decomposition of the hydrogen peroxide is provided for by a catalysing enzyme of general occurrence.

(4) The condensation of the formaldehyde is dependent on the healthy condition of the protoplasm.

There are therefore three factors essential to photosynthesis from carbon dioxide and water in the plant; they are (1) vitality of the protoplasm, (2) presence of a catalysing enzyme, and (3) presence of chlorophyll. If any one of these factors be interfered with, the process of photosynthesis ultimately comes to an end, through the destruction of the optical sensitiser, chlorophyll.

The relations between the various factors in this process may be diagrammatically expressed thus:—



Society of Chemical Industry, March 5.—Mr. A. G. Salamon in the chair.—The ignition of nitro-compound explosives in small arm cartridges: W. D. **Borland**. The action of the igniter, *i.e.* the percussion cap, is to eject through the fire holes of the case a mixture of solid and gaseous products at temperatures between 2400° C. and 3200° C. in such quantity, volume, and time that the initial resistance of the bullet or shot is overcome before the bulk of the charge of powder develops its full energy, but without any hesitation which may upset alignment or perceptible "hang-fire." The rapidity with which these gaseous and solid matters are applied to the powder is determined by exploding the percussion cap in a hollow steel cylinder provided with a hardened steel plunger and resting upon a crusher lead. The proportion which the crushing pressure bears to total energy is found in practice to be a trustworthy guide to the rapidity with which the heat of the igniter is applied to the explosive, and consequently to the ratio which chamber pressures in the small arm bear to observed velocity of projectile. The volume of the gaseous matters in relation to the surface of the explosive can be readily determined. These must be large enough to ensure sufficiently high chamber pressures being set up for the most efficient combustion of the powder. The temperature of ignition was determined by radiation methods of observation, the cap being exploded into a glass tube and the radiation intensity of the solids observed by comparison with a radiant of known intensity, the portion of the spectrum chosen being in the neighbourhood of 6563 wave-length. The paper includes tables illustrating the action of different igniters on different explosives, both sporting and military, and tracing the effect of total heat energy and temperature of igniter upon velocity, pressure, and rapidity of ignition observed in ballistic trials.

Zoological Society, March 6.—Mr. C. S. Tomes, F.R.S., vice-president, in the chair.—A specimen of *Rana goliath*, obtained by Mr. G. L. Bates at Efulen, in South Cameroon: G. A. **Boulenger**. This frog measured 10 inches from snout to vent, and was much larger than any frog hitherto known.—"Flying" snakes: R. **Shelford**. The power of "flying" has been recorded by natives to be possessed by three species of snakes in Borneo, viz. *Chrysopelea ornata*, *C. chrysochlora* (Opisthoglypha), and *Dendrophis pictus* (Aglypha). All three species have the ventral scales with a suture or hinge-line on each side; by means of a muscular contraction these scales can be drawn inwards, so that the whole ventral surface of the snake becomes quite concave, and the snake itself may be compared to a rod of bamboo bisected longitudinally. By experiments on *C. ornata* it was seen that the snake when falling from a height descended, not in writhing coils, but with the body held stiff and rigid, and that the line of the fall was at an angle to a straight line from the point of departure to the ground. It is highly probable that the concave ventral surface of the snake helps to buoy it up in its fall; it can readily be shown that a longitudinally bisected rod of bamboo falls more slowly than an undivided rod of equal weight.—A series of reports on the zoological

results of the third Tanganyika expedition conducted by Mr. W. A. Cunnington in 1904–5 was read. Report on the fishes: G. A. **Boulenger.** The collection consisted of 300 specimens referable to eighty-four species, twenty-eight of which were new.—Crustacea: Dr. W. T. **Calman.** In addition to the two species already known from Lake Tanganyika, no fewer than ten specimens of new species belonging to the family Atyidæ, including the representatives of two new genera, were obtained. From lakes Nyasa and Victoria Nyanza only a single species was obtained, the widely distributed *Caridina nilotica* (*C. wyckii*). The absence of this common species from the gatherings made in Tanganyika emphasised the isolated character of the Macruran fauna of that lake. All the species found in Tanganyika, and all but one of the genera, were peculiar to the lake. There was no ground for regarding the Macrura of Tanganyika as having any specially "marine" affinities. The other members of the groups to which they belonged, the genus Palæmon and the family Atyidæ, were characteristically, and all but exclusively, fresh-water animals.—Mollusca: E. A. **Smith.** This collection contained examples of thirty-three species, one of which was new.—Fresh-water sponges obtained from lakes Victoria Nyanza, Tanganyika, and Nyasa: R. **Kirkpatrick.** The collection comprised eleven specimens representing five species, one from Tanganyika being new to science, two others from Tanganyika (*Spongilla moorei*, Evans, and *S. tanganyikae*, Evans) having already been recorded from that locality. Small specimens of a fourth species, viz. *Spongilla carteri*, Bowerbank, were obtained from the Victoria Nyanza, and a fairly large specimen of a fifth, viz. *Spongilla biseriata*, Weltner, was collected in a swamp bordering Lake Nyasa. Included in Mr. Kirkpatrick's report were descriptions of two new species and a new variety of fresh-water sponges, based on material obtained from the White Nile.—Oligochæte worms: F. E. **Beddard.** They comprised examples of four new species.—The medusæ of the genus Limnocnida obtained during the expedition: R. T. **Günther.**

Geological Society, March 7.—Sir Archibald Geikie, Sec.R.S., president, in the chair.—The occurrence of limestone of the Lower Carboniferous series in the Cannock-Chase portion of the South Staffordshire Coalfield: G. M. **Cockin.** Silurian limestone underlies the Coal-measures in the southern part of the South Staffordshire Coalfield, and a rock, probably similar, was found in a borehole at Cannock-Chase Colliery. A shaft was sunk some thirty years ago north of the latter locality, but was abandoned. In the waste-heaps, which have remained undisturbed since 1875, a number of fossils belonging to the Lower Carboniferous Limestone have been found. A fault must be presumed to bring Carboniferous Limestone into the position indicated. An account of the strata pierced by boring is appended.—Liassic Dentaliidæ: L. **Richardson.** Among the fossils collected in the cuttings on the new Honeybourne and Cheltenham Railway were many belonging to the family Dentaliidæ, and, as the majority are new, the author has investigated the Liassic members of the family contained in several collections. The growth of the scaphopod-shell is effected by additions at the anterior end, while the posterior end suffers by wear and absorption. The members of this class are essentially marine, inhabiting deep water, and feeding principally on Foraminifera. Eight new species are described, and eight species already known are discussed.

Entomological Society, March 7.—Mr. F. Merrifield, president, in the chair.—Two specimens of *Microdon latifrons*, Lw., a rare dipteron taken in the New Forest in June, 1905: H. W. **Andrews.**—Examples of *Nonagria neurica*, Hb., and *N. dissoluta*, var. *arundineta*, Schmidt, from Germany, with (?) var. *arundineta* from Central Asia, for comparison with *N. dissoluta* and *N.* var. *arundineta* from Kent, Cambridge, and Norfolk: H. M. **Edelsten.**—A variable series of *Gynopteryx gladiaria*, Guen., and its varieties: L. B. **Prout.**—Combs of the honey bee formed on a branch of nut tree, the bees having swarmed late in the year: A. J. **Chitty.** After July the bees deserted the combs, and, having consumed all the honey contained in them, again swarmed on a neighbouring tree.—A specimen of *Prodenia littoralis*, Boisd., which had emerged in a breeding-cage kept, with many others, by Major R. B. Robertson at Boscombe, Hants, for the reception of caterpillars found in that district: Prof. R. **Meldola.** The moth emerged on July 16, 1905. The species, which is figured in Hampson's "Moths of India," is said to have a distribution extending from the Mediterranean subregion throughout the tropical and subtropical zones of the Old World.—A Mantis on a portion of the bark of a tree found by Mr. F. Birch in Trinidad, who stated that its close resemblance to a withered leaf was evidently a protection for aggressive purposes: O. E. **Janson.**—A series of Callimenidæ; a small family of Orthoptera, consisting of two genera, Dinarchus, with the single species *D. dasypus*, Illig., and Callimenus, of which all the known species were included, with the exception of *C. inflatus*, Br., from Asia Minor: M. **Burr.**—Specimens of *Argynnis niobe*, var. *eris*, ♀, from the Pyrenees, Cevennes, and south Tyrolese mountains: H. **Rowland-Brown.** Attention was directed to the remarkable form of the example taken at Gavarnie, in July, 1905, of which the coloration of the upper side of all the wings was ruddy copper-red shot with blue upon the nervures. Whereas specimens of *eris* and other Argynnids from the mountainous regions of central France showed a tendency to maintain constant pale forms, those from the Pyrenees are generally more highly coloured, while the high Alpine forms of Central Europe inclined to melanism.—An original note-book of Burchell's taken to South Africa in 1812: Prof. E. B. **Poulton.** The note-book established the date of the author's birthday, hitherto unknown, to be July 12, while it also recorded, for the first time, the superstitious dread of the native Hottentots for the "death's head moth," known locally as the "devil bee."—Specimens of Pierine butterflies from South Africa, India, and Asia Minor: Dr. F. A. **Dixey.** The specimens illustrated how the under sides of the dry-season forms in the group are apt to take a red tinge, and it was especially interesting to note that the same tendency was manifest in all species collected from such widely separate regions.—Note on the migration of Lepidoptera against the wind, extracted from a report on "The Pearl Oyster of the Gulf of Manaar, *Avicula* (*meleagrina*) *fucata*," by Henry Sullivan Thomas, in the *Madras Journal of Literature and Science*: C. O. **Waterhouse.**—A plague of ants in the Observatory district, Cape Town, South Africa: Colonel C. T. **Bingham.**—Some rest attitudes in butterflies: Dr. G. B. **Longstaff.** The paper was illustrated by numerous specimens arranged upon backgrounds of specially prepared sand-paper approximating to the natural surroundings of the insects in their various habitats.—Observations on the life-history of *Trichoptilus paludum*, Zell.: Dr. T. A. **Chapman.**—Some parasitic hymenopterous insects of North Queensland: F. P. **Dodd.**

Physical Society, March 9.—Dr. C. Chree, vice-president, in the chair.—The velocities of the ions of alkali salt vapours at high temperatures: Prof. H. A. **Wilson.** This paper contains a summary of previous work. It is shown that all results so far obtained are consistent with the view that any salt of cæsium, rubidium, potassium, sodium, or lithium gives in a Bunsen flame negative ions having a velocity of 1000 cm. per sec. for one volt per cm., and positive ions having a velocity of about 80 cm. per sec. This result can be explained by supposing that each salt molecule emits a negative corpuscle which forms the negative ion, and that the rest of the molecule forms the positive ion.—Some experiments on earth-currents at Kew Observatory: Dr. J. A. **Harker.** An account of experiments made some years ago at Kew Observatory on the earth-currents produced by electric traction schemes, and on the disturbances they cause on the self-recording magnetic instruments kept continuously running to register the variations in the declination and the horizontal and vertical forces. Two large earth-plates were buried about 4 feet deep and 200 yards apart, and connected through a photographic recording voltmeter of high resistance. On the traces given, the effect of the trains on the Central London Railway was strikingly shown. The nearest point to Kew is about six miles distant. The same disturbances, and also those due to special traction experiments carried out on the system of the London United Electric Tramway

Company during the period when the Central London Railway was shut down, were also clearly shown on magnetograph curves. The effects are much greater on the vertical force than on the horizontal force or the declination. A second system of investigation was to connect the earth-plates through the primary of a transformer, the secondary terminals of which were connected to a sensitive moving-coil galvanometer of suitable period and damping. The galvanometer recorded a ballastic throw for each movement of a tramway controller, while the slower variations due to magnetic storms were without effect. A telephone similarly connected gave a perceptible sound for each controller movement.

Royal Meteorological Society, March 21.—Mr. R. Bentley, president, in the chair.—South Africa as seen by a meteorologist: Dr. H. R. **Mill.** The lecture was illustrated by a series of lantern-slides from photographs taken during the tour of the British Association in 1905. The places visited included Cape Town, Table Mountain, Durban, Maritzburg, Ladysmith, Johannesburg, Pretoria, Bloemfontein, Kimberley, Bulawayo, the Matoppo Hills, the Victoria Falls of the Zambesi, Salisbury, Umtali, and Beira. During the return journey, Mombasa, Cairo, and the Suez Canal were visited. Photographs were shown of meteorological stations in many of the places named, and the views of the scenery were selected to bring out the climatic features.

CAMBRIDGE.

Philosophical Society, February 12.—Mr. F. Darwin in the chair.—Notes on cycads: with exhibition of a rare species acquired by the Botanic Garden: A. C. **Seward.** The author exhibited a plant of *Cycas Micholitzii*, Dyer, recently obtained by the curator of the Botanic Garden from Messrs. Sanders and Sons. This species was discovered by one of Messrs. Sanders' collectors, Mr. W. Micholitz, in Annam, and described last year by Sir William Thiselton-Dyer in the *Gardeners' Chronicle*, August 19, 1905, p. 142. The author directed attention to the importance of cycads as representing scattered survivals from a remote past, and as plants which still retain traces of ancestral characters.—Respiration and vitality: F. F. **Blackman.**—Experiments on the hybridisation of barleys: R. H. **Biffen.** The behaviour of the more important differentiating characters to be found among the varieties of barley has been investigated.—A comparison of the results from the Falmouth declination and horizontal force magnetographs on quiet days in years of sun-spot maximum and minimum: Dr. **Chree.**

February 26.—Dr. Fenton, vice-president, in the chair.—An indicator for strong acids and bases: Dr. **Fenton.** Reference was made in previous communications by the author to a new condensation product, derived from methylfurfural, which has the molecular formula $C_{11}H_8O_4$. It was pointed out that this substance may have useful applications in organic analysis, since it gives highly characteristic colour-reactions with certain classes of compounds, such as amines and ureas. In the present paper it is shown that the reagent serves also as an indicator of alkalinity, and further, that by condensation with urea a colourless base is obtained which is turned blue with acids, and may therefore be used as an acid indicator.—The action of acid chlorides of acetylenic acids on ketonic compounds: S. **Ruhemann.** The paper gives an account of experiments undertaken with the view of supporting the constitution of the product of the reaction between phenylpropiolyl chloride and acetylacetone, and the formula of the substance formed from it under the influence of secondary bases. The properties of this substance have been found to resemble in every respect those of oxalyldibenzylketone.—The dihydrotetrazines: S. **Ruhemann.** The author has extended his research on tetrazoline, and found that the properties of dimethyltetrazoline differ most markedly from those of tetrazoline.—The velocity of transformation of sugars by alkalies: R. S. **Morrell** and A. E. **Bellars.** Aqueous solutions of glucosates, fructosates, and mannosates of guanidine, potash, and soda undergo slow change indicated by a decline in the rotatory power. The velocity of change, as measured by the diminution of the optical activity of the solutions, is that of a unimolecular reversible reaction. Under the conditions of the experiments glucose and fructose are mutually transformable, the production of mannose and acids proceeding at such a slow rate that glucose and fructose first attain an equilibrium, which is afterwards disturbed by the appearance of steadily increasing quantities of saccharinic acid. In the case of guanidine mannosate solutions, the velocity constant obtained from observations of the fall in rotatory power has nearly the same value as the corresponding one for guanidine glucosate and fructosate, but direct measurement of the rate of disappearance of the mannose gave a very much lower value.—The influence of very strong electromagnetic fields on the spark spectra of (*a*) vanadium, (*b*) platinum and iridium: J. E. **Purvis.** The field strength was 39 980 C.G.S. units. (1) With regard to vanadium, two lines become sextuplets and four lines become quintuplets. There are a number of lines divided into four, whilst the great majority of them become triplets. Also there are a few doublets, and there are about eight lines which do not appear to be affected. The distances of the separated constituents from the normal lines were measured, and the value of $d\lambda/\lambda^2$ calculated; and it is seen that many of the lines may be expressed by the same formula, the appearances of the undivided lines and the separated constituents and the values of $d\lambda/\lambda^2$ being essentially identical. (2) Similarly, with regard to the metals Pt and Ir, there are lines of both metals which may be grouped together as possessing identical $d\lambda/\lambda^2$ values, and the normal lines and separated constituents of which are similar in appearance. (3) In several instances the values of $d\lambda/\lambda^2$ for the several constituents seem to be simple multiples of each other.

PARIS.

Academy of Sciences, March 19.—M. H. Poincaré in the chair.—Observations of nebulæ: M. **Bigourdan.**—The distillation of titanium and the temperature of the sun: Henri **Moissan.** The boiling point of titanium is very high, and it was necessary to employ a current of 1000 amperes at 55 volts in the electric furnace to volatilise it readily. The distilled titanium was obtained on the cold tube mixed with lime, distilled from the furnace body. This lime was removed by acetic acid, and the residue was proved by its chemical properties to be titanium. Taking the temperature of the electric arc as 3500° C. (Violle), it is clear from the fact that titanium vapour exists in the sun that the temperature of the sun must be above 3000° C.—Benzyl- and phenylborneols and their products of dehydration: the benzyl- and phenyl-camphenes: A. **Haller** and E. **Bauer.** The secondary benzylborneol was prepared by the reduction of benzylcamphor, and its dehydration by phthalic anhydride; formic acid and pyruvic acid gave rise to the α-benzylcamphene. The tertiary benzylborneol was prepared by Grignard's reaction from camphor; its dehydration gave an isomeric β-benzylcamphene, the properties and derivatives of which are described.—The facies of variation of certain nepheline syenites from the Los Islands: A. **Lacroix.**—Gennadas, or bathypelagic Peneids: E. L. **Bouvier.**—The sheet of the Geological Survey, on the scale of 1 : 80,000, dealing with the region of Gap: Michel **Lévy.**—Functions which depend on other functions: Vito **Volterra.**—Observations of the Kopff comet (1906*b*) made with the bent equatorial of the Observatory of Lyons: J. **Guillaume.** The observations were made on March 5, 6, and 7. The comet appeared as a nebulous star of 15″ diameter and about 10·5 magnitude.—Observations of the comet 1906*b* made at the Observatory of Algiers with the 31·8 equatorial: MM. **Sy** and **Villatte.** Observations were made on March 5, 6, 7, and 8.—A new solution of the problem of magnetic induction for an isotropic sphere: Tommaso **Boggio.**—The resistance of emission of an antenna: C. **Tissot.** A discussion of the most favourable conditions for using a thermal indicator as a receiver of Hertzian waves.—The mechanism of the positive light: P. **Villard.** The positive column in a Geissler tube is regarded as a chain of gaseous particles traversed by the current. It still remains to be determined whether the emission of light is due to the passage of the current or to the progressive dislocation of the chain by the shock

of the negative ions.—Antimony and sulphide of antimony: MM. **Chrétien** and **Guinchant**.—The action of the amino-ethers and imino-chlorides on organo-magnesium derivatives: R. **Marquis**. An attempt at a new general method for the synthesis of ketones, starting with the imino-ether R.C(OR):(NR). The yield in the case of benzophenone is good, but the method is not general. In some cases the imino-chloride gives better results.—The preparation of glycidic ethers and of aldehydes in the hexahydroaromatic series: Georges **Darzens** and P. **Lefébure**. The glycidic esters were obtained by the interaction of chloracetic ester with cyclohexanone in the presence of sodium ethylate. The aldehyde is prepared from the glycidic ester by heating in a vacuum. The reaction has been applied successfully to homologues of cyclohexanone.—The structure and probable origin of the magnetic iron ore of Diélette, Manche: L. **Cayeux**. Conclusions as to the mode of formation of the ore are drawn from a micrographic study.—The gasteropods collected by the Charcot Antarctic Expedition: A. **Vayssière**.—The structure of the sporal wall of the Myxosporidia: L. **Léger** and E. **Hesse**.—A genus of lamellibranchs with multiple mouths: Paul **Pelseneer**. The genus Lima is characterised in its normal condition by having two symmetrical buccal orifices, each of which leads directly into the œsophagus.—X-rays and genital activity: F. **Villemin**.—The disease of wine (Graisse): E. **Kayser** and E. **Manceau**.—The toxin and antitoxin of cholera: MM. **Brau** and **Denier**. The serum of animals which have received the toxin under the skin possesses very slight antitoxic power. The antitoxic power of the serum becomes much more marked when the toxin has been injected into the veins.—The laws of muscular elasticity and their application to energetics: Charles **Henry**.—Some new palæontological data on the Devonian of western Ahenet, Central Sahara (expedition of MM. R. Chudeau and E. F. Gautier): Emile **Haug**.—The fauna of the Lower Coal-measures of Baudour (Hainaut): J. **Cornet**.—The flora of the same: Armand **Renier**.—Chalk and clay on the sea floor: J. **Thoulet**.

DIARY OF SOCIETIES.

THURSDAY, MARCH 29.

ROYAL SOCIETY, at 4.30.—On the Dilatational Stability of the Earth: Lord Rayleigh, O.M., P.R.S.—On the Observations of Stars made in some British Stone Circles. Second Note: Sir J. Norman Lockyer, K.C.B., F.R.S.—The Calculation of Ellipsoidal Harmonics: Sir William D. Niven, K.C.B., F.R.S.

ROYAL INSTITUTION, at 5.—Internal Combustion Engines: Prof. B. Hopkinson.

CONTENTS.

THURSDAY, APRIL 5, 1906.

IONS, ELECTRONS, AND CORPUSCLES.

Les Quantités élementaires d'Électricité: Ions, Électrons, Corpuscles. Mémoires réunis et publiés par Henri Abraham et Paul Langevin. Two volumes. Pp. xvi+1138. (Paris: Gauthier-Villars et Fils, 1905.) Price 35 francs.

THIS very important work, which has been brought out by the French Physical Society under the joint editorship of MM. Abraham and Langevin, consists of a series of digests of the memoirs on which the foundation of the electrodynamic theory of matter is laid. In some cases *résumés* of their researches have been written especially for this work by the original authors, but in the majority of instances the papers have been dealt with by abstractors. The value of this method depends entirely on the insight which is brought to bear upon it, and the task must have been particularly difficult in the present instance owing to the great variety of the material concerned, since many of the investigations are purely experimental, whilst others require all the skill in abstract reasoning possessed by the pure mathematician. The excellence which we should expect from the names of the editors, one of whom, M. Langevin, has himself made extensive and valuable contributions to the subject, is completely justified by the result. Whenever it was consistent with the necessary brevity, the abstractors have kept to the original words of the author, and, so far as the reviewer has been able to discover, no author can claim that his views have been misrepresented in any important particular.

The book will be heartily welcomed by all who are interested in the development of the electron theory, whether it be in its most general aspect as a fundamental theory of physical phenomena or in its extremely interesting applications to such complex branches of the subject as the conduction of electricity through gases and radio-activity. It is true that we have a number of books, such as J. J. Thomson's "Conduction of Electricity through Gases" and "Electricity and Matter," Larmor's "Æther and Matter," Poincaré's "Électricité et Optique," Stark's "Die Electrizität in Gasen," and Rutherford's "Radio-activity," which in one way or another contain the whole of the material of the two volumes under review; but in these cases the material has usually been selected, often, of course, with gain of interest, so as to emphasise the point of view of the particular author. In the present work, on the contrary, we are furnished with an account of each portion of the subject as it developed itself in the mind of its discoverer. The work therefore fills a distinct lacuna in the literature of the subject.

Recent advances in electrodynamics have placed the fundamental principles of physics in an interesting but not altogether satisfactory position. By considering the energy of the electric field, J. J. Thomson showed, many years ago, that a moving electric charge possessed a spurious mass due to the disturbance it created in the ether through which it was moving. This idea has been more than confirmed by the experiments of Kaufmann on the mass of the Becquerel rays or negative electrons. These experiments show that the *whole* of the mass of these electrons is of electrical origin, and is due entirely to the motion of their electric charges. The work of Lorentz and Larmor has given very good reasons for supposing that all matter consists solely of electrons, so that we are forced to the conclusion that the mass of all matter is due to the electrical charges of its ultimate particles.

The reasoning by which this result has been arrived at is dynamical in character, and is therefore based on mass, space, and time as fundamental conceptions. Thus, by the application of a system of thought in which mass is a fundamental conception, we have succeeded in resolving the idea of mass into something, viz. electricity, which lies outside the system.

There appear to be two ways of escape from the confusion implied by this paradoxical result. The first is to resolve electricity into the mass motion of a mechanical ether, and thus to make everything again consistent with the fundamental laws of mechanics. Attempts to construct a dynamical theory of the ether have continually been made ever since the ether began to figure in the literature of exact science. The most successful hitherto has been that of Larmor, which made the ether a perfect fluid composed of gyrostatic atoms. According to this view, which has been criticised by Poincaré in his "Électricité et Optique," the velocity of the ether is along the lines of magnetic force. We have, however, good grounds for thinking that the drift velocity of the ether is proportional to the vector product of the electric and magnetic forces, and it is probable that the successful ether theory will furnish an explanation of this result.

The second way of escape is to take the equations of the electromagnetic field as ultimate relations which are empirically given and of which there is no "explanation." By making energy the fundamental conception, we could then obtain a consistent scheme which would not involve the idea of mass in any fundamental way. The equations of motion of any material system could then be obtained by an appropriate variation of the energy function, which of course contains only electric and magnetic terms, and the results expressed in terms of force subsequently if required. On this view the momentum in any system is obtained as the volume integral of the vector product of the electric and magnetic forces, and mass is simply the vector coefficient which results on dividing the increase in this by the corresponding increase in velocity. This method of stating the case, which makes mass a very secondary conception, will at once be recognised as our old friend the "energetic" view of things, and the electrodynamic explanation of mass may justly be regarded as a great triumph for energetics. The considerations which have been brought forward in the preceding paragraph show, however, that the solution in terms of

A A

energy is not the only solution of the problem, and it remains for the future to decide which of the two is the more convenient and the more fundamental. The "energetic" system of physical philosophy suffers by being intangible and lacking in imaginative stimulus, whilst the material it makes use of in order to build up a picture of the phenomena of nature is not characterised by the simplicity which is desirable in relations of so ultimate a character.

Returning to the book under review, we find, naturally, that a great deal of it refers to the important investigations on the charge, mass, velocity, and other properties of ions and electrons. These have been described with that excellence which characterises the whole production. The reader will find a particularly satisfactory account of Townsend's very exact investigations on ionisation by collisions.

There is a minor point which may be criticised, and that is the prominence given to Moreau's results on the velocity of ions produced by metallic salts in flames. That investigator found that the velocity of the negative ions varied in an unexplained way with the concentration of the salt and the atomic weight of the metal, whereas H. A. Wilson found it to be independent of both these factors. The editors appear to have overlooked the experiments on this subject of the last-named author.

With this slight exception, we have nothing but praise for the whole work, and heartily congratulate the French Physical Society and all who have been concerned in its production. We hope that they will be able to bring out more volumes of a like kind as the development of the subject proceeds. It will be remembered that a few years ago the French Physical Society published a very important series of memoirs, on all branches of physics, which had been communicated to the International Congress at Paris in 1900. The extraordinary activity of the society in this way must command the admiration and gratitude of physicists in every part of the world.

O. W. Richardson.

ANOTHER PLEA FOR RATIONAL EDUCATION.

On Professional Education, with Special Reference to Medicine. An Address delivered at King's College, London, on October 3, 1905. By Prof. T. Clifford Allbutt, F.R.S. Pp. vi+80. (London: Macmillan and Co., Ltd., 1906.) Price 2s. net.

"THERE is no state so perilous as that in which things seem good to us, and at present in England the schoolmaster is complacent, the public indifferent." So Prof. Allbutt generalises early in his address, directing attention, however, in a footnote, to a single exception in the case of the headmaster of the Perse School, Cambridge. Though many more earnest schoolmasters anxious to reform scholastic methods could be named, thoughtful observers of English educational procedure must admit—in spite of the current bickerings among politicians as to religious instruction in elementary schools—that the schoolmaster's policy of *laisser-aller* and the apathy of the public are, and have been, the chief causes of the chaotic and rudimentary state of our secondary education. For half a century it has been dinned into the ears of statesmen, parents, and schoolmasters that no system of higher education, whether academic or technical, can prove successful in the absence of a sane, modern, and broad supply of secondary education given by rationally trained teachers. Prof. Allbutt is to be congratulated upon ranging himself on the side of the prophets, and though for the present he may be a voice crying in the wilderness, his able advocacy of the introduction of sweet reasonableness into our secondary schools will some day be counted unto him for righteousness.

A few of Prof. Allbutt's lessons to the schoolmaster may be quoted with advantage. "The scientific study of facts is the lever by which liberal culture has been re-awakened, and we are beginning to see that the ideas and methods of natural science, instead of being merely curious or commercial, are, if not the flower of education, at any rate the stem and branches." "On both 'sides' [of most schools], while the memory is exercised, and the intellect somewhat called upon, the imagination, the centre of creative life, the source of great action, is left out in the cold." The teacher who fears the baneful effects of specialisation may note this:—"I am satisfied that if the two main coefficients of mind—the intellect and the imagination—are fostered, it proves best in the end to promote development in each person on the lines of his own nature." But we have kept what in our judgment is the most important quotation—trite though the advice is—to the last:—"It is not so much *what* a man is taught as *how* he is taught it."

This advice leads naturally to the consideration of the present secondary school curriculum. Not every essential part of a wide subject can be included in a single address, but it is to be regretted that Prof. Allbutt has so little to say on the simplification and lightening of the absurdly congested time-tables of most schools. It is true that we are told that the current teaching of Greek and Latin is a parody of education, and that, like Sir William Ramsay, Dr. Allbutt considers chemistry is not a good subject for boys, but some guidance in the direction of a ruthless cutting down of the number of subjects at present studied by young boys would have been welcome. It is in this direction that the schoolmaster has a right to look to the man of science for guidance. Cannot physiologists and psychologists agree together as to what groups of faculties should be trained during the years of school-life, and, with the help of pedagogical experts, decide which groups of subjects best assist such training? Until this is done, or until some masterful genius filled with the pedagogic passion arises who will solve this most pressing of educational problems, secondary education will continue to be a process of filling the minds of boys and girls with pellets of information in a multitude of subjects, and of loading the verbal memory with a brecciated congeries of unrelated facts.

On the tertiary, or university, stage of education

Prof. Allbutt speaks with authority and full knowledge. He points out to the medical student who through comparative indigence has to proceed from the secondary to the medical school without the initiatory university course with which his more opulent contemporary is favoured, that "there is no difficulty, at any rate in university education, in using for general training the broader principles of any one of the professional faculties." Applying his principle already quoted, that it is not what is taught but how it is taught, Dr. Allbutt shows how professional studies may be made sources of culture and broad ideas by the non-university medical student. But there is in no sense a disparagement of the unique value of a good university course, with its chances of intercourse with many types of intellect and the opportunities the student has of learning the best which has been done and said in the world.

The question of examiners and examinations is dealt with also. We are told that "the professional examiner, he who makes it his business to range from place to place imposing mechanical tests wholesale, is one of the new terrors of life." We are not introduced, however, to the evil effects of examinations upon the examiners. The examiners are, in many cases, distinguished men of science who eke out insufficient emoluments by undertaking examining work in their leisure hours—time which, in a rationally organised system that recognised the workman to be worthy of his hire, would be devoted to research work. Enough has been heard of the evil effects of examinations upon students, and, indeed, much has been done in the direction of judicious inspection to remedy these, and it is time to recognise that the employment of eminent leaders in science to do the work which competent teachers can perform better is an improvident use of our best intellects.

We notice, in conclusion, that Prof. Allbutt sums up the end of education to be action. "We learn, that we may do," he says. The educated man must not rest satisfied with his education, and be content selfishly to enjoy the intellectual gratifications placed at his disposal. Like each one of us, the educated man is one member of a complex society with many needs to be satisfied, many abuses to be swept away, many wrongs to be redressed. The privileges the educated man has enjoyed, and the sources of satisfaction his education has revealed to him, should serve as incentives urging him to work for the advancement of his race and the further development of human society.

A. T. S.

A MARE'S NEST.

The Utilisation of Nitrogen in Air by Plants. By T. Jamieson. Pp. 82+18. (Aberdeen: The Agricultural Research Association, 1905.)

MATTHEW ARNOLD has somewhere a finely ironical passage in which he comments upon the British habit of labelling its institutions with a great name without considering whether they possess any great thing to correspond, and certainly the name of "Research" has rarely been more taken in vain than in the present publication. The Agricultural Research Association appears to be a body of gentlemen in the neighbourhood of Aberdeen who maintain certain experimental plots under the direction of Mr. T. Jamieson. It is further assisted by grants from the County Council and from the Board of Agriculture, and it has issued the above report for 1905, heralded by some startling preliminary trumpets in the Scottish Press. Briefly speaking, Mr. Jamieson claims to have "discovered" "that plants generally absorb free nitrogen directly from the air, and transform it into albumen." He proposes to wipe out agricultural science between the dates of De Saussure and himself, writing, indeed, with a curious resemblance to the amateur speculations of sixty years ago.

Mr. Jamieson begins by demolishing, to his own satisfaction, the theory that leguminous plants fix nitrogen by the agency of bacteria, and the quality of his argument may be gauged from the following passage:—"It should be borne in mind, also, that bacteria were *never proved to be present*. The small particles found in the tubercles were merely *assumed* to be bacteria." What are we to say to a man who proposes to dismiss the nineteen years' work of some scores of investigators in every country by denying a fact he could demonstrate to himself at any moment had he the most elementary acquaintance with the manipulation of bacteria? But no; Mr. Jamieson prefers to speculate on his own, without even reading up the subject. There is a curious footnote on p. 29 which, we imagine, is meant to display Mr. Jamieson's acquaintance with the literature of nitrogen fixation; a list of authorities is given, equally amazing as regards either its inclusions, its omissions, or its spellings of proper names. Beyerinck appears variously as Burginck and Beirjerenck. But when we leave Mr. Jamieson's criticism and turn to his constructive work the result is even more amazing. He takes an ordinary plant, spurrey, for example, and finds certain hairs on the leaves. To ascertain the purpose of these hairs he applies to them iodine or some other reagent capable of staining proteid. He finds that the tips of these hairs, which are at first empty and then become green with chlorophyll, give later a reaction for albumen, which disappears again as the hairs age. "If the formation of albumen takes place in the tip of this hair, one would expect to find its absence in the early stage, its presence in the later or active stage, its discharge through the channels and round the cells of the plant, and its possible absence in the latest stages—and this is what has actually been found."

"The evidence that nitrogen is absorbed by these tips, and is there fixed and manufactured into albumen, is thus as complete as could well be desired." "The direct absorption of nitrogen, and its direct fixation as albumen, thus seems demonstrated even more satisfactorily than is possible by chemical analysis," and none, accordingly, is attempted. "'Tis safer so," as the American poet puts it. Mr. Jamieson does not bring forward a single experiment to demonstrate that nitrogen has been fixed by any of his plants; this fundamental fact (?) he assumes.

The fact that many investigators like Boussingault and Lawes and Gilbert found no fixation of nitrogen during the growth of plants Mr. Jamieson dismisses on the ground that the plants under experiment had not attained their normal vigour, forgetting that Lawes and Gilbert had dealt with and dismissed this very point in their field experiments upon root crops. Mr. Jamieson even argues that the growth of the leafy turnip crop with small or no nitrogenous dressings implies that the crop has drawn its nitrogen from the atmosphere, whereas this is the standard example in the lecture-room of how the great reserves of nitrogen in the soil can be made to feed the plant if nitrification be promoted by the frequent cultivations and the high soil temperatures which characterise the growth of the turnip crop.

It is on this sort of foundation that Mr. Jamieson proposes to re-build the whole edifice of agricultural science; really the thing would be amusing were it not so dangerous and discreditable to the cause of scientific research. Mr. Jamieson has a following. Putting aside his official backing, and the dukes, earls, and marquises who figure as patrons, there is a body of solid farmers and landowners who sit under him and take advice on practical matters which they suppose to represent the last word of science. Accustomed to the amenities of theological disputation, these men like their agricultural science in the same style; not the dry light of reason, but a strenuous assertion of a monopoly of the truth, rhetoric and passion, and a vigorous denunciation of the other side—all these they get from Mr. Jamieson. But it is a windy diet, and sooner or later disagrees with the subject, whereupon science gets the blame.

A. D. H.

OUR BOOK SHELF.

Technical Methods of Ore Analysis. By A. H. Low. Pp. x+273. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1905.)

This book is of interest as showing the exact methods of analysis of ores in use in the United States at the present time. The author is a member of a well known and old-established firm of analysts and assayers in Denver whose results are accepted with respect by miners and smelters in the western States. It is unusual for such a man to publish exact descriptions of the methods used in his office, as any discoverable flaw in a method might be seized on and magnified by his rivals with prejudicial results to his business. Now that Mr. Low has shown so much courage, his example may be followed.

The book contains detailed descriptions of the estimation of the ordinary constituents of ores, omitting all "fire methods" of assay. The details are minute enough to be tiresome in reading the book through, the account of the precautions to be taken in volumetric analysis, for example, being repeated whenever a volumetric method is reached. In this swarm of details the salient points of the methods are lost, and as the headings are somewhat vague, careful search is necessary to find out what method is being described. An analyst must generally read the whole of a section if he wishes to refresh his memory on some particular point, and will count himself fortunate if he has hit on the right section. Nevertheless, the point will probably be in the book, to be discovered by perseverance.

The methods are usually good and carefully described. It seems a pity that Mr. Low should designate the determination of zinc by ferrocyanide the "author's method," without referring to Galetti or Fahlberg, to whom he is indebted for so much, but there is probably no intention to deceive. Also, in the estimation of copper by iodide, the practice of adding a solution of potassium iodide, instead of crystals, is recommended without any warning as to the decomposition of the solution if it is kept for some time. However, the book is generally trustworthy and useful. There is no book like it, and the analyst will naturally have a copy on his shelf.

The Lepidoptera of the British Islands. A Descriptive Account of the Families, Genera, and Species Indigenous to Great Britain and Ireland, their Preparatory States, Habits, and Localities. By Charles G. Barrett. Vol. x. Pp. 384. Heterocera: Pyralidina Tortricina. (London: Lovell Reeve and Co., Ltd., 1905.)

Since our notice of the last volume of this work entomologists have to regret the death of the accomplished author, well known as one of the best practical lepidopterists in England long before he commenced the elaborate monograph which he did not live to complete. Hitherto, however, there has been no interruption in the publication of the successive parts, and we understand that the manuscript was left practically complete to the end of the Tortricina, which is the more satisfactory as the Tortricina are a large and difficult group which have been somewhat neglected by most British lepidopterists, but to which Mr. Barrett devoted special attention.

The families included in vol. x. are Pyralidina; Phycitidæ (conclusion), 13 genera (Cateremna to Plodia); Anerastiidæ (genus Anerastia), Crambidæ (6 genera), Galeriidæ (5 genera), Tortricina, Tortricidæ (17 genera), Cnephasidæ (5 genera), Lozoperidæ (7 genera), Sercoridæ (commencement, 4 genera).

The general arrangement of the present volume is similar to that employed in preceding volumes, and the remarks on the habits of the insects are detailed and interesting. For example, we are told that the first species in the volume (*Cateremna terebrella*, Zinck.) has a curious habit of emerging during thunderstorms, these being, as is well known, frequent in the eastern counties. The history of the various species, small and inconspicuous as many of them are, is very fully given throughout.

W. F. K.

A First Reader in Health and Temperance. By W. Taylor. Pp. iv+219. (London, Westminster: Church of England Temperance Society and G. Philip and Son, Ltd., n.d.) Price 1s. 6d.

In this small book the instruction is given in forty-three lessons wherein all difficult words are avoided so far as possible, and when such words are necessary their meaning is always explained. The elementary matter dealt with is suitably illustrated, and the work is in every respect to be commended.

The various physiological requirements of the body are explained in simple language, and it is shown that alcohol is not only unnecessary but may be actually detrimental to every healthy function. Abstention from alcohol is, in fact, the dominant text of the book.

It is not easy to conceive a book better suited to meet the needs for which it is designed. The subject of personal hygiene is made interesting and it is treated in a very happy and lucid manner, appropriate to the intellectual powers of young children, for whom the book is designed to serve as a first reader.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Spectral Series in Relation to Ions.

As I have already shown (*Physik. Zeitschr.*, vi., 892, 1905), the observation of the Doppler effect on the Kanal-strahlen permits the detection of spectra emitted by the positive ions (Kanal-strahlen). I have made such researches on Kanal-strahlen in hydrogen, potassium vapour, and mercury vapour in cooperation with Messrs. S. Kinoshita, K. Siegl, and W. Hermann. We shall give details of our methods and measurements in separate papers; but here I wish to state the principal results of the researches, together with some general conclusions.

The series of lines (Hα, Hβ . .) of hydrogen is a first subordinate series. Its lines are revealed by accurate analysis as pairs or doublets. The difference of wave-lengths of the two components is, as Michelson has found (*Phil. Mag.*, xxxiv., 280, 1892), 0·14 Ångström unit for Hα and 0·08 Ångström unit for Hβ; the measurements made by Ebert (*Wied. Ann.*, xliii., 790, 1891) give 0·132 Ångström unit for Hα. In every other first subordinate series of doublets, and also in the case of hydrogen, the difference in oscillation frequencies of the components of the doublet is constant throughout the series; this difference is for Hα 0·33, for Hβ 0·34 per 1 cm. path *in vacuo*. My previous and recent observations lead to the conclusion that the first subordinate series of doublets of hydrogen has as carriers monovalent positive atom-ions, *i.e.* atoms of hydrogen which have lost a single negative electron.

A second subordinate series of lines of the hydrogen has been observed in certain stars. From their spectral position, Rydberg (*Astrophys. Journ.*, vi., 233, 1897) has calculated the principal series of hydrogen; he gives to the first line of it the wave-length 4687·88 Ångström; this line has been observed in stars with bright lines. It is found also (somewhat displaced) in all spectrograms I have taken of the kathode rays or Kanal-strahlen, partly alone and partly in cooperation with Mr. Kinoshita. This line of the principal series—it may be termed Hβ—shows also the Doppler effect in the Kanal-strahlen, the quantity of the effect being the same as for the first subordinate series of doublets; the principal series of the hydrogen, which is also composed probably of doublets, has therefore the same carrier as the first subordinate series, namely, the monovalent positive ion of hydrogen.

In cooperation with Mr. Siegl I have further examined another doublet of a principal series, namely, the second doublet of the principal series of potassium (λ 4047·36–4044·29). Both components show the Doppler effect in the Kanal-strahlen, and the amount is the same as that calculated for an atom of potassium which has lost a single negative electron. Therefore, in the case of the alkali-metals also, the principal series of doublets has monovalent positive ions as carriers.

In the spectrum of mercury hitherto only series of triplets have been found—a first and a second subordinate series (Kayser and Runge). Using a small concave grating kindly lent to me by Prof. Runge, I succeeded, in cooperation with Mr. Hermann, in examining the Doppler effect on the lines of mercury. It was found that all components of triplets, and further all triplets of a series, have the same positive ion as carrier, and, moreover, the lines of the first and of the second series show the same Doppler effect in type and quantity. Both series of triplets of mercury have therefore the same carrier, the bivalent positive ion of mercury; for the Doppler effect really found agrees in quantity with the effect calculated theoretically for an atom of mercury which has lost two negative electrons.

The lines of mercury not belonging to the series of triplets show likewise a Doppler effect, but there is a difference in character and amount between them and the lines of the two series of triplets. There are lines which show a larger effect than the series of triplets; the carrier of these lines is therefore a positive ion of mercury of higher valency, *i.e.* an atom of mercury which has lost more than two negative electrons. To these lines of higher valency belongs the line λ 4078·1.

Finally, there are lines in the spectrum of mercury which show a smaller Doppler effect than the lines of the series of triplets; their displacement is roughly 1·5 times smaller than that of a line of a triplet of equal wave-length. Therefore they have as carrier not a bivalent, but a monovalent positive ion of mercury. To these lines belong the wave-lengths λλ 2536·72, 4339·47–3021·64, 3984·08–2847·85. It seems that λ 2536·72 is the first component of a principal series of doublets, that the pair λλ 4339·47–3021·64 belongs to a first, and the pair λλ 3984·08–2847·85 to a second subordinate series of doublets. This being so, mercury confirms the view that the principal and the first and second subordinate series of doublets have monovalent positive ions as carriers.

Generalising the foregoing results, we have come to the following conclusions:—The carriers of the spectra of lines of the chemical elements are positive atom-ions. All lines of a series have the same carrier, and, moreover, the same carrier may emit several series at the same time. The carrier of the principal series and of the subordinate series of doublets is a monovalent positive atom-ion; the carrier of the subordinate series of triplets is a bivalent positive atom-ion; ions of a higher valency emit likewise line spectra, but the structure of these is not yet recognised. The spectrum of an element, for example, that of mercury, may represent a mixture of several spectra, namely, of the spectra of its monovalent, bivalent ions, and of ions of higher valency.

The foregoing results and conclusions are in striking agreement with the results which were arrived at by Runge and Paschen (*Ber. d. Berliner Akad.*, 1902, 380, 720) in their researches on the Zeeman effect of series of lines. They found that the principal series of doublets of all elements examined (Na, Cu, Ag, Mg, Ca, Sr. Ba) show in type and amount, when measured in oscillation frequencies, the same Zeeman effect; this also holds good for the first and the second series of doublets. The first and second subordinate series of triplets show in type and amount another Zeeman effect than the series of doublets; but the series of triplets of different elements are again in the same way broken up by a magnetic field. The agreement of my results with those of Runge and Paschen comes out in the following detail:—The lines of mercury (λλ 2536·72, 4339·47, and 2847·85) referred by me to series of doublets must show in a magnetic field the known splitting up of the lines of the principal and of the subordinate series of doublets. Runge and Paschen enumerate these lines under those which do not show the behaviour of triplets, and, in fact, their statements on the magnetic behaviour of those lines are concordant with that postulate.

It follows from the Zeeman effect that the centres of emission of series of lines are periodically accelerated negative electrons. From the complexity of their magnetic splitting up we may draw the conclusion that these centres of emission—the negative electrons—are coupled in electrodynamic systems; the electrodynamic structure of these systems of negative electrons is for the emission of series of doublets rather than for the emission of series of triplets.

We do not know of spectra of neutral atoms. It follows from the foregoing results that the known spectra of lines can only be emitted if the chemical neutral atoms have lost negative electrons, and thus have become positive atom-ions. Therefore the electrodynamic symmetry of the system of negative electrons in the positive atom-ion is different from the symmetry in the neutral atom. Certain systems of negative electrons have in the positive monovalent ion an electrodynamic symmetry which enables them to emit radiation of electromagnetic energy; this symmetry is characterised by the emission of doublets. Losing two or more negative electrons a neutral atom also gains an electrodynamic symmetry capable of radiation; but the

electrodynamic symmetry in the bivalent ion is different from that in the monovalent ion; it is characterised by the emission of triplets.

Spectroscopically the chemical elements show a uniform behaviour in a striking way. Their monovalent ions emit series of doublets of analogous structure and identical magnetic behaviour; their bivalent ions emit series of triplets likewise of analogous structure and identical magnetic behaviour. From element to element the variables are only the proportions of the spectra or the constants of the laws of the series of doublets and triplets.

Göttingen, March 5. J. Stark.

The Kew Bulletin.

A few words of explanation may be useful to anyone interested in the Kew Bulletin. It was started in 1887, partly to meet a suggestion made in the House of Commons and partly to serve as "an expeditious mode of communication to the numerous correspondents of Kew in distant parts of the Empire." It has been the vehicle for the publication of a vast amount of information of various kinds, some on purely scientific, but mostly on economic subjects. The number of copies printed has necessarily been limited, but it has always been hoped that the Press would aid in the further diffusion of information of general interest to the public.

The volumes before 1892 have long been out of print. To meet this difficulty, selected papers which proved to be of permanent interest have been from time to time reprinted.

Since 1901 the Bulletin has been somewhat in abeyance, though the routine appendices which are required for various purposes have been kept up. The fact is that to produce the Bulletin satisfactorily requires what it has never had—some sort of staff which would be specially charged with it. The volume of work which falls on Kew is little understood. Besides its own routine and administrative duties, Kew acts as technical adviser to all Government departments at home, as well as in a varying measure to India and the colonies. For many years the annual number of letters sent out has averaged about 14,000, which is about two-thirds of that of the Commercial Department of the Foreign Office. The publication of the Bulletin has simply been crowded out.

My functions as director ceased on December 15, but I was retained in a consultative capacity until March 31. In order to give my successor a clear start I have done my best in the interval to clear off arrears. The third and concluding volume of the "Index Floræ Sinensis" has been issued. An eighth volume of the "Flora of Tropical Africa" has been all but passed through the press. The long delayed "Wild Fauna and Flora of the Royal Botanic Gardens" has been published. A catalogue of the exhibited collection of portraits of botanists has been prepared and is in type, and a second edition of the "Hand-list of Ferns and Fern-allies cultivated at Kew" is in the printers' hands. A third quinquennial supplement to the "Index Kewensis" is being prepared for the press.

The continuation of the "Flora Capensis" is being actively pushed forward, and other much needed undertakings are in view.

In order to restore the Bulletin to something like vitality, it was thought advisable to issue in one or more numbers for each year such matter as was available, with title and table of contents. This will allow the annual volumes to be bound, and the series made continuous to the satisfaction of careful librarians. The volumes for 1900 and 1901 are already issued, and the succeeding ones will follow immediately. A word of acknowledgment must be given to the generous aid of the new and active Controller of H.M. Stationery Office in expediting the work.

The director has taken up the publication of the Bulletin from the present year, and will, I hope, be able to continue it, but on a somewhat more elastic plan. No attempt will be made to issue it monthly, but material and documents of general interest will be printed at once.

Kew, March 30. W. T. Thiselton-Dyer.

Interpretation of Meteorological Records.

I quite agree with Mr. Omond's remarks in Nature of March 29 with regard to the heating of downward moving air, that if it had been simply a case of air which had previously been in thermal equilibrium and moved downwards its temperature would have been raised to that of the lower air; but in this case it was a mixture of air and water, and the water would absorb the heat produced by the compression of the air, and, further, any little heating that might not be so absorbed would increase the dryness of the air, and so cause evaporation and absorption of heat.

With regard to the effects of electricity on rainfall, they are much too little understood to be entered on here, but it may be stated that a sudden fall of rain, or an increase in rate of fall, is often observed very shortly after a flash of lightning. John Aitken.

Ardenlea, Falkirk, N.B., March 31.

Request for Prints of Photographic Portraits.

I should be grateful to your photographic readers, whether amateur or professional, who would send me, within the next two or three weeks, waste photographic portraits, to be cut up, mounted, reduced to a miniature scale, and so to be published *without names*. They are wanted in considerable numbers to control results at which I have already arrived, relating to resemblance. Family portraits would be particularly acceptable. I make this appeal, finding it extremely troublesome, as well as costly, to obtain the needed material in other ways. Francis Galton.

42 Rutland Gate, London, S.W.

Peculiar Ice Formation.

As the question of earth-bearing ice-pillars has been recently raised in your columns (pp. 464, 485), there are one or two points to which I should like to direct attention, as they may be of interest to your readers. While working in company with a colleague on Divis Mountain, Belfast, in 1902, our attention was attracted by the peculiar formation of ice so admirably described by your correspondent of March 15. It seemed perfectly obvious that the ice-pillars had, in growing, lifted the earth and stones by exerting a pushing force in the direction of their length, and that without lateral support, putting the expansive force of water on freezing out of the question as an explanation. All doubt on this point was removed by our finding an impression of a nailed boot, made in the mud before the frost, and on which the pillars had grown on all parts of the mud on which there were no impressions of nails, and were wanting wherever the nails had been. This gave a curious effect, as if the boot had been shod with long spikes, each nail being represented by a narrow cylindrical pit an inch and a half deep. The pressure of the nails had evidently destroyed the conditions which led to the formation of the pillars.

I was unable to determine whether the ice in each pillar was in crystalline continuity, but there was nothing to lead one to suspect the contrary. I thought I could distinguish a rude hexagonal form in some of the pillars, but this may have been merely chance. On the whole, it would seem as if the idea that a growing crystal is capable of exerting a mechanical force in some definite direction is not entirely without support. Such a force would go far towards explaining many peculiarities of the natural growth of crystals. Take, for example, the horizontal veins of fibrous gypsum so common in the Keuper Marl. It is impossible to conceive of the formation in soft rocks of a horizontal fissure of the extent of some of these veins, and it is difficult to escape from the conclusion that the growth of the fibrous crystals forced apart the sides of the vein, lifting the enormous weight of rock above. This suggestion is by no means a new one.

W. B. Wright.

28 Jermyn Street, S.W., March 27.

Formula for finding the Date of Easter.

IT may be of interest to some of your readers to know of the following empirical formula—attributed to the famous mathematician Gauss—for determining in an easy manner the date on which Easter falls in any year from 1900 to 2100:—

(1) The number of the year is divided by 19; remainder $= a$.

(2) The number of the year is divided by 4; remainder $= b$.

(3) The number of the year is divided by 7; remainder $= c$.

(4) $19 \times a + 24$ is divided by 30; remainder $= d$.

(5) $2 \times b + 4c + 6 \times d + 5$ is divided by 7; remainder $= e$.

Easter will be the $22 + d + e$ of March, or, if this number exceed 31, it will be the $d + e - 9$ of April.

The calculation for the present year is as follows:—

$$(1) \quad \frac{1906}{19} = 100 + 6 \quad \ldots \quad (a = 6)$$

$$(2) \quad \frac{1906}{4} = 476 + 2 \quad \ldots \quad (b = 2)$$

$$(3) \quad \frac{1906}{7} = 272 + 2 \quad \ldots \quad (c = 2)$$

$$(4) \quad \frac{(19 \times 6) + 24}{30} = 4 + 18 \quad \ldots \quad (d = 18)$$

$$(5) \quad \frac{(2 \times 2) + (4 \times 2) + (6 \times 18) + 5}{7} = 17 + 6 \quad \ldots \quad (e = 6)$$

As $22 + 18 + 6$ is in excess of 31, we take the alternative $18 + 6 - 9 = 15$, on which day of April Easter falls this year.

CHAS. LEIGH.

The Victoria University of Manchester, March 30.

Chinese Names of Colours.

IN your issue of January 11 (p. 246) Mr. Alfred H. Crook writes respecting the name given by the Chinese to a certain tint of blue, which he translates quaintly as "snow-green colour." The following explanation may be of interest to him and to others of your readers.

雪 *Hsüeh*, the word he translates "snow," also means "ice," and to the natives of southern China is far better known in reference to the latter object than to the former, as the same name is applied to both natural and artificial ice.

青 *Tsing* originally meant "clear," "tranquil," "smooth" (applied to water). The change from "smooth water" to the "colour of smooth water" is an easy one, so that a secondary meaning of the word is "sea-green" or "sea-blue." Quite different words are used to express other green tints, such as grass-green, and other blue tints, such as indigo-blue.

Putting the two words together, one finds the meaning of 色 青 雪 (*hsüeh tsing seh*) to be "ice-blue colour" or "blue ice colour." Anybody who has noticed the tint of ice in great masses such as one gets in north China and in Switzerland, and who has seen the colour referred to by Mr. Crook, will agree with me in saying that the name given by the Chinese, far from being fanciful, is very appropriate.

Hong Kong, February 15.

The Adulteration of Butter.

MY attention has been directed to an article in your issue of March 15 on "The Adulteration of Butter" in which your contributor refers to the composition of butter fat as a triglyceride of oleic, palmitic, and butyric acids, or as containing such a substance. Some years ago I traced this opinion to Mr. Bell, a former analyst of Somerset House, who appears to have based his conclusions upon the insolubility of butter fat in alcohol. Butter fat is, however, soluble in alcohol, and I have no doubt whatever that a process of fractional precipitation from this solution would enable us to ascertain with fair accuracy what the real constituents are. My own experiments certainly pointed to a great number of separate glycerides being present, palmitin and stearin separating out in tolerable purity. The separation of the lower fatty acid compounds is more difficult to attain, probably owing to their existence as esters. It would be interesting to know whether the theory of the presence of triglyceride rests upon a more stable foundation than that of Bell's statement.

J. H. LESTER.

Royal Exchange, Manchester, March 17.

YOUR correspondent scarcely does justice to Dr. Bell's observation.

Whether butter fat is completely soluble in alcohol or not depends upon the volume, strength, and temperature of the solvent. Bell showed that when the simple glyceride tributyrin was mixed with melted ordinary fat to the extent of 10 per cent., it could be entirely removed by treatment with warm alcohol. But when butter fat was similarly extracted, from 2 per cent. to 3 per cent. only of the fat was dissolved out, and the soluble portion was not tributyrin. Therefore the butyric acid of butter fat is not present as the simple glyceride tributyrin, but chiefly or wholly as a mixed glyceride. Further, the portion dissolved from the butter was found to contain "soluble" and "insoluble" acids in proportions agreeing closely with those required for the mixed glyceride oleo-palmito-butyrin.

Some years later (Proc. Chem. Soc., 1889) Blyth and Robertson noted the isolation from butter fat of a crystalline mixed glyceride, to which they ascribed the formula of palmito-stearo-butyrin.

The "presence of triglyceride" in butter fat will hardly be questioned; what your correspondent has in mind is, apparently, the occurrence of mixed (*i.e.* complex) glycerides. Many such have been isolated from various natural fats in the last few years; this is, in fact, the most notable feature in the recent chemistry of fats. That complex glycerides exist in butter Bell's and Blyth's experiments leave no reason to doubt, though more rigorous proof of their precise composition is desirable.

March 20. C. SIMMONDS.

The Existence of Absolute Motion.

IN discussing this question it is surely necessary to place stress on the contrast between the places of absolute direction and absolute position in dynamics. The result of observation is that the laws of motion are competent to explain such phenomena as nutation and retain the simple Newtonian form when certain directions which can be found with reasonable accuracy are assumed to be absolute. The contrary assumption, that these directions were not absolute, but moving with absolute angular velocities, say of the order of one degree per second, would necessitate a re-statement of the laws of motion involving great loss of simplicity. In the same way, we cannot without loss of simplicity suppose that the acceleration of the earth with respect to the centre of the solar system differs greatly from the absolute acceleration, and suggest that the material universe has an absolute acceleration of the order of one hundred miles per second per second.

On the other hand, the laws of motion would not be modified in the slightest if the whole universe possessed a uniform and constant absolute velocity, however great that velocity might be, even, for example, ten times the velocity of light. Compared with such a velocity as this, the velocity of the solar system relative to the centroid of the visible stars is probably insignificant. Evidence as to the existence of such a velocity must be sought elsewhere; dynamics alone will not supply it.

Merchant Taylors' School, E.C.

SAILING CRAFT IN EUROPE AND ASIA.[1]

In these days, when sails are falling more and more into disuse for ocean-going vessels, and the construction of sailing-ships is a dwindling industry, it is refreshing to come across a book like this, breathing throughout an intimate knowledge of sailing-ships and sailors, displaying insight into, and sympathy with, the nature of the men who follow the sea on the coasts of many countries, and showing in every page powers of quick observation and ready understanding of all that makes for the efficiency of sailing craft. The author indicates his recognition of the inevitable triumph of the steam-ship in competition with the sailing-ship for purposes of both peace and war, but he rejoices no less in the belief that throughout all time fishing- and coasting-vessels will remain dependent upon sails, and so will constitute a school of seamanship in which the traditions of the past will be maintained. Mr. Warington Smyth describes the volume modestly as "an attempt to record the peculiarity of the principal types of sailing craft in Europe and Asia which I have observed . . . and to consider the causes which have been at work in the development of boats and the results attained under the conditions with which they have had to contend."

This attempt has been eminently successful, and has resulted in the production of a book which is a perfect treasury of information on the subject treated, is well arranged, brightly written, and beautifully illustrated. The author has received the assistance of many competent authorities in special classes of vessels described. Captain Drechsel has dealt with Danish vessels; Mr. Colin Archer, the well known naval architect of Larvik, has been responsible for details of Norwegian types; Mr. Robert Duthie, of the Scottish Fishery Board, has given valuable information in regard to the Scottish fisheries, and other friends have assisted in regard to extra-European types. The descriptions are arranged in geographical divisions, which is not merely the most natural scheme, but also that which best brings into relief the underlying motive of the book, namely, the illustration of the influence of local conditions upon form, type, and sail-plan. Other writers, notably the late Mr. Dixon Kemp, and those who, since his death, have continued the revision of his work on "Yacht and Boat Sailing," have emphasised the influence of local conditions, and gathered large stores of information illustrating the general principle. In most cases these writers have dealt with the subject from a more technical standpoint than that assumed in the volume under review. It must not be assumed, however, that Mr. Warington Smyth has neglected technicalities or unduly sacrificed them to a popular treatment of his subject. On the contrary, for many classes of sailing-vessels he gives the "lines" (or building drawings) and the sail-plans, and his portraitures of both hulls and sails in the vignettes scattered freely throughout the text are admirable in their details. The interest of the book is increased by the introduction of numerous reproductions of famous pictures of shipping, and no pains have been spared by the publisher either in regard to these illustrations or to other features for which he is responsible.

Mr. Smyth excludes from his survey pleasure boats, yachts, and square-rigged vessels, and gives adequate reasons for that course. About one-half of the book is devoted to European types, beginning with the Baltic and Scandinavian countries, and passing to Holland, Scotland, the east coast of England and the Thames estuary, the south and west coast of England, and then to France and the Mediterranean. To English readers, probably the most interesting section of the book will be that dealing with Eastern vessels, including those of the Indian Ocean, the Malay Peninsula, the Gulf of Siam, and China. Here we find special types of great antiquity, differing widely from Western vessels, but well adapted for their special services and surroundings. Mr. Smyth combines philosophical reflection with a yachtsman's enthusiasm and a technical knowledge which goes beyond that of the ordinary amateur, and this fact adds to the charm of his book.

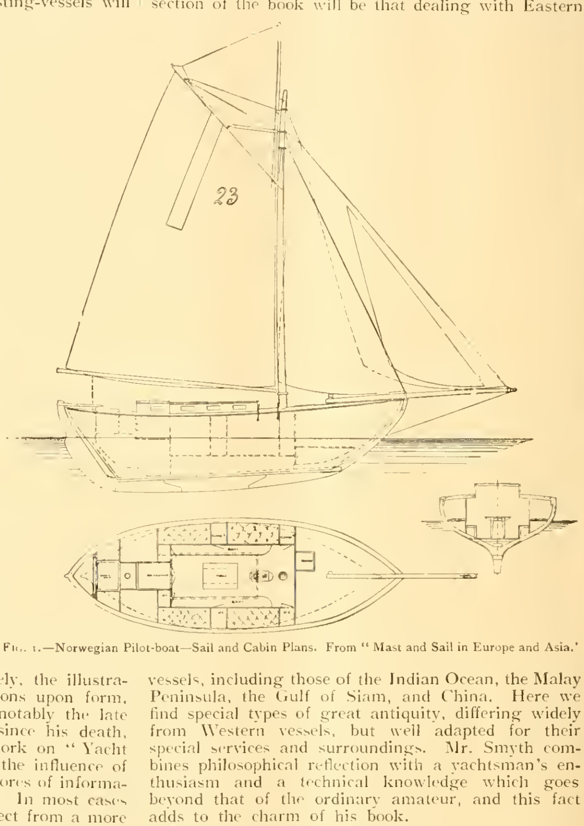

Fig. 1.—Norwegian Pilot-boat—Sail and Cabin Plans. From "Mast and Sail in Europe and Asia."

One quotation may be permitted, even within the limited space available in this notice, as indicating this side of his work. He says:—"It is probably true that the degree of civilisation of any race is remarkably reflected in its boat architecture. The variety of its adaptations to the peculiar requirements of its waters is a measure of its appreciation of the value of the cheapest and most certain method of communication known to man; and it is evidence of

[1] "Mast and Sail in Europe and Asia." By H. Warington Smyth. Pp. xix+448. (London: John Murray, 1906.) Price 21s. net.

its ability to use materials at command and fit them to its needs. The highest degree of civilisation in maritime races has always been marked by activity in boat-building and by variety of design and rig. In no case has this been more notable than in the history of China and of Holland, and in the Adriatic in the fifteenth century, in Europe during the last two centuries and in the United States since 1780. The Negro, the American Indian, and the Slav, on the other hand, have never designed a sea-going boat or cut a sail. It has not been for want of water-ways or of opportunity. It has been simply owing to a lower class of intelligence and to want of originality and enterprise."

Mr. Smyth's allusions to the indirect influence upon character and resource of life and work in vessels equipped with sail power are also notable:—"It is above all in the men who handle sails that the self-reliance which is bred by tempest, darkness and the shadow of the Angel of Death reaches its highest point. The seriousness, from this point of view, of the loss of masts and yards to the Navy has been fully recognised, and it has only been reluctantly acceded to on account of the pressing importance of other more essential forms of training. But amongst the coasters and fishermen of the world the mast and sail more than hold their own; and here a student of the sea will find himself in a by-path of the modern world, among the old thoughts, the old traditions, the old methods, and the old virtues of the great seas. And when this civilisation shall have condemned itself and passed the way of others, the lug-sail and the lateen will still be navigating the deep, conned by other races, but the same grim, great-hearted sailor men."

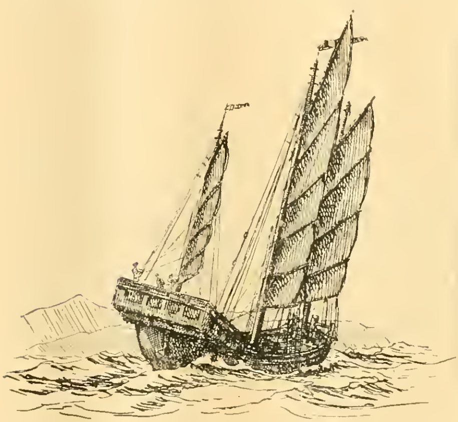

FIG. 2.—Hong Kong Junk. From "Mast and Sail in Europe and Asia."

Enough has been said to indicate that, in our judgment, this book should find a hearty welcome from all who love to sail the seas and manage their own craft, and from all who are interested in the maintenance and development of that hardy race of seamen bred on the coasts of the United Kingdom, and leading a life of hardship, difficulty, and danger which must develop qualities of the highest value to the maritime greatness of the British Empire.

W. H. WHITE.

THE SOLAR ECLIPSE OF 1905.

IT is very satisfactory that reports of the recent eclipse expeditions indicate that at some stations the weather conditions were all that could be desired, because we know that at several stations opportunities for securing good results were frustrated by clouds. The Hamburg Observatory party chose a spot which, however, did not come under the second category, and judging by the first portion of the report published,[1] which deals chiefly with the general arrangements and journey to and from the position of observation, it achieved complete success in all lines of work. The report itself is of great interest, and is accompanied, not only by excellent reproductions from photographs of camp scenes, &c., but by capital pictures of the corona. The style of reproduction here employed is to be highly recommended, and other publishers of reports might with advantage copy the good example set.

The party was not a very large one. It consisted of Prof. R. Schorr, the director of the observatory, Dr. Schwassman, the observer, and an observatory attendant, Herr Beyermann, and they were assisted by Prof. Knopf, director of the Jena Observatory, who joined the expedition.

The station selected and used as the observing position was Souk-Ahras, in Algeria, lying on the railway from Tunis, and to the south-west of Bône. The accompanying illustration shows the station occupied, with the several instruments in position. The work of the expedition was chiefly devoted to the following points:—structure of the inner corona; photography of the outer corona and extensions; a search after intra-Mercurial planets; the determination of the brightness of the corona and the total daylight during the eclipse; contact, meteorological, and other observations. The only spectroscopic work attempted was the employment of a Thorp diffraction grating to secure the spectrum of the corona.

For the attack on the inner corona a horizontal telescope of 20 metres focal length was employed. With this, very excellent photographs were obtained. Perhaps the most interesting part of the account of these photographs is the recording of three or four oval, ring-formed, cloud-like caps which lay at a distance of 4 to 6 minutes of arc above the large prominence on the east limb, and indicated a close connection with the eruptive nature of the prominence. These rings, it may be remembered, were also photographed by the Greenwich Observatory party under the direction of the Astronomer Royal, which observed at Sfax, in Tunisia, so that an independent photographic record of them is very important, as this is the first time they have been caught on the sensitive film. That such phenomena have been previously *seen* will be gathered from the following extract[2] relating to some spectroscopic observations made by Sir Norman Lockyer in 1870:—

"And what was going on, while this was happening? A prominence, obviously with its root some distance from the limb, had gradually travelled beyond the limb; in appearance it became very much more elevated, and seen, as it were, in perspective over the limb; but what I saw first was very rapidly changed, in a way that would be explained by supposing that cyclones were being shot up into the solar air like bombs! the changes in the F line were so rapid and curious. I was not observing with an open slit, so I at once coined the term 'motion forms,' because the forms observed did not in any way represent the shape of the prominence. But the

[1] *Mittheilungen der Hamburger Sternwarte*, No. 10.
[2] "Solar Physics," by Sir J. Norman Lockyer, p. 403.

extreme velocity can be imagined from the great departure of those bright lines from the stable dark line F, seen below them, and not only that, but we can think out the explicit character of this prominence action. *They were really in this case, as already stated, smoke rings thrown up by enormous circumsolar action.*"

We thus see that after the lapse of thirty-five years these "lozenge" forms, as they were then called spectroscopically, have been caught in the mesh of the photographic plate.

For the search after intra-Mercurial planets two objectives of 10 cm. aperture and 4 metres focal length were used equatorially, and plates were exposed for 120 and 63 seconds. So far as the negatives have been examined, no unknown object has been detected, but it is interesting to remark that on both plates Mercury appears of the fifth or sixth magnitude eleven hours after inferior conjunction.

Successful measures were made of the brightness of the corona with a Weber photometer by Prof. Knopf, but the reductions are not yet quite complete.

FIG. 1.—The Hamburg Observatory's Eclipse Camp in Souk-Ahras. The 20-metre coronagraph is on the right, and the twin equatorial planet-finder on the left.

Shadow bands were clearly seen, and the dimensions of those measured were about 50 cm. long and 4 cm. to 5 cm. broad.

W. J. S. LOCKYER.

THE STORY OF AN ENGLISH TOWN.[1]

THE modern changes in literary methods and the demands of the reading public have altered the character of many classes of books, but none has been so much affected as that dealing with topography. The subsidised family history, the elaborate folding pedigrees, plates of armorial bearings or of equally uninteresting tombs of former magnates of the locality, have disappeared from such works, unless their intrinsic interest coincides with that of the subject of the book. Genealogists and students of family history are now provided with publications of their own, surely a change of a practical kind, and one which allows the substantive matter of a topographical work to take its real place. Even when the older fashion is cast aside for the new, however, there are many alternatives in the treatment of local history. Mr. Gordon Home may be said to be thorough in the one he has chosen, for in the course of some 300 octavo pages he traces the story of the district in which Pickering is situated from pre-Glacial times up to the date of his publication, including the geology, the archæology early and later, local legends and folklore; and very good miscellaneous reading he makes of it. The earlier sections, however, can scarcely be said to conform with his title-page, for it is admitted that for many thousands of years after the period of his second chapter no human being yet existed in Britain in the latitude of Pickering, and the town itself would, of course, be even later.

There is, however, no harm in this, and it must be confessed that the admirable material existing in the neighbourhood, and the masterly way in which much of it has been treated by competent hands, offer great temptations to include nature's story as well as man's. The Kirkdale cave is one of the best known of these natural features of the locality, and was exhaustively described by Dr. Buckland in 1822 before the Royal Society, in a paper which is a model of scientific analysis. The physical conformation of the country, the hills around rising to a height of upwards of 1400 feet, naturally provides an admirable field for the observation of the action of ice, and here Mr. Home has taken full advantage of the survey made by Prof. Kendall, while the existence and behaviour of the glaciers in the valleys converging on Lake Pickering in the lesser Ice age are made very clear by the diagrams provided. Naturally enough, there is a good deal of elementary geology in these chapters, and Mr. Home at times also gives his imagination a somewhat free rein, but he does not confuse fact and imagination.

Coming to the later times, where geology gives place to archæological conditions, we are on surer ground; the relics are more plentiful and more directly comparable with similar remains in other localities and even other countries. Hypothesis and even imagination still have their uses, but the more abundant materal should keep the student to the safer zone of comparative archæology. Here again, in the Barrow period, Mr. Home is fortunate in having masters of the craft to appeal to. Dr. Thurnam and Canon Greenwell have both provided ample matter for the story of man during the later Stone and early Bronze ages, and Mr. Home might have drawn upon them more largely with advantage to

[1] "The Evolution of an English Town; being the Story of the Ancient Town of Pickering in Yorkshire." By Gordon Home. Pp. xix+298. (London: J. M. Dent and Co., 1905.) Price 10*s*. 6*d*. net.

his book. A few figures of some of the urns and other relics found by Canon Greenwell in the barrows of the North Riding would have formed more instructive illustrations than the somewhat scrappy and heterogeneous plate of "prehistoric weapons" that faces p. 34. A plate of urns in the Pickering Museum is, indeed, given further on, but it lacks typological qualities. Much has been done during the last few years towards the classification of barrow remains, more especially in the case of the pottery, and there should be no difficulty in presenting a series from so rich a district as Pickering on a plan more in accordance with the results of recent research. In spite of such occasional lapses Mr. Home carries the the reader through the story with considerable skill and vivacity. A later chapter will probably be found the most interesting to the general reader, that dealing with local legends, witchcraft, and folklore. Here there is ample material for a considerable volume, for it is certain that where Mr. Home has gleaned so much there must exist a vast harvest for the trained student. The figure from this chapter reproduced here has been used in sympathetic magic, the universal practice of which Mr. Frazer treats in "The Golden Bough." Traces of Scandinavian importations are frequent, and some of the survivals in local custom have the flavour of a much more remote age. A good deal has already been done in this direction for Cleveland, but it is evidently a fruitful soil and well worth careful and exhaustive treatment. There are some admirable photographic reproductions of the very remarkable, and in some cases beautiful, wall paintings in Pickering Church, and the story of the regulations of the Duchy of Lancaster during Plantagenet and later times is full of quaint customs and interesting matter. The book as a whole has a cheerful air, and may well lead some who are unacquainted with the beauties and interest of Cleveland to pay Pickering a visit.

FIG. 1.—Relic of witchcraft found in the neighbourhood of Pickering. The figure was made of pitch, beeswax, bullock's blood, hog's lard, and fat from a bullock's heart. It was used for casting spells on people, the pin being stuck in the figure where the "ill-cast" was required to fall. From "The Evolution of an English Town."

A few points may be worth the author's consideration if his book should reach a second impression. He seems to be unaware (p. 30) that the Bateman collection of sepulchral urns is now in the museum at Sheffield, and a detailed catalogue was published by the curator in 1899; on p. 45 he states that bronze spearheads have been found in round barrows near Pickering, which seems unlikely; and on p. 48 he figures a quern of a known Roman type in the Bronze age section. On p. 57 an unfortunate slip makes *data* singular instead of plural.

THE GROWTH OF BEET-SUGAR IN ENGLAND.

LORD DENBIGH'S motion in the House of Lords on Monday night, asking for a rebate on the present excise duty on any sugar made in this country from beets during a certain limited period, raises two interesting questions. On one of them the desirability of the State incurring expenditure in order to establish a new industry in the country—we have little to say in these columns; we may be content to point out that it is possible for a Government department to teach the community businesses previously unappreciated. This very beet-sugar manufacture has been introduced into the United States by the action of their Department of Agriculture, with the result that the production has grown to 210,000 tons of sugar in 1904–5 as compared with 20,000 tons ten years earlier.

The other point in dispute is the possibility of growing satisfactory sugar-beet in this country, with its greater rainfall and lower sunshine than the typical Continental centres of sugar production. However, the experiments, organised for so many years by Mr. Sigmund Stein, of Liverpool, and latterly by Lord Denbigh himself, have amply demonstrated that over the east and south-east of England larger crops of sugar-beet can be grown than in Germany without any loss of quality, either as regards the proportion of sugar in the root or its quotient of purity. American experience also shows how adaptable the sugar-beet is to wide diversities of soil and climate.

The English farmer requires but little education in the management of the crop, since the cultivation it requires differs but little from that of the mangel, though the cost per acre is slightly greater. We may take it as settled by numerous experiments extending over many seasons now that the farmer would be prepared to grow sugar-beet in quantity, provided a price were offered approaching that which is paid by the foreign factories, that is, from 16*s*. to 20*s*. per ton of roots. How far the manufacture would be profitable at those rates can only be settled by trial on a commercial scale; a factory must be erected in a suitable district and given a fair working test for two or three years.

While the data available show prospects of a reasonable return on the capital that would be required, one or two difficulties suggest themselves which cannot be resolved except by actual working. The first lies in the provision of labour; the process of manufacture must be practically completed in three months after harvest, and it is doubtful whether labourers could be obtained in this country to work three or four months in the factory and the rest of the time on the land. The other doubtful point is whether the necessary scientific control, for sugar-making from beet is a very specialised piece of chemistry, can be obtained cheaply enough here. Lord Denbigh practically asks the State for a little assistance to get these points settled; with a rebate of the excise duty, equivalent to a bonus of 2*s*. 6*d*. per cwt. on sugar manufactured from beet grown in England, there is a sufficient margin of profit in sight to draw the capital required for the first factory, and a very few years would suffice to demonstrate whether the business would be possible without artificial assistance, or whether the experiment must be dropped.

Without doubt, the establishment of a beet-sugar industry would give the farmer an additional outlet in many parts of the country; it would, however, not work the semi-revolution in agriculture which has resulted from it in many other places. The English farmer already practises intensive agriculture, and the mangel crop, so integral an element in a rotation in the south of England, gives rise to the heavy manuring, the thorough cultivation, and the wealth of food for stock which have been the great benefits conferred by the sugar-beet on the agriculture of Germany and the north of France.

PROF. LIONEL SMITH BEALE, F.R.S.

PROF. LIONEL SMITH BEALE, F.R.S., whose death occurred on March 28 at the age of seventy-eight years, was the son of Mr. Lionel John Beale, and was educated at King's College School and King's College, London. A year after taking his degree in medicine he established a private laboratory in Carey Street, Lincoln's Inn, for pathological, microscopical, and chemical research and teaching; and in 1853, at the early age of twenty-five, was appointed professor of physiology and general and morbid anatomy at King's College. He afterwards held the chair of pathology, and finally that of the principles and practice of medicine at King's College, resigning the latter in 1896. For forty years Prof. Beale was physician to King's College Hospital, and among other honours and appointments received by him during his active career may be mentioned the Baly medal in 1871 for researches in physiology; Croonian lecturer to the Royal Society, 1865; Lumleian lecturer, Royal College of Physicians, London, 1875; president of the Royal Microscopical Society, 1879; and Government medical referee for England, 1891–1904.

As a teacher, Prof. Beale was remarkable for his lucidity; and his lectures were admirably delivered, riveting the attention of his hearers. He had the esteem of all his pupils; and those who had the privilege of a closer intimacy with him feel that they have indeed sustained a great loss by his death.

His principal work, that which gained him the Fellowship of the Royal Society, was on the minute structure of the tissues; "Beale's carmine stain" and his injection mixtures are well known to all microscopists.

Prof. Beale was the author of many works, among the best known being the "Archives of Medicine," containing researches carried out in the laboratory at Carey Street; "How to Work with the Microscope"; "The Microscope in Medicine"; "Protoplasm, Physical Life and Law"; "The Liver"; and "Slight Ailments and their Treatment," besides many papers in the Philosophical Transactions and other publications of learned societies. R. T. H.

NOTES.

The fourteenth "James Forrest" lecture of the Institution of Civil Engineers will be delivered by Mr. R. A. Hadfield on Wednesday, May 2, the subject being "Unsolved Problems in Metallurgy."

The Government of India has decided, with the approval of the Secretary of State, to establish an institute in India as a centre for practical instruction of medical officers and subordinates in the use and management of Röntgen ray apparatus, and as a depôt for the storage and repair of such apparatus. The institute will be located at Dehra Dun, and will be under the superintendence of an officer of the Indian Medical Service.

Prof. R. Meldola, F.R.S., has been made an Officier de l'Instruction publique of France for his services in connection with the foundation of the Alliance Franco-Britannique, of which association he is the honorary secretary.

A Reuter message states that, after perceptible shocks of earthquake, a crevice, out of which lava flowed, opened on the side of Mount Vesuvius, on March 28, some hundred yards from the upper station of the Funicular Railway. The eruption from the principal crater also continues.

At the Meteorological Office Mr. R. G. K. Lempfert has been appointed superintendent of the statistical branch, Mr. Ernest Gold has been selected for appointment as superintendent of the instruments branch, and Mr. J. A. Curtis succeeds Mr. J. S. Harding as cashier and chief clerk.

The Easter excursion of the Geologists' Association will this year be to Lyme Regis. The party will leave London on Thursday, April 12, and return to town on Tuesday, April 17. A detailed itinerary and time-table has been published by the association. The excursion will be directed by Dr. H. B. Woodward, F.R.S., and Mr. G. W. Young, the excursion secretary.

The death is announced of Mr. Carl Heinrich von Siemens. Born in 1829 at Menzendorf, in Mecklenburg, he was the sixth son of a family of fourteen. For the greater part of his life he cooperated with his brothers Werner, William, and Friedrich in the development of the various undertakings with which the name of Siemens is associated. A detailed notice of his career is published in the *Engineer* of March 30.

According to a Laffan telegram from New York, dated March 31, the De Forest Wireless Telegraphy Company has been sending experimental messages from its station at Coney Island to Ireland every night for some time, and on March 28 a thousand words were transmitted, of which 572 were received and recorded. The longest distance that had previously been covered by this company's service was from Coney Island to Colon, 2100 miles; the new record is 3200 miles. The sending stations in Ireland are not yet completed, so that a tetrahedral kite is used temporarily for receiving work.

The following are among the lecture arrangements at the Royal Institution after Easter:—Prof. W. Stirling, three lectures on glands and their products; Dr. P. Chalmers Mitchell, two lectures on the digestive tract in birds and mammals; the Rev. J. P. Mahaffy, two lectures on (1) the expansion of old Greek literature by recent discoveries, (2) the influence of ptolemaic Egypt on Græco-Roman civilisation; Prof. W. J. Sollas, F.R.S., three lectures on man and the Glacial period; and Sir J. Dewar, F.R.S., two lectures on the old and the new chemistry. The Friday evening meetings will be resumed on April 27, when Prof. J. W. Gregory, F.R.S., will deliver a discourse on ore deposits and their distribution in depth. Succeeding discourses will probably be given by the Hon. C. A. Parsons, F.R.S., Prof. J. H. Poynting, F.R.S., Prof. A. Schuster, F.R.S., Mr. L. Hill, F.R.S., Prof. H. Moissan, F.R.S., Sir James Dewar, F.R.S., and others.

In the House of Commons on Monday, Sir W. Foster asked why dead specimens of cancer, preserved in a non-deleterious fluid, have been declared to be forbidden admittance to the post, and why certain specimens, addressed to the Imperial Cancer Research Fund, were ordered to be destroyed immediately on their arrival in this country from abroad. In the course of his reply, Mr. Buxton said:—"The cancer specimens addressed to the Cancer Research Fund are, I am informed on the highest authority, harmless; and, as I am assured that the use of the post is of great importance for the successful prosecution of the researches of the fund, I hope to be able to make a special exception in their favour. I think it desirable, however, that the matter should be discussed with the delegates of the countries principally concerned at the approaching Postal Congress, and I have instructed

the British delegates accordingly. In the meantime, packets addressed to the Cancer Research Fund will be delivered."

The following awards of medals and other honours for this year have just been decided by the council of the Royal Geographical Society:—A Royal (Founder's) medal to M. Grandidier, for the results of his many years' work on the island of Madagascar; a Royal (Patron's) medal to Dr. Robert Bell, F.R.S., director of the Geological Survey of Canada; the Victoria research medal to Prof. W. M. Ramsay, who has been working at ancient geography for many years, and is an acknowledged authority in that branch of study; the Murchison award to Major H. R. Davis, for his explorations in the Shan States, Kachin Hills, Yun-nan, Siam, and Sechuan; the Gill memorial to Major A. St. Hill Gibbons, for the exploring and survey work which he has done in Barotseland on his two expeditions in 1895–6 and in 1898–1900; the Cuthbert Peek fund to Major H. H. Austin, C.M.G., for his exploration in the Lake Rudolf region, the Sobat region, and his expedition from Omdurman to Mombasa *viâ* Lake Rudolf in 1900 and 1901; and the Back bequest to Major R. G. T. Bright, C.M.G., for his exploring work in the Sudan, Uganda, and East Africa.

In vol. vii., article v., of the Bulletin of the Illinois State Laboratory, Mr. F. Smith continues his notes on North American oligochæte worms, dealing in this instance with a species of Lumbriculus.

The report of the Australian Museum, Sydney, for the year ending June, 1905, is before us. The most important addition during the year is a collection of ethnological specimens from North Queensland made by Dr. W. A. Roth, protector of aborigines for that district.

In contrasting different statements as to the purpose and function of museums, the March issue of *Museum News* (Brooklyn, N.Y.) takes occasion to rebuke the "Century Dictionary" for employing the word "curiosities" in this connection, the accumulation of "curiosities" being exactly what every curator who knows his business does his best to avoid.

The thirty-fourth number of the publications (they have no general title) of the Bureau of Government Laboratories at Manila is devoted to an account of birds from Mindoro and the adjacent islets, and to notes on three birds of rare occurrence in Luzon, one of these latter being the bittern. The first paper, which is well illustrated, contains descriptions of several new species, among them being a needle-tailed swift.

A fuller account of the Black Hills beetle (*Dendroctonus ponderosae*), a scolytid infesting pine-trees in the Black Hills of South Dakota and elsewhere, described by the author some time ago, is given by Dr. A. D. Hopkins in Entomological Bulletin No. 56 of the U.S. Department of Agriculture. The serious nature of the damage caused by this beetle is indicated by the statement that between 700 and 1000 million cubic feet of timber have been destroyed by it in the Black Hills Forest Reserve alone.

The third part of the *Bergen's Museum Aarbog* for 1905, of which we have received a copy, contains a long and fully illustrated paper by Mr. O. J. Lie-Pettersen on the marine rotifers of Norway, the result of investigations commenced in the summer of 1900, and a second by Mr. H. Brock on Norwegian medusas. The two last papers in this part are devoted to archæological subjects. We have also received a copy of the *Aarsberetning* of the same institution, containing the director's report of progress for the past year.

Part iii. of the third volume of the Transactions of the Hull Scientific and Field Naturalists' Club shows careful attention on the part of that body to local subjects. The first article, for instance, deals with the natural aspects of Hull and its neighbourhood; and others are devoted to the East Riding Mycetozoa, local diatoms, and reclaimed lands of the Humber district. Two local celebrities are accorded biographical notices, with portraits, while the editor, Mr. T. Sheppard, discusses the position of the Hull Museum as regards education.

The papers in the March *Zoologist* comprise one on the birds of the Færöes, and a second on those of Anglesey; while in a third Mr. R. Warren records a change in the habits of herrings visiting Killala Bay, county Mayo. It appears that since 1899 the fish, which used to keep to the bay, have taken, for about three weeks in the autumn, to entering the estuary and tidal part of the river. So close have they on some occasions come in-shore that scores may be taken with a landing-net.

The contents of the first part of vol. lxxxi. of the *Zeitschrift für wissenschaftliche Zoologie* comprise one paper by Mr. W. Schimkewitsch, of St. Petersburg, on the developmental history of the arachnid *Thelyphonus caudatus*, and its comparison with that of other members of the same group. In a second paper Mr. R. Meyer discusses the histology of the nervous system of the common starfish, *Asterias rubens*, while in the third Mr. O. Kohlmeyer describes the elastic tissue in the mucous membrane of the palate of the brown rat, the distribution of which has never previously been worked out.

An extinct volcano in Arizona and its crater form the subject of a paper by Mr. D. M. Barbinger in the issue of the Proceedings of the Philadelphia Academy for December last. One of the most remarkable features connected with this mountain is the presence of an enormous mass of meteoric iron. As the result of his investigations, the author comes to the conclusion that a huge meteor, of which at least the outer coat was metallic, fell to the earth in this locality, and that its size was so great that portions of it were fused and detached. Further, a large hole in the adjacent strata was made by the fall of the meteor.

Dr. W. J. Holland has sent us a paper on the osteology of the American dinosaur Diplodocus, with special reference to the model of the skeleton presented by Mr. Carnegie to the Natural History Museum, and installed by Dr. Holland himself. In this paper, which forms No. 6 of the second volume of the Memoirs of the Carnegie Museum, the author directs attention to the pose in which the skeleton has been mounted, explaining that, in his opinion, the peculiar structure of the occipital region renders the angle which the skull forms with the vertebral column a matter of necessity. Dr. Holland finds himself unable to accept Baron Nopsca's interpretation of the nature of the problematical bone which has been regarded as a clavicle.

The black locust tree (*Robinia pseudo acacia*) is such a familiar inhabitant of railway banks, especially in parts of France, that we read with interest Dr. Charles A. White's account, in the *Popular Science Monthly* for

March, on the troubles which have beset attempts to establish it in similar situations in America, especially in Pennsylvania. The wood of the tree is excellently suited for making fence posts and railroad ties, but, unfortunately, as soon as the stems attain a sufficient size to be of use they are liable to be destroyed by the burrowing larvæ of a longicorn beetle (*Cyllene robiniae*); and so persistent is this beetle in its attacks, that Dr. White considers the further planting of these trees to be sheer waste of labour and money.

The second number of the *Bio-Chemical Journal* contains four papers of considerable interest, and if the present standard be maintained we predict a long and useful "life" for this new publication. Mr. Leonard Hill discusses filtration as a possible mechanism in the living organism, and concludes that it does not occur under natural conditions; Mr. G. S. Haynes, writing on the pharmacological action of digitalis, strophanthus, and squill on the heart, considers that it is essential that these drugs should be standardised, as the amounts of active constituents vary much. He finds that strophanthus is 8 to 10 times as toxic as digitalis, and that squill is an excellent cardiac stimulant. Dr. Roaf and Mr. Whitley contribute a paper on the action of acids, alkalies, and salts on the tadpole; and Dr. MacLean details observations on the Fehling test for dextrose in urine, proving that creatinin is the cause of the masking of the sugar reaction which sometimes occurs in urine-testing.

A brief description appears in the Journal of the Royal Microscopical Society (February) of a newly discovered synangium that, as the writer, Mr. D. M. S. Watson, states, would two years ago certainly have been regarded as the fructification of a marattiaceous fern. The synangium consists of from four to seven sporangia grouped round a central receptacle that is hollowed out into a cup at the top, thus bearing considerable resemblance to the sporangia of the recent fern Kaulfussia and of the fossil species *Ptychocarpus unitus*. Having regard to Mr. Kidston's discovery that the synangium of Crossotheca, formerly considered to be that of a marattiaceous fern, was the male fructification of Lyginodendron, Mr. Watson leaves it open whether the new species, *Cyathotrachus altus*, should be placed in the ferns or cycadofilices.

In connection with the work of the instructors in horticulture that have been appointed by certain county councils in Ireland, it has been found that there is need of a scientific journal that will help to supply the knowledge required by small farmers and occupiers of holdings. To meet this want a new monthly publication, *Irish Gardening*, has been started, the first number having been issued this month. After a short note of encouragement from Sir Horace Plunkett, Mr. F. W. Moore provides an appropriate article on the present condition of horticulture in Ireland. The use and value of horticultural demonstration plots is discussed by Mr. J. G. Toner, and a trite comparison of English and Irish potatoes is contributed by Prof. J. Wilson in which, while upholding the quality of the Irish potato, he suggests that there is scope for new Irish varieties. Judging from these articles and the numerous notes on various topics, the new journal promises to fulfil its purpose of directing attention to the scientific principles that underlie good garden practice.

The discussion on "The Origin of Gymnosperms" at the Linnean Society, arranged for the meeting on March 15, drew a very large audience. Prof. F. W. Oliver, in opening the discussion, referred to the generally accepted view that the line of descent of the gymnosperms had proceeded through the ferns and cycads, this view being supported by the discovery of multiciliate spermatozoids in Ginkgo and in cycads, and by the recognition of the fossil group of cycadofilices. The discovery of seeds in connection with several of the Palæozoic "ferns" had led to their transference to a new and rapidly increasing group of pteridosperms. If the Palæozoic were an "age of pteridosperms" rather than an "age of ferns," was the filicinean origin of the gymnosperms weakened, and should a lycopodiaceous origin be sought? Personally, he favoured a derivation of the pteridosperms and eventually the cycads and Cordaiteæ from the ferns. Mr. E. A. N. Arber, dealing with the earlier geological records of the true ferns, also expressed his adherence to the fern-cycad line of descent. He instanced the Botryopterideæ as true ferns existing in the Carboniferous and Permian ages, and pointed out that the connection of gymnosperms and ferns must have been far back in the Palæozoic epoch. Prof. A. C. Seward, while accepting the filicinean origin for the cycads, dissented from the view that the conifers followed the same line of descent. His recent investigations of the Araucarieæ pointed to their being a very ancient group of gymnosperms, and for them, if not for conifers generally, he considered a lycopodiaceous derivation as the more probable. Owing to the late hour, Dr. D. H. Scott was unable to give his address, as announced, so the proceedings were postponed to the meeting fixed for May 3, when an opportunity will be afforded for other members to take part in the discussion.

The work of the expedition dispatched by the Smithsonian Institution of Washington to the Canadian Rockies and Selkirks, under the direction of Prof. W. H. Sherzer, of the Michigan State Normal School, is described in the report of the late Dr. S. P. Langley for the year ending June 30, 1905. The expedition had a successful season's work on the glaciers along the line of the Canadian Pacific Railway. A selection was made of those five glaciers which are most accessible to the student of glacial geology, and these were found to exhibit the characteristics of glaciers throughout the world. Four or five days of comfortable railway travel places an investigator in the midst of snow-fields rivalling those of Switzerland, and the ice bodies descending from these fields may be studied from modern hotels as a base, and a horse may be ridden to the feet of the glaciers studied by the expedition. So far as is known, there is in this district the most magnificent development of glaciers of the Alpine type on the American continent, and the purpose of the survey was to gather as much information as possible concerning them. Many photographs illustrating the details of glacial structure were obtained, and a full report of the expedition may be expected later.

We have received a copy of the results of the meteorological observations made at stations under the control of the Deutsche Seewarte for the year 1904. These observations include those made at ten stations of the second order, at which readings are taken three times daily; at four of these stations, viz. Hamburg, Wustrow, Memel, and Borkum, hourly values and means obtained from self-recording instruments are given in addition. For all days on which stormy weather was experienced on the German coasts, observations for several times a day are published from those of the fifty-six storm signal stations affected. This valuable publication forms one of the series of "Meteorological Year-books" issued by the various organisations

of the German Empire; these are all identical in form, the plan of which is practically that adopted by the International Meteorological Congress at Rome in 1879, and leaves nothing to be desired. With the exception of an occasional improvement, such as the reduction of the old anemometrical factor, which assumed that the velocity of the wind was three times as great as the velocity of the cups of the instrument, and the addition of a table showing for each station the difference between local time and mid-European time adopted in Germany in April, 1893, there has been practically no change in the contents of publication for many years. This continuity of form is a great advantage, and considerably enhances the value of the work.

We have received from the director of the Vatican Observatory, Sig. P. Angelo Rodriguez, O.S.A., vol. vii. of the *Pubblicazioni della Specola Vaticana* (Tipografia Vaticana, Rome, 1905). In these pages we first have the individual daily meteorological observations made during the years 1902 to 1904, both years inclusive. These are graphically plotted in three tables which are given at the end of the volume. Sig. Mg. Alfredo Tonetti contributes a valuable study of the cloud observations made during the years 1891–6, and this is followed by two appendices, which include observations of meteors for the years 1891 to 1896, and the mean monthly values of cloudiness for the same period. Among other sections of interest may be mentioned a brief discussion of the exceptional high temperatures recorded in July and August of the year 1904, comparison data being added commencing in 1890. Sunspot observations are also dealt with, and, in addition to the individual daily observations, a summary for each year, commencing with 1896, is added. Special reference is made to the large spot of February, 1905, and a reproduction (original size) of the solar disc for February 7 is added, the original photographic image measuring nearly eleven inches in diameter.

In the Transactions of the Institution of Engineers and Shipbuilders in Scotland (vol. xlix., part v.), Mr. W. A. Ker publishes a suggestive paper on some common errors in the use of electric motors for machine driving. In it he gives a list of common machines, with the types of motors which he considers most suitable for them.

Attention is directed in the *Engineering and Mining Journal* (vol. lxxxi., No. 10) to the very low cost of ore dressing which has been attained at the mill of the Osceola Copper Mine, Lake Superior. The average cost per ton of rock stamped in 1905 was only $8\frac{1}{2}d.$, as against $9d.$ in 1904. These extraordinary figures were obtained in the treatment of a million tons of rock per annum, all the ore passed through the mill having been crushed to go through a $\frac{1}{4}$-inch to 3/16-inch round hole.

The locomotive industry is dealt with in an exhaustive paper by Mr. L. Le Chatelier in the *Bulletin de la Société d'Encouragement* (vol. cviii., No. 2). Beginning with Trevithick's locomotive of 1803, he illustrates the leading types, and expresses the opinion that the works of the Hanover Engineering Company represent the most perfect example of the international locomotive industry. The Crewe works, with their 7500 workmen and their annual output of seventy-five locomotives, are referred to by the author in terms of warm admiration.

"Economic Studies in Italy" form the subject of a letter by Prof. Achille Loria in the *Economic Journal* for March. A noteworthy feature of Italian economics is the absence of any scientific treatment of socialistic problems.

In the Bulletin of the Belgian Royal Academy (1905, xi.), the death is announced of the oldest member, M. Gustave Davalque, who was elected associate in 1854 and member in 1859, and drew up reports on mineralogy for the society subsequent to 1872.

Prof. Luigi Berzolari contributes to the *Rendiconti* of the Lombardy Institution an interesting account, extending to more than sixty pages, of the work of the late Prof. Luigi Cremona. A list of previous biographical notices is given in a footnote.

Prof. G. Cesàro, of Liége, describes in the Bulletin of the Belgian Academy, x., a new method of proving geometrically the principal formulæ of spherical trigonometry, notably Lhuilier's and Euler's formulæ, Napier's and Delambre's analogies, and the expressions for the radii of the circles of a triangle.

Mr. H. M. Taylor, F.R.S., has published in the *Messenger of Mathematics*, No. 414, a collection of geometrical dissections, in which it is shown how to transform figures from one shape into another by division into a definite number of parts and re-arrangement of the parts. While these constructions afford a highly interesting study, it may be desirable to point out that if it be required, for example, to convert a rectangle into a square of equal area by this method, the construction presupposes a knowledge of the side of the required square.

In the Bulletin of the American Mathematical Society for January Prof. Jacques Hadamard gives a review in French of the late Prof. Willard Gibbs's "Elements of Statistical Mechanics," which appeared in 1902. Based as the review is on a detailed study of Gibbs's work and of criticisms thereon, the notice forms in some respects an innovation in reviewing which might with advantage be followed on other occasions in connection with mathematical works. It is certain that the book in question contained many features that could only be properly judged after long and minute study.

In a paper reprinted from the *Abhandlungen* of the Royal Academy of Saxony, xxix., 4, Dr. Otto Fischer discusses the dynamics of the motion of a system of bodies jointed together and moving in space. An illustration of such jointed systems is afforded by the limbs of animals. In general, a system of n jointed bodies has $3n+3$ degrees of freedom, but there are many cases in which the number is less, and the author shows how the equations can be simplified by replacing the system by a dynamically equivalent set of particles or "reduced system."

Under the title "Abhandlung zur Didaktik und Philosophie der Naturwissenschaft," Messrs. Julius Springer, of Berlin, are issuing a series of pamphlets, in the form of monograph supplements to the *Zeitschrift fur den physikalischen und chemischen Unterricht*. The object of these pamphlets is to give expositions of various points connected with the teaching of the sciences in question. No. 5 of the series is by Prof. Hans Keferstein, of Hamburg, and contains an exposition of the elementary properties of lenses and optical combinations treated from an experimental point of view. In the introduction the author points out that two of the various branches of physics, mechanics and optics, are made to assume a more mathematical aspect than the rest, the former by introducing the concept of particles, which reduces the study to that of certain systems of *points*, the latter by the concept of rays, leading to the study of certain systems of *lines*. The

present pamphlet treats exclusively of the magnifications produced by lenses, the paths of the rays, and the principles of the microscope and telescope.

The danger which may accompany the teaching of elementary chemistry to children has been sadly illustrated by the death of a girl of fifteen years of age—a pupil at the Plymouth Secondary School—caused by swallowing a strong solution of caustic soda while working in a practical chemistry class. The coroner's inquest showed that the child—one of a class of eight—misinterpreted the directions given by the instructor, and sucked into a pipette a concentrated solution of the alkali without previously diluting it, as she had been told to do; in doing this she managed to swallow some of the solution. In view of the fact that three other pupils out of the eight in the class gave evidence showing that they also had not followed the directions given, it is clear that, in order to guard against such accidents, the experiments should be devised in such a way that, in the event of a misunderstanding, no evil results may accrue. In the present case, for instance, in which the neutralisation of sulphuric acid by caustic soda was being studied, the concentrated solutions might have been diluted by the demonstrator in front of the class, and the diluted solutions thus prepared then have been used for the pupils' measurements. Other simple expedients could readily be suggested in which the use of an ordinary pipette is avoided. In the practical study of chemistry there are many possibilities of accident, and this should be borne in mind by the examining and inspecting authorities which prescribe the work to be done in school laboratories, and by the teachers who devise experiments for their pupils. It should be unnecessary to add that the instructor, particularly when he has to deal with children, should not only have seen chemical experiments performed, but have acquired by a prolonged course of laboratory work a real knowledge of manipulation and of the dangers likely to be incurred in any case.

Messrs. John J. Griffin and Sons, Ltd., have issued a third edition of their well illustrated list of apparatus for electrochemistry, arranged for students working through Dr. Lüpke's "Grundzüge der Electrochemie."

A popular article, with several striking illustrations, upon the eye-spots exhibited by various creatures as ornaments or for protective purposes appears in the April number of *Pearson's Magazine*.

The current issue of the *Home Counties Magazine* contains, among other interesting matter, a reprint of a lecture by Mr. M. J. C. Meiklejohn on the place-names of Northwood and district, and the first of a series of articles in which the editor, Mr. W. Paley Baildon, has collected all available references to Paul's Cross, and arranged them in chronological order.

The current number of *Past and Present*, the successor to the *Natural History Journal*, published in connection with the Friends' Schools, is before us. The magazine shows that great encouragement is given in these schools to observational science, and that the boys are in the habit of making and recording outdoor observations in biological and meteorological science. The illustrations of the school buildings are proof enough that the claims of science are not forgotten in the school curriculum.

Several parts of volumes of Transactions of the Royal Society of Edinburgh, containing papers read before the society during the sessions 1902–3, 1903–4, and 1904–5, have just been received; and also vol. xliii. of the Transactions, edited by Dr. A. Buchan, F.R.S., and Mr. R. T. Omond, devoted to the Ben Nevis observations during the years 1893–7. As abstracts of the papers read before the society appear periodically among our reports of meetings, it is unnecessary to refer again to the many important contributions now printed in full in the Transactions recently issued.

The fifth part of vol. ii. of the Proceedings of the University of Durham Philosophical Society has been received. The number contains five papers read before the society between February 9 and April 27, 1905, together with the proceedings for the academic year 1904–5. Prof. H. Stroud contributes a paper on spark-gap experiments for detecting radio-activity, Dr. J. A. Smythe a note on a contact rock from the Island of Mull, Mr. A. Brennan notes on abnormal flowers of *Lilium Martagon* (Linn.), Dr. D. Woolacott a paper on the pre-Glacial "wash" of the Northumberland and Durham coalfield, and Mr. G. Thomson one on the effect of light on selenium.

OUR ASTRONOMICAL COLUMN.

Astronomical Occurrences in April:—

April 5. 5h. 48m. to 6h. 42m. Moon occults α Leonis (Regulus, mag. 1·3).
6. 7h. 3m to 7h. 57m. Moon occults χ Leonis (mag. 4·7).
,, 15h. 50m. to 16h. 19m. Moon occults σ Leonis (mag. 4·1).
11. 11h. 30m. Minimum of Algol (β Persei).
14. 8h. 19m. ,, ,, ,,
15. Venus. Illuminated portion of disc = 0·967. Of Mars = 0·978.
16. 15h 48m. to 16h. 29m. Moon occults θ Capricorni (mag. 4·2).
18. 23h. Saturn in conjunction with Moon. Saturn 0° 22′ N.
24. 8h. 22m. Transit (ingress) of Jupiter's Satellite III. (Ganymede).
,, 15h. Venus in conjunction with Moon. Venus 5° 11′ N.
26. 4h. Jupiter in conjunction with Moon. Jupiter 4° 16′ N.
,, 5h. 42m. Near approach of Moon to α Tauri (Aldebaran).
27. 8h. 51m. to 9h. 48m. Moon occults 119 Tauri (mag. 4·6).
30. 11h. 33m. to 12h. 28m. Moon occults ζ Cancri (mag. 4·7).

Comet 1906*b*.—A part of the ephemeris for comet 1906*b* (Kopff), calculated by Herr M. Ebell and published in No. 4080 of the *Astronomische Nachrichten*, is given below:—

Ephemeris 12h. M.T. Berlin.

1906	α (true) h. m. s.	δ (true) ° ′	log r	log Δ	Brightness
April 6	11 22 53	2 24	0·5355	0·3983	0·81
14	11 21 18	2 28	0·5397	0·4128	0·74
22	11 20 38	2 26	0·5440	0·4291	0·67
30	11 20 58	2 20	0·5484	0·4468	0·61

Unit brightness on March 3 = about mag. 11·0.

This comet is still in the constellation Leo, near to the star τ, which is on the meridian at about 11 p.m.

The suggestion that this object was a periodic comet of short period is not confirmed by the observations.

Observing at Strassburg on March 17, Dr. Wirtz recorded that the comet had a nucleus of mag. 11·5, the total magnitude being 11·0. The nebulosity was only 0′·7 in diameter, and appeared to be extended towards position angle 270°.

Comet 1905*c*.—The following is an extract from Herr Wedemeyer's ephemeris for comet 1905*c* (Giacobini) as published in the supplement to No. 4080 of the *Astronomische Nachrichten*:—

Ephemeris 12h. M.T. Berlin.

1906	α (true) h. m. s.	δ (true) ° ′	log *r*	log Δ	Brightness
April 5	3 36 46	+ 8 12	0·2390	0·3763	0·20
9	3 45 22	+ 9 8	0·2559	0·3943	0·17
13	3 53 33	+ 9 59	0·2718	0·4114	0·15
17	4 1 22	+ 10 46	0·2870	0·4275	0·13
21	4 8 53	+ 11 28	0·3014	0·4428	0·11

An observation at Strassburg on March 17 gave corrections of −11s. and −3′·9 to this ephemeris. The comet was pale, with no certain nucleus, and the ill-defined nebulosity was about 2′ in diameter; total magnitude about 11·5.

This faint object is now apparently traversing the constellation Taurus towards the Pleiades, and will be some 3° south of that asterism on April 23. It sets, a little to the N. of W., at about 9 p.m.

A Systematic Study of Faint Stars.—Apropos of Prof. Kapteyn's plan for studying faint stars, Prof. Pickering gives a detailed account of how similar work is being performed at Harvard College Observatory in *Circular* No. 108.

It is impossible to describe the whole work here, but both photometric and photographic methods are being employed, and by using the two 24-inch reflectors Prof. Pickering hopes to extend the survey to stars fainter than Phœbe.

In studying the spectra, the 8-inch Draper and Bache telescopes have been employed, and stars down to the eleventh magnitude have been observed successfully. Using the 24-inch reflectors, Prof. Pickering hopes to photograph the spectra of much fainter stars.

By following the stars precisely, so that the resulting spectrum is merely a line, thirteenth magnitude stars have been dealt with, and, on a photograph obtained with the 8-inch Draper telescope, the spectrum of a star of mag. 13·3 is sufficiently clear to be classified; the same plate shows the spectra of 110 stars within 1° of the North Pole.

Stars having Peculiar Spectra.—In *Circular* No. 111 of the Harvard College Observatory, Prof. Pickering gives a list and details of twenty-four stars which, from a study of the Henry Draper memorial photographs, Mrs. Fleming has found to have "peculiar" spectra.

One or two of the objects call for special remark. The star D.M. +21° 1609 is identical with N.G.C. 2392, which was found to have a continuous spectrum, with three bright lines, by Wenlock and Peirce on January 7, 1869. D'Arrest, also, found it to be gaseous. Photographs taken at Harvard on November 21, 1900, and November 27, 1905, show no traces of the bright lines characteristic of gaseous nebulæ, but that its spectrum is of the fourth type. This star is in Gemini, its approximate right ascension and declination (for 1900) being 7h. 23·3m. and +21° 7′ respectively.

In the spectrum of the star D.M. +36° 3907 the hydrogen line Hβ appears as a fine bright line centrally superposed on a dark line, on photographs taken on July 4 and November 4, 1905.

A spectrogram of the variable star R Cygni, obtained on November 19, 1890, showed the hydrogen lines Hγ and Hδ bright, but a photograph taken on December 7, 1904, with the same instrument, shows a spectrum of the fourth type containing no trace of bright hydrogen lines.

The Lunar Eclipse of February 8.—The total eclipse of the moon which took place on February 8 this year was fully observed at the Goodsell Observatory, Northfield, Minn. (U.S.A.), and an account of the observations is given in No. 3, vol. xiv., of *Popular Astronomy*.

Dr. Wilson especially remarks on the brightness of the eclipsed moon, and on the remarkable contrasts of colour seen on the darkened surface.

Five photographs were secured, and the last one, taken with a small camera attached to the telescope, exposure 5m., shows the details of the lunar surface and its unequal colouring very plainly.

Similar observations were made by M. Quénisset at the Nanterre Observatory, and four of his photographs are reproduced in the March number of the *Bulletin de la Société astronomique de France*. He records the shadow as "very transparent."

PARALLEL RUNNING OF ALTERNATE CURRENT GENERATORS.

The *Bulletin des Séances de la Société française de Physique* for the second quarter of last year contains an interesting article by M. Boucherot on the general principles which enter into the design and construction of alternating current generators.

After a brief description of the present methods of construction, the author passes on to consider, first, the wave form; secondly, the regulation; thirdly, parallel running; and, finally, methods of compounding.

The most important part of the article is that devoted to the question of parallel running, and, although the mathematical treatment is not very clearly explained, the conclusions arrived at are interesting.

The question is considered under two headings. In each the subject of inquiry is the influence of the fly-wheel, or the fly-wheel effect of the rotating parts, on the oscillations about a state of uniform angular velocity; but under the first heading the oscillations are caused by the variations of turning effort of the prime mover during a single revolution, and under the second heading the oscillations are produced by the action of the engine governor.

In dealing with the first of these there are two quantities which are of prime importance in the calculations viz. the energy stored in the rotating parts, $W(=\frac{1}{2}J\Omega^2)$, and the elastic couple or restoring force, C_s, which is defined as the couple which tends to restore the rotating parts to phase coincidence with the network to which the armature is connected, when the deviation is one radian. Then it is shown that the natural period of the system is $2\pi\sqrt{J/C_s}$, and the restoring force $C_s = C_N pk$, where C_N is the full load torque, p the number of pairs of poles, and k the ratio of the short-circuit current to the normal current.

Next, the analysis of the turning moment is given for single-cylinder and for multiple-cylinder engines as follows:—

	Order of harmonic	Half load	Full load
Single cylinder	1	0·12	0·14
,, ,,	2	0·9	0·9
,, ,,	3	0·12	0·11
,, ,,	4	0·4	0·11
Multiple cylinder	1	0·1	0·1
,, ,,	2	0·5	0·2
,, ,,	3	0·35	0·15
,, ,,	4	0·4	0·4

the mean constant turning moment being reckoned as unity.

Each harmonic produces its own oscillation in the rotating system, the amplitude of which is proportional to the value of the harmonic multiplied by $\frac{1/2n^2}{W-W_n}$ (not $W/W-W_n$ as stated in the original), where n is the order of the harmonic and $W_n = C_s\, 2n^2$. If the total fly-wheel effect happens to be such that $W=W_n$, resonance will occur, and this expression will enable the designer to proportion the rotating parts so as to avoid serious trouble.

More interesting is that part of the article devoted to the effect of the engine governor on parallel running and hunting. The subject is confessedly a difficult one, and at present there is no accepted theory. The suggestion put forward by the author is somewhat compressed and difficult to follow; and, even so, only the chief points of the argument can be mentioned here.

The generating set with its governor is treated as being composed of two interdependent oscillating systems, each with its own natural period and its own coefficient of damping. In addition to these four quantities, two others are of great importance, viz. K, the percentage variation of speed between no load and full load, and T_a, the time lag of the governor. The latter quantity is defined as the time which elapses between the governor reaching its extreme position and the turning moment of the engine taking up its corresponding value. This time lag is greater in compound and triple expansion than in simple engines, due to the passage of the steam through the cylinders.

Considering, first, the case of a generating set connected to an external network assumed to be of infinite capacity, it

is shown that the periodicity of the oscillation is given by the equation

$$\tan(\alpha . T_d) = 1/2m(\alpha_r/\alpha - \alpha/\alpha_r),$$

where $2\pi/\alpha$ is the period of the oscillations produced, $2\pi/\alpha_r$ is the natural period of the governor, and m is the

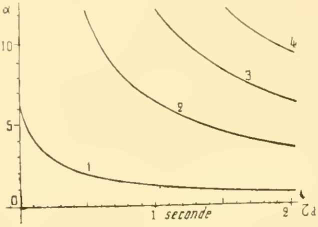

Fig. 1.

ratio of the actual damping of the governor to the smallest value of the same coefficient which makes the governor dead beat.

This equation of α in terms of T_d represents a series of curves, some of which give rise to negative values. The positive values corresponding to $m=1$ and $\alpha_r=6{\cdot}32$ are

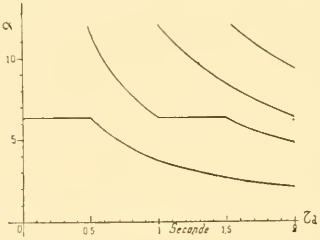

Fig. 2.

shown in Fig. 1. Of these curves, only the lowest one represents oscillations which are not evanescent.

For this case the conclusion is reached that for satisfactory running the percentage variation of speed K must not be too small, and the fly-wheel effect must be designed in proportion to the time lag of the governor.

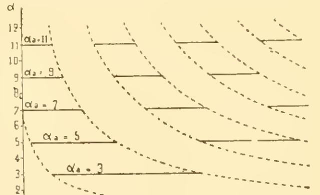

Fig. 3.

Passing to the case where two sets are working in parallel, the equation giving the frequency of the oscillations is similar to the above, provided the damping in the generators is small. In this case, however, the curves which give positive values of α are quite different, being as shown in Fig. 2. The straight line portions correspond to $\alpha=\alpha_a$, where $2\pi/\alpha_a$ is the natural period of the alternator.

Now the rate of subsidence of any oscillation contains a term $(1-\alpha/\alpha_a)$, and it is consequently clear that it would be unsafe to allow any value of T_d between 0 and 0·5, or between 1 and 1·5, as shown in the figure. If, however, the damping of the governor is much greater than the critical dead-beat value, satisfactory working may be possible.

A point of great interest is brought out in this connection, viz. the influence of the fly-wheel effect. The straight portions of the curves in Fig. 2 depend upon the natural period of the alternator, which in turn depends upon the fly-wheel. The heavier the fly-wheel the less the value of α_a, and consequently the longer the straight portion of the curve as shown in Fig. 3. In other words, the greater the fly-wheel effect the greater will be the range of T_d for which satisfactory working is difficult. From this it would appear that it is quite possible to provide too heavy a fly-wheel.

The article concludes with a brief reference to the various methods of compounding alternators.

GEOLOGICAL NOTES.

In the *Zeitschrift der Gesellschaft fur Erdkunde zu Berlin* (1905, p. 412) Prof. Dr. A. Phillipson, of Bern, outlines his recent journey of 10,000 kilometres through the west of Asia Minor, including Brussa, near the Sea of Marmora, and Makri, on its Mediterranean inlet in the south. The preliminary results indicate the existence of a "Lydian mass" of granite, gneiss, and crystalline schists, which forms on the whole a hummocky country, flattening itself out where the lower course of the Mæander cuts into it. The inhabitants are mostly clustered along the included basins of Neogene deposits. A zone of metamorphic limestones and less altered phyllites lies outside this mass, following the strike of the bow-shaped crystalline core; and the discovery of a new species of Fusulina (p. 417) places part of this outer zone as Permo-Carboniferous. To the south and south-east, the Cainozoic earth-movements have brought up folded limestones of the Cretaceous and Eocene type of Greece and Rhodes. The complete results of the journey will not be worked out for several years.

Dr. G. Steinmann continues, in the *Berichte der naturforschenden Gesellschaft zu Freiburg-im-Breisgau* for September, 1905, his "Geologische Beobachtungen in den Alpen." The question of Klippen-structure and overfolding in the classical Alps of Glarus leads on to a comparison with the eastern Alps. The author gives a valuable exposition of Schardt's views, which were published in 1893, and which led to the conception of the breaking up of an overthrust limestone mass into blocks or "klippen," which lie discordantly among later sediments. Without going so far as Termier (p. 32), Dr. Steinmann sees in this striking theory of overfolding the true explanation of the phenomena of the Bündnerschiefer and the limestone zone, and he appeals to workers in the eastern Alps to consider Schardt's views at least in the light of a scientific possibility. The last part of the present paper includes a bold but reasonable speculation as to the connection between deep-sea radiolarian deposits and diabasic igneous rocks. It is suggested, for the Alpine, Scotch, and other instances, that these basic igneous masses accumulated under the ocean-floors, just as more highly silicated rocks are believed to gather under continents. Consequently, a deep-sea epoch, followed by one of compression and overthrusting, would lead to a squeezing out of "ophiolitic" igneous rocks somewhere along the zone of the radiolarian cherts.

The activity of geological research in the African colonies is evidenced by a recent part of the *Transactions of the Geological Society of South Africa*, published in Johannesburg in September, 1905. Mr. A. L. Hall describes (p. 47) the mode of occurrence of the tin-ore in the picturesque Bushveld area forty miles north-east of Pretoria. The ore was first noticed in the local granite as recently as 1904, and the field was described by H. Merensky in that year. Its exploitation at once followed, and Mr.

Hall has been able to examine the rocks traversed by the new shafts and drives. The field was extended, while his paper was in preparation, by a further discovery on the farm Vlaklaagte. In this case there is evidence of the deposition of the cassiterite in good crystals, of the size of coarse shot, throughout a granitoid rock, which is of later age than the surrounding red granite. Minerals containing fluorine, topaz being among them, are already known in the Bushveld igneous series, and hence there is reason to believe that the tin-ore may have been developed on Enkeldorn and Vlaklaagte in the manner recognised in the "classical stanniferous localities."

Mr. H. Kynaston appropriately describes (*ibid.*, p. 61) rocks allied to greisen, from a point much further north, in the Olifants River Valley. He also adds to our knowledge of the norites and schists associated with the Bushveld granite, perhaps as marginal phenomena. Dr. Molengraaff, whom we regard almost as a veteran in these years of rapid exploration, and as the founder of much of our knowledge of the Transvaal, further supports his view (*ibid.*, p. 63) that the Pretoria series may be correlated with the jasper beds of Griqualand West. He now describes Mr. Leslie's discovery of crocidolite in the ferruginous quartzites of the Pretoria series in the Lydenburg district. These beds overlie the well known dolomite, which thus may be paralleled with the Campbell Rand dolomite of the south. Dr. Molengraaff's account of contact-altered rocks in the Pretoria series should fit in with Mr. Kynaston's observations further north; and the conferences of the Geological Society of South Africa will doubtless show how much of the extensive alteration is due to the granite and felsite series, and how much to the sheets of norite. The present tendency, however, seems to be towards the linking of these two types of intrusive rock in a continuous series.

Mr. Thord-Gray (*ibid.*, p. 66) describes in some detail the occurrences of gold in the Pretoria series round Pilgrim's Rest (Lydenburg gold-field), and concludes in favour of the view that a mineral infiltration, carrying both gold and copper, took place along certain zones of the conformably bedded series. The horizontal "reefs" may thus be described as altered quartzites.

The correlation of the members of the Transvaal system is again taken up by Prof. Schwarz, who attacks the problem in the north of Cape Colony, in Prieska. He has, quite independently, reached the same conclusions as Dr. Molengraaff, and, with certain cautious reservations, passes his comprehensive eye over similar beds in India and North America also. The extraordinary uniformity of deposits in South Africa across enormous areas certainly gives one a new faith in lithological stratigraphy; and it is on this ground that Prof. Schwarz wishes to bring together the two series of ferruginous jaspers in the southern part of the Transvaal, calling in a thrust-plane to his assistance. The general feeling will be, both in our islands and in the Transvaal, that detailed mapping will ultimately bring a just correlation in its train. But detailed geological mapping requires good topographic maps, and the limited resources of the colony seem just now, from a legislator's point of view, to have many prior claims upon them.

Mr. F. P. Mennell shares with the equally energetic Mr. A. J. C. Molyneux the task of elucidating the geological problems of Rhodesia, a region about as large as France, Germany, Austria-Hungary, and Italy put together. The gold problem is naturally the first thing to be investigated, and Mr. Mennell (*ibid.*, p. 82) seeks to correlate the Rhodesian "banket," which he shows to be a true conglomerate, with the gold-bearing series of the Rand at Johannesburg. "So far," however, "it is only at the Eldorado Mine, in the Lomagundi district, that gold has been proved to exist in payable quantities" in the banket of Rhodesia. As Prof. J. W. Gregory recently informed us, other deposits or vein-stuffs may have become known as banket, and it is certainly wise to restrict this term, of Transvaal origin, to the quartzose conglomerates, wherever they occur. In Rhodesia, Mr. Mennell has to deal with a metamorphosed series of sediments, including these conglomerates, and penetrated by ancient and now schistose basic rocks. The widely occurring granite is later than the basic intrusions, and has produced considerable contact-alteration in the entire series. The gold, in accordance with the view now prevalent for the Rand deposits also, is regarded as a subsequent infiltration.

Part ii. of vol. xxxii. of the *Records of the Geological Survey of India* contains Mr. Hayden's "Preliminary Note on the Geology of Tibet," already noticed in this Journal (Nature, vol. lxxii., p. 285), and Dr. T. H. Holland's paper on the occurrence of bauxite in India. The latter author directs further attention to the aluminous nature of the Indian laterites, and throws the whole field of these rocks open to the prospector. He points out (General Report of the Survey, *ibid.*, p. 142) that the red bauxites of Les Baux were first worked as iron-ores; and in his paper on bauxite the analyses of Indian samples are all from rocks previously known as laterites. A very interesting point is the high percentage of titanium dioxide revealed, and Dr. Holland supports Dr. R. S. Bayer in believing that some unfamiliar and possibly new substance becomes precipitated with the titanium in these cases. Dr. Holland regards bauxite as an intimate admixture of gibbsite, $Al_2O_3.3H_2O$, and diaspore, $Al_2O_3.H_2O$.

Another Indian paper is by Mr. E. W. Wetherell, on the dyke rocks of Mysore (*Mysore Geological Department Memoirs*, vol. ii.), in which a large number of specimens are conscientiously described. The descriptions suffer, however, from the fact that the species of triclinic felspar are not determined. Nor are the misprints so few as the "corrigenda" might lead one to suppose. The drawings for the plates show exceptional care and delicacy.

Mr. G. H. Girty, of the U.S. Geological Survey (*Proc. Washington Acad. of Sciences*, vol. vii., June 20, 1905, p. 1), has instituted a comparison between the Carboniferous faunas of western America and those of Russia and other areas. The ultimate result tends to the increase of the Upper Carboniferous series in America at the expense of beds now classified as Permian. The polyzoan Archimedes, moreover, is shown to possess a far wider range than would be gathered from a consideration of the typical American deposits.

Messrs. Stanton and Hatcher, assisted by Mr. Knowlton, discuss the geology and palæontology of the Judith River beds, in northern and central Montana and the adjacent parts of Canada (Bulletin 257, U.S. Geol. Survey, 1905). The outcome of stratigraphical study, and the examination of the vertebrate and plant remains, show that these beds are no longer to be regarded as on the Laramie horizon, but are Senonian at the highest, and reach down to the Cenomanian.

The same survey (Bulletin 262) issues contributions to mineralogy, by several authors. The researches on which these careful papers are based arose in connection with the general work of the survey, and the results are here conveniently brought together. Messrs. Hillebrand and Ransome discuss the nature of carnotite (p. 18), which, "instead of being the pure uranyl-potassium vanadate, is to a large extent made up of barium and calcium compounds." From this "mixture of minerals" the true carnotite remains to be extracted and defined. Messrs. Lindgren and Hillebrand (p. 48) incidentally direct attention to the optical properties of chrysocolla, which, though noticed by Jannetaz, have been very generally overlooked. Mr. Schaller (p. 115) gives us a critical analysis of dumortierite, deducing thence the formula

$$8Al_2O_3.B_2O_3.H_2O.6SiO_2.$$

The boron oxide was first indicated by R. B. Riggs in 1887. These are only a few of the matters that will attract mineralogists to these 147 pages.

The surface-features of the glaciated areas of North America have provided a wide field for description and for controversy. Mr. R. S. Tarr has sent us four papers, in which various problems are set forth. That on moraines of the Seneca and Cayuga lake valleys (*Bull. Geol. Soc. America*, vol. xvi., p. 215) is mainly descriptive. The drainage-features of central New York (*ibid.*, p. 229) involve questions of stream-capture, the lowering of water-partings, and the formation of new slopes by detrital deposits, such as delight the glacial expert. A geographical account of the gorges and waterfalls of central New York (*Bull. American Geographical Soc.*, April, 1905) is largely concerned with the relations of pre-Glacial and post-Glacial

valleys. Of still more general interest is the paper on some instances of moderate glacial erosion (*Journal of Geology*, vol. xiii., 1905, p. 160), with its examples of granite boulders lying in a sand derived from their own decay, and left undisturbed by the passage of an ice-sheet over them. The remarkable variations in the intensity of glacial erosion recorded by Dr. Ampferer from the valley of the Inn (NATURE, vol. lxxi., p. 236) might be cited in support of the author's observations.

The sixth volume of *Spelunca* is to be devoted to a review and bibliography, by M. E. A. Martel, of all papers on caves published so far in the twentieth century. The first part, issued in June, 1905, covers the papers dealing with France, and the enthusiastic author has spared no pains in making a series of complete and valuable abstracts. The result is a readable work, full of attraction for the geographer as well as the geologist, in which M. Martel devotes most of his own energies to the tracing out of the courses of underground streams.

In the *Geological Magazine* for 1905, Dr. Francis Baron Nopcsa has begun a study of the remains of British dinosaurs, preserved in the collections of the British Museum at South Kensington. He shows that some crocodilian remains are mingled in the rock with those of Polacanthus. The remarkable bony dermal armour and the general skeleton of this dinosaur are figured, and the inflexible union of the lumbar vertebræ is pointed out as a unique feature in this group. The author is, indeed, led to style Polacanthus a sort of glyptodon among dinosaurs.

G. A. J. C.

THE FORTHCOMING INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

THE sixth International Congress of Applied Chemistry, already mentioned in NATURE (this vol., pp. 322 and 421), will be opened at Rome on April 26 by H.M. the King of Italy. The work of the congress is divided into eleven sections, and in each section an extensive programme has already been organised. Many of the most eminent chemists of Europe and America have promised to attend and deliver papers. Sir Wm. Ramsay will give an address on the purification of sewage, Prof. Moissan will lecture on the distillation of metals, and Dr. A. Frank, of Berlin, on the direct utilisation of atmospheric nitrogen in the manufacture of manures and chemical products. Among the numerous papers which have been received by the committee of the congress, the following may be noticed as possessing general scientific interest:—

Section ii.—The extraction of thorium and cerium from the monazite sands, and their utilisation in Welsbach mantles, by Prof. F. Garelli and G. A. Barbieri.

Section iii. (metallurgy).—The actual state and the future of thermoelectric metallurgy, especially with regard to steel, by Major E. Stassano; report on the state of metallurgy in France, by the Comité des Forges de France.

Section vii. (agricultural chemistry).—Chemical changes during the assimilation of nitrogen by bacteria, by Dr. J. Stoklasa; the significance of the bacterial examination of soils, by Prof. Remy.

Section viii. (hygiene and medical chemistry).—The value of inulin as food in glycosuria, by Prof. C. Ulpiani; our present knowledge of the fats from the standpoint of physiological chemistry, by Dr. A. Jolles; inosuria, by Dr. Meillère.

Section x. (electrochemistry and physical chemistry).—This section is represented by more papers than any of the other sections. The following may be mentioned:—Certain cases of hydrolysis, by Prof. Veley; the van 't Hoff-Raoult formula, by Prof. W. D. Bancroft; isomorphism and solid solutions, by Prof. Bruni; electrochemistry of non-aqueous solutions, by Prof. Carrara; relations between proteids and electrolytes, by Prof. Galeotti; action of catalysts in the Deacon process for manufacturing chlorine, by Prof. G. M. Levi; silicide of carbon and the calcium carbide industry in France, by Prof. Moissan; catalysis by common metals, by Prof. Sabatier; chemistry of colloids, by Prof. Beckhold; amphoteric elements, by Prof. Le Blanc; toxins and anti-toxins, by Prof. Ehrlich; solid polyiodides of the alkali metals, by Prof. Abegg; dissociation of fused salts, fused silicates, and glasses, by Prof. Doelter.

The Italian State railways have granted to the members of the congress and their ladies a reduction of about 60 per cent. on the price of an ordinary railway ticket from the frontier to Rome. On their arrival in Rome members of the congress will receive from the committee a book of coupons, which will enable them to obtain at any station tickets at fares reduced by 40 per cent. to 60 per cent., according to the length of the journey. These tickets are available from April 26 until June 11, so that members of the congress may have the opportunity of visiting the International Exhibition at Milan. The subscription fee for membership of the congress is 20 lire for gentlemen and 15 lire for ladies. A special ladies' committee has been formed to receive foreign ladies with the purpose of making their stay in Rome as pleasant as possible.

All inquiries should be addressed to the bureau of the congress, 89 Via Panisperna, Rome

PHYSICAL CONDITION OF CHILDREN IN ELEMENTARY SCHOOLS.[1]

THE physical condition of those who are about to enter on active service in the affairs of life, and whose energy is the chief of the national assets, is certainly a matter of great national importance. Every effort is justified in producing as effective a working community as is possible, and Dr. Kerr's report affords welcome evidence of the increasing concern with which those who direct education are regarding the physical conditions of child-life.

During the period dealt with in this report a limited investigation was made of the conditions of some 3500 of the girls and boys attending the Council's schools, and very striking were the results obtained. It was found that some 42 per cent. of these possessed insufficient clothing to retain animal heat, and therefore stood in urgent need of help in this direction; it is not surprising to find that these children were below the average weight of the school for their age; 45 per cent. of those examined had dirty clothes and bodies, and about one-quarter of these were in a verminous condition; here again these children fell distinctly short of the average age weight. The above results tend to show, perhaps, no more than the fact of poverty, although the excessive shortage of weight in the worst clad class of scholars suggests that insufficiency of clothing is a definite factor in producing malnutrition, the insufficient food energy being first taxed to keep up the animal heat.

The greatest effect upon the life capital of the population is produced by the infantile mortality, which in some years actually kills off during the first year one in five of all children born; the question naturally arises, what is its effect upon the survivors? Does the adverse environment which slaughters one in five have a maiming effect upon those left? Dr. Kerr's investigations indicate that the children born in a year when infantile mortality is low show an increased physique, and those born in the years of high infantile mortality show a decreased physique. It appears, therefore, that in the years of high infantile mortality the conditions to which one in five or six of the children born are sacrificed have a maiming effect upon the other four or five.

The examination of the teeth of some 1500 school children demonstrated that, in the case of the boys, some 90 per cent. had caries, and 70 per cent. to a serious extent. Only the boys who had insufficient grinding surface were below the average in physique. It appears, therefore, that caries must be severe to produce an effect on nutrition.

As the result of an examination of the condition of the eyes, it was found that a constant number of about 10 per cent. of scholars have bad vision; and it is estimated that deafness alone is probably sufficient to interfere

[1] "Report of the Education Committee of the London County Council submitting the Report of the Medical Officer (Education) for the Year ended March 31, 1905." No. 922. (London: P. S. King and Son, 1905.) Price 1*s*., post free, 1*s*. 2*d*.

to a considerable extent with the educational instruction of at least 5 per cent. of scholars.

The necessity for increased endeavours to obtain better physique is sufficiently obvious to anyone visiting the schools, and it is satisfactory to find that the school exercises are being improved.

Dr. Kerr deals in this report with the question of the exclusion of children from school attendance between the ages of three and five years. He appears to favour the existence of the present state of things, but in this view he will probably not receive much support from medical officers of health. Doubtless school attendance affords facilities for the spread of certain communicable diseases (70 per cent. of the infants under five who are at present admitted to the Council's schools have not yet had measles or whooping-cough), and the advantage to the child of postponing attacks from these diseases for even a year or two is so great that it offers one strong argument in favour of excluding children under five from school attendance. Dr. Kerr states that children learn more in the years three to five than they will learn in the same period at any time subsequently. But in children between three and five the reasoning from what they see and hear is very slight indeed, and in the opinion of many the child does not really stand in need of school-teaching before it reaches the age of five.

Increasing solicitude is shown in regard to the personal cleanliness of the children attending the public elementary schools, and Dr. Kerr discusses some of the problems underlying the difficult question of dealing with underfed children. The nurses working under the Council are accomplishing a highly important work of considerable educational value in examining for cases of ring-worm, vermin, and unwholesomeness, and in many cases they follow up their school work by home visits. In connection with the campaign now being carried on in favour of personal cleanliness in schools, the provision of school washing-baths, as distinct from swimming arrangements, is becoming increasingly necessary in many parts of London.

The more important facts dealing with infectious disease in this report relate to the subjects of diphtheria and measles. From the result of much observation and many carefully recorded facts, Dr. Kerr concludes that when a school becomes a source of infection it is generally found that the cases of diphtheria are connected with a class or classes in which the average age of the children is between five and eight. Rarely do cases below five or above eight become sources of infection, and never has it happened in the investigations that a class the average age of which is less than four or above ten has been found to be acting as a disseminating centre. These classes appear to become sources of infection because the children at these ages have the power of partial resistance to the onslaught of diphtheria bacilli, and a large proportion of them are capable of attending school while suffering from slight attacks. Dr. Thomas, the assistant medical officer, in a valuable report upon measles and school closure, concludes that in London at present the disease only spreads in classes under five years of age, except in certain better-class districts, and that to effect any useful purpose school closure must take place before the "first crop" falls. The old practice of waiting until the attendance fell to a certain limit was useless in arresting the spread of measles, and did absolutely no good.

STUDIES OF NATIVE TRIBES.

The American ethnological work in the Philippines is making steady progress. The first part of vol. iv. of the publications has just appeared. It deals with Moro history, law, and religion. Mindanao and Sulu were conquered in the Middle Ages by Mohammedans, who established a new form of government and introduced a written code of laws. Previous to this there was no written history, but thenceforth the datus or chiefs kept their genealogies, and these, brief though they be, are the only sources for Moro history. Prior to the American acquisition of the islands the *tarsila* or genealogies were rigidly kept out of sight of all foreigners and non-Mohammedans, but the Ethnological Survey has been successful in getting copies of many of them; these have now been translated, and are published in the volume before us. The Moros comprise various tribes, which differ as considerably as the Ilocano and the Igorot; the language is Malayan, but the characters employed are Arabic, which makes the work of transliteration no easy one. Some pages of the codes are published here in facsimile; the genealogies are reproduced in the ordinary form, and an exact translation of the genealogy and commentary is also given. There are introductory sections, but perhaps it would have been well to add explanatory notes to the translations in addition.

In vol. xxxix. of the Proceedings of the Royal Society of New South Wales, and also in the Journal of the Geographical Society of Queensland for 1905, Mr. R. H. Mathews maintains (1) that Australian tribes do not practise exogamy; (2) that the eight clan tribes trace descent through the mother; and (3) that there is a cross-division, cutting through phratries and classes, in the eastern tribes. His first and second points are based on the alleged possibility of marriage with any woman of the same generation. His third point, confirmed by Dr. Howitt ("Native Tribes," p. 106 n.) in some measure, may be correct, but seems to point rather to totemic exogamy within the phratry. Mr. Mathews would do well to give (1) the names of all correspondents, and (2) actual genealogies, so that his statements can be verified. He should also explain the object of phratries and classes, if they are not regulative by marriage; success in this would greatly strengthen his case. His researches, if correct, are subversive of much that has been written of late years, but he cannot expect the anthropological world to accept his unsupported statements. If anthropology were officially recognised by the British Empire, evidence on the point would soon be forthcoming. As it is, only untrained observers are available, and much reliance cannot be placed on them.

POLONIUM AND RADIO-TELLURIUM.

Since the discovery of polonium—the first radio-active substance investigated by Madame Curie—much doubt has existed as to its true nature and as to its relationship with radio-tellurium, subsequently separated by Prof. Marckwald from radio-active bismuth salts. Several papers which have recently been published throw considerable light on the problem, without, however, giving to it a definite solution. Madame Curie (*Physikalische Zeitschrift*, No. 5) has determined the constant of decay characterising her "polonium," and finds that it is practically identical with that ascribed by Prof. Marckwald to his radio-tellurium; in both cases the activity falls to half its value in about 140 days, so that there can be little doubt that the two substances are identical. In discussing the chemical properties of "polonium," Madame Curie concludes that there is no ground for considering that it more closely resembles tellurium than bismuth. In No. 4 of the *Berichte* of the German Chemical Society, Prof. F. Giesel has investigated the radio-activity of a "β-polonium" which differs from the older polonium or radio-tellurium by its emitting β rays instead of α rays; the activity of this substance falls to half its value in 6·14 days. This value does not correspond with the rate of decay of any of the known degradation products of radium. Meyer and von Schweidler, on the other hand (Proceedings of the Vienna Academy of Sciences, February 1), have obtained a radio-active bismuth which appears to behave as a mixture of radium D, radium E, and radium F; but Madame Curie (*Physikalische Zeitschrift*, No. 6), in discussing this result, considers that polonium cannot be identical with radium D or radium E, but only with radium F. Closely connected with these researches must be mentioned an investigation by Prof. H. Becquerel (*Physikalische Zeitschrift*, No. 6) of some of the characters of the α rays emitted by radium, and by substances rendered active by radium.

MEDITERRANEAN FEVER.[1]

THE reports of the commission for the investigation of Mediterranean fever, part iv., recently issued, contains a number of important papers. It is shown that in 80 per cent. of patients the *Micrococcus melitensis* is present in the peripheral blood, but usually not in large numbers (Staff-Surgeon Gilmour, R.N.), that it can be recovered from most of the organs and tissues *post mortem*, and from the urine, but not from the saliva (Captain Kennedy, R.A.M.C.). A critical examination of the blood for the agglutination reaction, by Fleet-Surgeon Bassett-Smith, R.N., shows that the blood in 148 cases, other than Mediterranean fever, gave an agglutination reaction only in four. The four latter had recently returned from Malta, and, though suffering from other affections at the time, had had the fever. The agglutination test is therefore perfectly trustworthy. Three papers deal with the possible propagation of the disease by insects. Mosquitoes, *Culex pipiens* and *Stegomyia fasciata*, were proved to be capable of carrying infection; in one case it was highly probable that a human being had been infected in this way, and experimentally one monkey was thus infected (Major Horrocks and Captain Kennedy). In view of the observations recorded in a previous report of the natural infection of goats with the *M. melitensis*, the further investigations in this direction are of great interest. Major Horrocks and Captain Kennedy find that 41 per cent. of the goats in Malta are infected, and that 10 per cent. supplying milk excrete the *M. melitensis* in their milk, and monkeys and goats can be infected by feeding with the infected milk. Cows, bullocks, mules, and in one instance a dog, are other animals proved occasionally to be infected. Like goats, cows may transmit the micrococcus in their milk (Staff-Surgeon Shaw, R.N., and Captain Kennedy). These results suggest that a very important source of human infection is from domestic animals, particularly *viâ* milk. Ambulatory cases in man and the excretion of the micrococcus in the urine are also sources by which infection may be transmitted both to man and animals.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

At the University of Messina, Profs. G. Bagnera and E. Bortolotti have been appointed to chairs for higher analysis and calculus respectively.

At the annual graduation ceremonial of the University of St. Andrews, on Tuesday, the honorary degree of LL.D. was conferred upon Dr. A. C. L. G. Günther, F.R.S., Prof. J. Cook Wilson, professor of logic in the University of Oxford, and Prof. A. H. Young, professor of anatomy in Victoria University, Manchester.

At Lehigh University a course in electrometallurgy has been established. In its main outline it is similar to the course in metallurgy, but differs from it in omitting assaying and geology. The time thus gained is devoted to electrical engineering. There are thus two courses of four years each offered in the department of metallurgy.

Some interesting data relating to the heating of university buildings are contained in a paper by Mr. H. W. Spangler in the Journal of the Franklin Institute of Philadelphia (vol. clxi., No. 3), in which he describes the system of heating and lighting the dormitories of the University of Pennsylvania from a central station about 1200 feet away.

In addition to the Clift-Courtauld and Pfeiffer scholarships to be awarded in June, the council of Bedford College for Women offers a Deccan scholarship in science, value 60*l.*, for three years, on the result of the entrance scholarships examination. The scholarship will be awarded only to candidates who wish to qualify themselves to earn a living, and cannot obtain their university education without pecuniary help.

A private view of the exhibition of students' work will be held at the Borough Polytechnic Institute on April 7. In view of the attention which is being directed to the work done on the Continent and in America in the direction of industrial training for apprentices, many men of science interested in educational problems may be glad to learn more of the work of an institute which has made industrial training, combined with a good educational foundation, one of its strongest features.

A preliminary meeting in connection with the second International Congress on School Hygiene, to be held in London in August, 1907, was held at the University of London on March 30. Sir Lauder Brunton, F.R.S., president of the congress, announced that French educationists and medical men have determined to do all in their power to make the congress in London a complete success, and other countries have taken the matter up. A gratifying reception has been accorded to the idea of an international congress both in Canada and in South Africa, and it is hoped that at the congress there will be a thoroughly representative gathering, not only of the colonies, but of every civilised country in the world. The congress, Sir Lauder Brunton said, promises to be one of the largest and most important ever held in London. Resolutions were adopted approving the idea of holding the second congress in London, asking the King to extend his Royal patronage to the congress, approving the steps already taken to initiate the arrangements for the congress, and inviting the cooperation of educational and municipal authorities, societies, and other representative bodies interested in education and the health and development of children during school life.

The annual dinner of the Bristol University College Colston Society was held on March 30. The president, Mr. J. W. Arrowsmith, announced the receipt of a cheque for 500*l.* from Lord Strathcona, who was unable to attend. He added that for the past six years an anonymous donor has sent the college 1000*l.* annually for its sustentation fund. The Hon. Mrs. Whittuck, of Bath, has offered 1500*l.* to form part of the endowment of a chair of economic science, provided the council of the college sees its way to establish such a chair. It has been determined to take up in earnest the task of establishing a university for Bristol, and a committee has been formed, covering the counties of Wiltshire, Somerset, and Gloucestershire. Lord Winterstoke has offered 10,000*l.*, Mr. J. S. Fry 10,000*l.*, and Sir Frederick Wills and Mr. F. J. Fry 5000*l.* each, thus making up 30,000*l.* Altogether from 150,000*l.* to 200,000*l.* are wanted. Mr. Whitelaw Reid, the United States Ambassador, and Mr. Birrell, President of the Board of Education, both responded to the toast of "Our Guests." Mr. Reid described American experience in the founding of universities. The people of the United States began by copying Oxford and Cambridge, the only two English universities in 1833; but in time they found that the demands of a new people, and of a continent that had to be subdued to the uses of civilisation, called more and more for some higher education of a different kind. Thus while the great English schools still adhered chiefly to the humanities, theirs began a divergence, which every year found more decided, towards science and its applications. The most notable tendency as yet in recent higher educational development in America is towards scientific and technological study with a specialisation always growing more precise, if not also more narrow, in reference to the student's intended pursuits in life. After describing the development of schools and institutions of higher education since the Civil War, Mr. Reid went on to say that none of these schools has money enough, though many of them have considerable amounts. First, of course, stands the Leland Stanford with its princely endowment, from one man and his wife, of between seven and eight million pounds. Next comes Columbia with more than six million pounds, then Harvard with about five and a half millions, Chicago with nearly four millions, and Cornell with nearly three. The great work of Yale has been done with true Connecticut

[1] "Reports of the Commission appointed by the Admiralty, the War Office, and the Civil Government of Malta for the Investigation of Mediterranean Fever, under the Supervision of an Advisory Committee of the Royal Society." Part iv. Pp. 187. (London: Harrison and Sons, 1906.) Price 3*s.* 6*d.*

thrift, since they cannot yet count up quite two millions of pounds; and that of Johns Hopkins, briefer but also great, has been achieved with an endowment of little above one million. The Carnegie Institute at Washington has two millions. Many of the other institutions of higher learning are far less adequately provided for; but in general it may be said that the Republic is more liberal with its schools than with anything else. In no other field do its private citizens display more generosity, and as for public expenditure, to give but one illustration, it may be mentioned that the single State of New York spent in 1905 from the public treasuries, State and local, for its schools in the neighbourhood of nine million pounds.

SOCIETIES AND ACADEMIES.

London.

Royal Society, December 7, 1905.—"On the Influence of Bias and of Personal Equation in Statistics of Ill-defined Qualities: an Experimental Study." By G. Udny **Yule.** Communicated by Prof. O. Henrici, F.R.S.

To attempt to answer the question raised by the results of the preceding investigation an experiment was conducted, by asking observers to classify under such headings as "light," "medium," "dark," scraps of photographic paper printed to different depths of colour. The results show that (1) personal equation in the use of such terms is very large indeed; (2) the majority of observers tend to return an excess of pairs of tints of the same name; (3) the amount of this excess is increased when different observers' results are pooled, owing to their varying personal equations; (4) but it is markedly less than the excess of the number of homonymous pairs (as compared with a normal distribution) in several of the tables for inheritance of qualities. The answer to the question remains therefore somewhat indefinite, and further investigation is required.

Chemical Society, March 15.—Prof. R. Meldola, F.R.S., president, in the chair.—The interaction of well-dried mixtures of hydrocarbons and oxygen: W. A. **Bone** and G. W. **Andrew.** The results of experiments carried out chiefly with well-dried mixtures of ethylene and oxygen indicate that steam is not essential to the combustion of hydrocarbons.—The explosive combustion of hydrocarbons: W. A. **Bone** and J. **Drugman.** The results of this research indicate that there is no essential difference between the slow and rapid combustion of a hydrocarbon, and that explosive combustion probably involves the initial formation of unstable hydroxylated molecules, which subsequently undergo thermal decomposition into simpler products.—The occurrence of methane among the decomposition products of certain nitrogenous bases as a source of error in the estimation of nitrogen by the absolute method: P. **Haas.** The author confirms and extends to a large number of substances Dunstan and Carr's observation that in the Dumas method of determining nitrogen in organic substances an error may be caused by the inclusion of marsh gas in the gas collected and measured.—Studies on comparative cryoscopy, part iv., the hydrocarbons and their halogen derivatives in phenol solution: P. W. **Robertson.**—The displacement of acid ions, part i.: A. F. **Joseph.** The author describes his investigations on the quantitative action of hydrochloric acid on the nitrates of potassium, sodium, and strontium, and of nitric acid on the corresponding chlorides.—Additive compounds of arylamines with aromatic nitro-derivatives: C. L. **Jackson** and L. **Clarke.** 4:6-Dibromo-1:3-dinitrobenzene dimethylaniline, 4-chloro-1:3:5-tribromo-2:6-dinitrobenzene dimethylaniline and other similar additive products are described.—Influence of substituents in the trinitrobenzene molecule on the formation of additive compounds with arylamines: J. J. **Sudborough** and N. **Picton.** The formation of additive compounds between α- or β-naphthylamine and *s*-trinitrobenzene derivatives is completely inhibited by the introduction of three methyl-, two methoxy-, or three bromo-radicals into the trinitrobenzene molecule.—The relations between absorption spectra and chemical constitution, part iv., the re-activity of the substituted quinones: A. W. **Stewart** and E. C. C. **Baly.** An examination was made of the absorption spectra of various quinones, and conclusions are drawn as to the conditions in which these substances exist.—The constitution and properties of acyl thiocyanates: J. **Hawthorne.**—A mode of formation of aconitic and citrazinic acids and their alkyl derivatives, with remarks on the constitution of aconitic acid: H. **Rogerson** and J. F. **Thorpe.**—Aromatic sulphonium bases: S. **Smiles** and R. **Le Rossignol.** Two methods of preparing aromatic sulphonium bases are described, (1) from a sulphoxide and phenetole with a dehydrating agent, (2) from a sulphinic acid and phenetole with strong sulphuric acid.—A new form of calcium chloride tube for combustion: A. E. **Hill.** This tube is described and illustrated in the current number of the Proceedings of the Chemical Society, 1906, xxii., 87.—The viscosity of liquid mixtures, part iii.: A. E. **Dunstan.**—The action of phenylpropiolyl chloride on the ketonic compounds, part ii.: S. **Ruhemann.**

Paris.

Academy of Sciences, March 26.—M. H. Poincaré in the chair.—The methods used in the search for luminous particles mixed with the gas of the chromosphere and the solar protuberances. Application during the eclipse of 1905: H. **Deslandres.** The lines due to the gases are readily observed, but the continuous spectrum due to the presence of liquid or solid particles is much more difficult to recognise. The author attacked this problem during the last eclipse, making use of coloured screens to remove the gaseous radiations. A preliminary account of the results is given.—Observations on Gennadas: E. L. **Bouvier.** The author draws the following conclusions from his work in this and a preceding paper on the same subject: the Gennadas are clearly bathypelagic, and do not descend to live at great depths; they do not rise to the surface for reproduction, and are derived from Benthesicymus by adaptation to a bathypelagic existence.—Quasi-waves of shock in the midst of a fluid which is a good conductor of heat: P. **Duhem.**—The Oligocene basin of Ebro and the Tertiary history of Spain: Ch. **Depéret** and L. **Vidal.**—The total eclipse of the sun of August 30, 1905; solar protuberances of two colours: J. **Esquirol.**—A magic square: G. **Tarry.**—The theory of characteristics: E. **Goursat.**—Discontinuous ensembles: L. **Zoretti.**—The development of non-integrable functions in trigonometrical series: P. **Fatou.**—Hyperelliptic surfaces defined by intermediate singular functions: Louis **Remy.**—The deformation of the metals of a railway: G. **Cuénot.**—A mode of construction of aëroplanes allowing of an increase, in notable proportions, of their sustaining power: E. **Seux.**—The evaluation of the power of microscopic objectives: L. **Malassez.**—The variations of the absorption bands of a crystal in a magnetic field: Jean **Becquerel.** The spectrum of xenotime, a uniaxial crystal giving fine absorption bands, was obtained with a Rowland grating, and the effect of placing the crystal in a magnetic field examined. The resulting displacement of some of the bands was much greater than would be expected from the magnitude of the ordinary Zeeman effect in metallic vapours.—Gaseous osmosis through a colloidal membrane: Jules **Amar.** A perfectly dry colloidal membrane is impermeable to carbon dioxide; the gas diffuses through only when the membrane is moist, and the amount diffused diminishes progressively as the membrane dries.—A contribution to the study of the intermittent discharge: G. **Millochau.** New researches on bulbs producing X-rays: M. **Nogier.**—The use of the Cooper-Hewitt lamp as a source of monochromatic light: Ch. **Fabry** and H. **Buisson.** This mercury arc lamp, which is now made commercially, gives a light of uniform intrinsic lustre. The yellow and green rays are so fine as to give interference phenomena with a difference of path of 22 cm., that is to say, of an order of about 400,000. The yellow rays give particularly fine results.—The isolation and some atomic characters of dysprosium: G. **Urbain.** The author has isolated 50 grams of an earth the spectral characters and atomic weight of which show such constancy among the different fractions that it is impossible to imagine that it is a mixture. Details of the methods of separation used and the spectrum observed are given.—The commercial preparation of calcium hydride: Georges F. **Jaubert.** The product, as put on the

market, contains about 90 per cent. of calcium hydride, the remainder consisting chiefly of oxide and nitride. One kilogram of this, when acted on by water, gives about a cubic metre of pure hydrogen. The lifting power of this being about 1200 grams, calcium hydride has been already used in aeronautics.—The action of the xanthic leucomaines on copper: N. **Slomnesco.**—A new type of equilibrium reaction: L. J. **Simon.** The equilibrium studied was the reaction between urethane and pyruvic acid.—Practical details in the estimation of cadmium: H. **Baubigny.**—The estimation of the albumenoid material in milk: MM. **Trillat** and **Sauton.** The method is based upon the property of formaldehyde of rendering the milk albumenoids insoluble without affecting their weight. The working method is given, and also control analyses.—The catalytic action exercised by alkaline and alkaline-earth salts in the fixation of atmospheric oxygen by solutions of polyphenols: E. **Fouard.**—The formation and distribution of the terpene compounds in the bitter orange: Eug. **Charabot** and G. **Laloue.**—A parasite of the pearl oyster determining the production of fine pearls at the Gambier Islands: L. G. **Seurat.** The parasite is named *Tylocephalum margaritiferae*, and, owing to its pearl-forming properties, is of considerable economic importance.—The origin of the nerves: N. A. **Barbieri.**—Hæmatogen and the formation of hæmoglobin: L. **Hugounenq** and Albert **Morel.**—Aseptic hyperthermia due to operations: MM. **Charrin** and **Jardry.**—A contribution to the history of the Piedmont geosynclinal: Émile **Argand.**—A contribution to the physical geography of the Atlas chain of Morocco: Louis **Gentil.**

THE PHYSIOLOGICAL EFFECT OF LIFE IN THE ALPS.

Höhenklima und Bergwanderungen in ihrer wirkung auf den Menschen. By N. Zuntz, A. Loewy, F. Müller, and W. Caspari. Pp. xvi+494, and tables. Dedicated to E. Pflüger, in celebration of the jubilee of his doctorate. (Berlin: Bong and Co., 1905.)

ALPINE literature has a special charm; it re-kindles memories of happy hours spent among the mountains, and thrills us with echoes of that intense delight in life which was the prominent characteristic of days in Switzerland. No doubt many things contribute to the pleasure which the Alps give to thousands of men and women, but one obvious and potent factor is the sense of well-being; we feel that, like the elixir of life, mountain air and scenery rejuvenate body and mind.

In the important work just published by Prof. Zuntz, Prof. Loewy, and their comrades, a scientific basis is afforded for this rejuvenating influence. The volume contains an account of an expedition undertaken expressly to carry out physiological investigations at high altitudes. Such expeditions have been frequently made, the most notable being the pioneer one of Paul Bert, the extensive one of Kronecker and his colleagues, and those which Mosso has repeatedly carried out in the Monte Rosa district. The expedition conducted by Prof. Zuntz has no doubt reaped great advantages from the study of the work of its predecessors, and the results achieved are in consequence more convincing, and from the physiological standpoint more valuable.

Since the object of the expedition was the enlargement of physiological science, the essential features of the account are of necessity somewhat technical. But the volume contains many passages which are of general interest, including an extensive historical account of earlier expeditions. There are in every one of the twenty-two chapters passages which will appeal to all those who love the Alps, for Prof. Zuntz is himself one of this fraternal band, and reveals his own enthusiasm not only by the character of the descriptive writing, but more directly by the interpolation of many beautiful Alpine illustrations. Moreover, such practical details as clothing, food, and exercise are dealt with from the alpinist's point of view, and what is termed "sport" is treated in a most suggestive way.

To the majority of readers, especially if they should be medical practitioners, the most interesting portions of this really great work will be those which set forth the peculiarities of the climate in high altitudes and the influence which these peculiarities must exert, not only on vigorous athletes who climb the topmost peaks, but on the ever-increasing number of less ambitious mortals who seek the Alps in order to restore shattered health, or to check the advance of disease. In chapter xx. the benefits and dangers of life in moderately high altitudes are set forth in the light of the results of the expedition; the new basis for estimating the value of such benefit or the extent of such danger which is given in this part of the work should of itself secure the general reputation of the volume owing to its direct bearing upon some of the most important hygienic topics of the day.

It is impossible in the short space of this notice to do justice to such a comprehensive volume, but since the essence of the work lies in the physiological effects which were observed at high altitudes, and these form the basis referred to in the preceding paragraph, a brief summary of the physiological results must be attempted. In order to realise their nature, the plan of the expedition will be first described.

Two physiological professors, two assistant professors, and two younger members of the medical profession engaged in physiological research formed the *personnel* of the expedition. For more than twelve months each member of the party had made elaborate experiments of a preliminary character in the Berlin laboratories in order to become efficient in the quantitative work necessary for the investigation of the body metabolism. The details of the expedition were planned with great care and forethought; valuable aid was afforded by Prof. Kronecker, of Berne, and Prof. Mosso, of Turin, the most essential feature of this help being the offer of the working laboratories established in the Brienz district by Kronecker and in the Monte Rosa district by Mosso. In July, 1901, the actual work was begun at Brienz. This is situated at the east end of the lake of that name, and lies at the height of 1857 feet; it is connected by a mountain railway with the summit of the Brienz Rothhorn (7713 feet). At Brienz each member of the party, by strict diet and other precautions, placed himself in a condition of nitrogenous equilibrium, that is, a condition in which the quantity of nitrogen assimilated from the food is equal to that excreted in twenty-four hours. After a few days the party divided, three members going by train to the summit of the Brienz Rothhorn, the others remaining at the lower level; both groups performed given amounts of muscular exercise and conducted similar physiological investigations. Finally the groups changed places, and the work was continued as before. This formed the first part of the inquiry; the second part was of a more severe character. Starting from that delightful valley in which Gressoney-la-Trinité nestles amongst the flowery slopes of the Lysthal, the party ascended to the Col d'Olen, where, at a height of 9420 feet, Mosso has established his lower mountain laboratory. After spending some days in preparations, four members of the party and Prof. Sella, of Rome, climbed with guides and porters to the summit of the Signal Kuppe or Point Gnifetti of Monte Rosa, 14,965 feet. Here they stayed for seven days in the hut, now widely known as the Capanna Osservatorio Regina Margherita, which was erected for experimental pur-

poses through Mosso's endeavours. The first days were most tempestuous, and the account of the stay on the summit is full of interest; an incident in the week was the recovery of a collapsed Alpine tourist, who, to the surprise of the party, turned out to be a lady. The whole party suffered more or less severely from mountain sickness, and a valuable part of the investigations deals with this familiar complaint.

Animals were taken up all the ascents for experimental purposes, others being left below for control observations.

The physiological results are related respectively to the influence of moderate altitudes, *i.e.* up to 7500 feet, and of high altitudes up to nearly 15,000 feet, the former being chiefly the Brienz-Rothhorn experiments, the latter the Monte Rosa ones. They may be briefly summarised under the following different headings :—

(1) *Blood Changes.*—It is now well known that, as first suggested by Paul Bert, the blood is altered in high altitudes. The most striking change is that discovered by Viault, who found that the red blood corpuscles increased from five millions to seven or eight millions per cubic millimetre of blood. Similar increase was observed in the present expedition, but it was somewhat uncertain in character. The determination of the specific gravity of the blood and of the serum showed that the increase when present was not due to plasma diminution through the excessive evaporation of perspiration; moreover, an examination in animals of the tissue which is the seat of the corpuscular formation (the red marrow of the bones) showed that this was in a state of greatly augmented activity. There is therefore no question that the red corpuscles increase in number, and the authors state in their work that the stimulating influence is the diminished oxygen tension of the blood itself.

(2) *Digestive Efficiency.*—By careful quantitative examinations of the food and excreta, it was shown that altitudes up to 8000 feet exercised a favourable influence upon the completeness of the digestive processes, the indigestible residues diminishing especially when the surroundings were cold. In very hot surroundings this favourable influence was not so apparent, and in these circumstances muscular exertion caused it to be of the reverse type. At very high altitudes, 14,900 feet, the efficiency of digestion was greatly impaired.

(3) *Oxidation Processes.*—The extent of these was determined by the relation between the absorbed oxygen and the total heat production of the body. It appeared that even at such low altitudes as 1500 feet the total oxidation was increased, this being exceptionally high during muscular exertion, whilst in moderate and high altitudes the oxidation processes were greatly increased. The increase is set down to two circumstances; firstly, the diminished thermogenetic capacity of the muscles, which are impaired by the inadequate supply of oxygen in their circulating blood, thus throwing the necessary heat production upon the oxidation of more complex compounds than those offered by the muscles; secondly, the presence in the tissues of abnormal oxidisable substances.

(4) *Proteid Metabolism.*—The most important of the numerous changes brought forward in the results of the expedition are those connected with the fundamental nitrogenous substances, proteids. It has been firmly established in physiology that whilst every growing animal assimilates through food more nitrogen than is excreted, this is not the case in the adult except in special circumstances. Growth implies proteid storage, which is believed to be utilised for the increased formation of cellular structures, and even in the adult such local muscular growth may occur as the result of special muscular exercise, training, &c., but it soon reaches a limit and is comparatively insignificant. In the convalescent it is a marked feature of recovery from wasting illness. After making due allowance for all disturbing influences, a most important result was arrived at by the work of the expedition. Even at Brienz (1500 feet) a stage was reached in which the total N-import exceeded the N-export, whilst on the Rothhorn this excess was most marked. Moreover, this phase of metabolism persisted for a considerable time after leaving the moderately high altitude. This implies the production of a phase of nitrogenous metabolism resembling that of the growing animal; it is, in short, a renewal of youth. It is noteworthy that along with this nitrogen storage there was no corresponding increase of body weight, the intensity of the oxidation processes in non-nitrogenous compounds being more than sufficient to mask the proteid gain. At the highest altitudes the gain was not so apparent, but this is amply accounted for by the digestive derangement which was associated with the mountain sickness.

(5) *Respiration and Circulation.*—The decrease of the oxygen tension in the blood in consequence of the decreased partial pressure of the oxygen of the air was in accordance with the results obtained by Hüfner and others in connection with hæmoglobin. In opposition to Mosso's results the authors found that there was not a decreased tension of carbonic acid in the blood. They bring forward evidence which suggests that deficiency of oxygen in the blood can, like excess of carbonic acid, stimulate the respiratory centre; this is of interest as it is opposed to the physiological view now generally accepted. The peculiar type of breathing known as the Cheyne-Stokes respiration, described by Mosso as occurring at high altitudes, was observed by the members of the expedition on Monte Rosa, but the explanation now advanced is quite different from that offered by Mosso. Zuntz regards the phenomenon as impaired activity of the respiratory centres, which are only capable of being adequately roused if the carbonic acid has by accumulation reached a certain tension in the blood.

As regards the circulatory changes, the only one of a fundamental character appeared to be due to the altered activity of the heart. At moderate altitudes the heart's activity, like that of the respiratory mechanism, is augmented to meet the need for more oxygen and more effective oxygen transport by the blood, but at very high altitudes there appeared to be

a great tendency to cardiac weakness owing to the direct action of insufficient oxygen in the blood supplying the muscular walls of the heart.

This scanty and imperfect sketch may serve to show the very extensive field which is covered by the physiological work of the expedition, but, in addition, many valuable observations were made upon the symptoms, progress, and nature of mountain sickness. The cause of this complaint is, according to the authors, the deficiency of oxygen transport by the blood. The individual variations in the manifestation of the symptoms and the disappearance of the symptoms on habituation are considered to be due to the relative adequacy or inadequacy of the mechanisms by which the organism endeavours to protect itself against this oxygen deficiency. One such mechanism is the circulation flow, and if this is unable to bear the strain of increase, then nervous influences diminish the vascular area of the digestive organs in order to supply, so far as practicable, the higher nerve centres in the brain; in consequence of this anæmia, an extensive derangement of the digestive functions is produced which shows itself in the sickness and other symptoms that are the characteristic features of the trouble.

In conclusion, attention must be directed once again to the practical bearing of the Rothhorn experiments. These deal with the effects produced by moderately high altitudes, and to such altitudes thousands of men and women go every year, whilst the numerous sanatoria frequented by invalids are situated at these elevations. Moderate altitudes of less than 8000 feet appear, in consequence of the lessened atmospheric pressure, to benefit the whole organism in the following particulars. The tissue which produces the oxygen carriers of the blood is stimulated into greater activity, the oxidation of abnormal substances is increased, the heart's action is augmented, the respiratory muscular mechanism is brought into more energetic use, and, finally, that proteid assimilation which is so directly related to cell growth and cell restoration assumes the phase present in the young and growing animal. In consequence of all these changes, and particularly the last one, altitudes of from 4000 to 7000 feet must exercise a most beneficial and even rejuvenating influence. In the case of many invalids the effect will be to arm the body for its fight against such insidious foes as the tubercle bacillus and to hasten recovery in all cases of convalescence from bodily or mental prostration. Only those whose circulation is seriously impaired directly or indirectly by organic disease are debarred from the probability of such beneficial effects.

Experience has revealed to many the profound truth which is expressed in the beautiful and familiar words, "I will lift up mine eyes unto the hills, from whence cometh my help." In their monumental work Prof. Zuntz and his colleagues present physiological reasons for the assurance that whilst mountain scenery may arouse the imagination, mountain air will stimulate those organic functions which form the foundation for health of body and happiness of mind.

F. G.

A COMPREHENSIVE DYNAMICS FOR PHYSICISTS.

The Dynamics of Particles and of Rigid, Elastic, and Fluid Bodies. By Prof. Arthur Gordon Webster. Pp. xii+588. (Leipzig: B. G. Teubner, 1904.) Price 10 marks.

Attention has been directed in more than one recent review to the tendency to over elaboration in the standard treatises to which an English reader would naturally turn for information on such branches of applied mathematics as the principle of least action, the potentials of ellipsoids, or the equations of motion of a perfect fluid. What has been said already must be said again, in order to make good the claims which Prof. Webster puts forward in his preface, and to prove that this book, written by an American and published in Germany, fills a distinct want.

That the student of physics should have to consult five volumes of Routh, three of Love, and a large work of Lamb is a state of affairs which could not very well be allowed to continue. It is true that these treatises afford an excellent preparation for the man who proposes to devote his whole lifetime to mathematical research, regardless of cost. But it is becoming more and more evident that the physicist must know something about the intricate mathematical machinery which has been so successfully employed to bring a large proportion of physical phenomena into one connected theory. We include under this category reversible phenomena. Whether the subject-matter of this book is called dynamics, or the study of quadratic forms, or the theory of geodesics in a hyperspace with special reference to particular definite applications makes no difference. The present reviewer may perhaps be allowed once more to state his conviction that irreversible energy transformations, whether statistical or non-statistical in character, cannot satisfactorily be accounted for as properties of quadratic forms except by the method of energy-accelerations, that is, by studying the *second*, and not the first, differential coefficients with respect to the time of the squares and products occurring in the energy function. But the omission of these phenomena leaves a great portion of modern physics which cannot be properly understood without some knowledge of a very extended and very advanced portion of applied mathematics.

In his preface—which, by the way, is so exhaustive as to leave a reviewer but little fresh to add—Prof. Webster states of the book that "It is obvious that it leads to no particular examinations, from which we in America are to a large extent fortunately free." Examples, as such, are therefore omitted, although most of the standard applications of general principles are included in the text; for instance, motion of a spherical pendulum, the brachistochrone and tautochrone under gravity, potentials of a disc and cylinder, form of a rotating liquid in a uniform field or under self-gravitation, torsion of elliptic and triangular prisms, and so forth. In connection with these applications an intentional feature is very con-

spicuous, namely, the attempt, wherever practical, to illustrate the conclusions by diagrams or by appeal to experiment. Prof. Webster is a firm believer in both the analytical and the geometric method, and he rightly emphasises the importance of Lagrange's monumental work, in which there are no figures, but only algebraic equations. But *in the interpretation of results* the geometrical method is often the most fruitful, and it certainly appeals best to the reader who, like Prof. Webster, regards geometry as a physical subject. Possibly it is not so generally known as it ought to be that one important branch of dynamics, namely, uniplanar rigid dynamics, can be treated practically without the use of analysis by drawing diagrams for each problem, and inserting a force, Ma, at the centre of each mass, and a couple, $Mk^2d^2\theta/dt^2$, about that centre. Be this as it may, the curves illustrating the motions of tops, the compounding of oscillations, and similar problems convey much more meaning than a mere formula.

The book consists of three parts. The first deals with general principles and applications to systems of particles. It contains the principle of least action, the theory of free and forced oscillations for finite systems, and a short account of the theory of cyclic systems. The second deals with statics and dynamics of a rigid body. The third practically treats of continuous distributions of matter the dynamical properties of which are determined by partial differential equations with regard to the space-coordinates. By this we include attractions, theory of the potential, spherical and other harmonic analysis, elasticity, hydrostatics, hydrodynamics and sound.

Like every other book, this one has some good features and some defects. To take one or two small instances chosen at random; it is pointed out, rightly (p. 205), that the statement that forces applied to a rigid body are sliding vectors with five coordinates is not a property of forces, but of rigid bodies. On the other hand, it would be surely better to employ the word translation for rotation-couple on p. 209. Again, on p. 404, the expression for the potential of a distant body is not nearly so convenient as the ordinary form involving $A+B+C-3I$, which is not given.

Prof. Webster assumes a fair knowledge of the calculus, but not of differential equations or of higher analysis. It would, however, appear that a fair knowledge of the geometry of x, y, and z is needed; in evidence of this need, the equation

$$\cos^2\lambda+\cos^2\mu+\cos^2\nu=1$$

appears assumed on the second page. For anyone so equipped, Prof. Webster has "attempted to provide a treatise which would in not over a year's time offer to the student an amount of knowledge of Dynamics sufficient to prepare him for the study of Mathematical Physics in general."

But we are surely justified in examining what chances the English student of physics or engineering has of taking his place beside his American and German rivals in drawing upon this store of knowledge. The hopes that might have been raised a year or two ago as to prospective reforms in mathematical teaching will be sadly dispelled by a study of recent papers set in examinations for leaving school or matriculation. In these we find the old tendency to choke off the learner of an inquiring turn of mind, the old artificial questions on solving meaningless equations and simplifying meaningless expressions, mostly fractional, in short, everything best calculated to encourage mere mental gymnastics and to destroy all power of intelligently assimilating new ideas. The training required to produce a human examination-answering machine capable of working at matriculation level and of going no further would, if directed into a right channel, enable that same learner to differentiate and integrate rational algebraic functions, to calculate the areas of their graphs, and perhaps in the third year of a college course to read this book. G. H. B.

A NATURALIST'S PHILOSOPHY.

Essays on Evolution and Design. By the late Prof. John Young. Edited, with an analysis and an introduction, by William Boyd. Pp. xiii+248. (Glasgow: James Maclehose and Sons; London: Macmillan and Co., Ltd., 1905.) Price 6s.

MANY who knew the late Prof. John Young as a versatile thinker and keen critic will be interested in this posthumous volume which discloses his philosophy. To a wider audience the book will appeal by its vigorous criticism of mechanistic interpretations, its protest against theories of fortuity, and its confession of faith in a cosmic plan. The author seems to have felt acutely that the scientific formulations which attempt to give a genetic description of how things have come about fall very far short of being adequate, and that in any case they are never *explanations* which will satisfy the human spirit. Prof. Young sought to show that whether we consider the fundamental concepts of matter and force, the living organism, or the mind of man, we find that the naturalistic scheme is either guilty of *petitio principii* or of that "materialism" which attempts to give a false simplicity to the facts. The principle of continuity breaks down at every point, and our only alternative to giving up scientific explanation (as so many have done) is to fall back on the idea of design, and to make appeal to "the regulating influence of plan of some sort."

To many it will appear that the bulk of the book is an *argumentum ad ignorantiam*, and that many of the failures in scientific interpretation on which the author laid an incisive finger are only partial and temporary failures. Where he found insuperable difficulties, *e.g.* in the application of the selectionist theory, others find corroboration and encouragement. But it may serve a useful purpose to have vividly pointed out some of the difficulties involved in the origin of living organisms with individualities of their own, in the evolution of many important phenomena of animal structure and function, in the rise and progress of mental life, and in the emergence of the distinctively human "ought." If we under-

stand the author aright, he believed not merely in a "cosmic plan," not merely in a "will behind phenomena," but that "processes are directed by an external power."

Prof. Young seems to have taken the evolution theory *cum grano salis*; he thought that the origin of variations is left unaccounted for, that natural selection is an over-rated factor, that it is a modal, not a causal principle, "subordinated to something other than itself," that the Lamarckian interpretation cannot be disregarded, and that far too little attention is paid by naturalists to the individuality of the organism itself. But apart from his insistence on the necessity of recognising "the regulating influence of plan of some sort," his book is critical rather than constructive. It is matter for regret that he did not live to work out the positive part of his thesis, that "many facts in various fields of inquiry point to the existence of a plan."

The value of the book is increased by an able introduction by the editor, Mr. William Boyd, who also supplies an admirable synopsis of each chapter. It is evident that the essays were not intended by Prof. Young to be given to the public in their present form, for in some parts the argument is neither accurate nor clear. Thus, in regard to Weismann's conception of the germ-plasm, the author wrote:—

"Romanes makes the difficulty more obvious by showing that Weismann's view requires us to believe that the germ plasm is independent of and unaffected by what happens to the parent. It is impossible, therefore, for acquired characters to exist, far less to be transmitted; for no variation, however favourable, can take place unless it was foreshadowed in the ancestral protoplasm. This protoplasm was the component of the first simple forms which came into being. It is immortal. On its characters depend those of its most remote descendants. Now on this view these characters must be represented by particles of some sort, certainly of some magnitude. *What is this but to declare design in its most authoritative form?*"

Still more perplexing is the comparison of the sea-urchin's pedicellariæ with young Crinoids, and the aviculariæ of Polyzoa with Brachiopods.

OUR BOOK SHELF.

Heat and Steam (Elementary). An Introductory Supplement to a Text-book of Marine Engineering for the Use of Naval Officers, &c. By Engineer-Commander Tompkins, R.N. Pp. 54. (Portsmouth: J. Griffin and Co.; London: Simpkin, Marshall and Co., Ltd., 1906.) Price 1s. 6d. net.

The author is instructor in steam and marine engineering at the Royal Naval College, Greenwich, and has prepared a text-book on marine engineering, primarily for the use of naval officers. This text-book has reached a second edition. In connection with recent changes in the training of cadets and junior naval officers, a new syllabus of instruction in heat and steam has been issued by the Admiralty. As a consequence, Commander Tompkins has found it necessary to modify certain portions of his text-book, and has done so in the present pamphlet, which he terms an "Introductory Supplement." Young naval officers will be enabled to use this at once, in association with the text-book, and as soon as arrangements can be made the new matter is to be incorporated in the second edition.

The supplement follows the text-book in clearness and simplicity of treatment, and should be of great value to the classes for whom it has been chiefly prepared. It embraces a brief historical review of the development of steam engines; an excellent summary of the principles of thermodynamics, written in simple language; and a sketch of the applications of those principles to engine design. The work is well up to date; it contains explanations of the types of steam turbines introduced by Parsons and De Laval, and of approved types of water-tube boilers. Measurement of power, the mechanical equivalent of heat the sources and conservation of energy, and estimates of efficiency are dealt with in a manner that makes the subjects intelligible to readers possessing only moderate mathematical knowledge. Some of the illustrations are based on most recent practice, including results obtained by the cruiser *Amethyst* fitted with turbine engines, and the sister ship *Topaze* fitted with reciprocating engines. Commander Tompkins has taken great pains to meet the requirements of the readers for whom the work has been primarily undertaken, and he has succeeded. Outside the officers of the Navy, however, there are many persons who may benefit by his work, especially those who desire to understand the principles of the steam engine and whose mathematical knowledge is limited.

Atlas of Japanese Vegetation. Edited by Dr. M. Miyoshi. Sets i.–iii.; plates 1–24. (Tokyo: Z. P. Maruya and Co., Ltd., 1905.)

These are the first three parts of an atlas depicting various types of Japanese vegetation, and containing twenty-four plates, accompanied by an explanatory text in English and in Japanese. The plates are reproductions from photographs, and it is remarkable, considering the skill and cheapness of artistic labour in Japan, to find that the plates of the third part bear the legend "printed in Germany."

The plates are of varied interest. Those in the first part will prove attractive to owners of gardens in this country. Plate vi. is a view of a garden laid out in Japanese style, and shows a scene entirely different from the so-called Japanese garden which is often seen at great houses in England, and where there is nothing characteristically Japanese in the arrangement of the plants or in the general effect produced by the laying out of the ground. A view of an iris garden is very pretty. Mr. Miyoshi states that the Japanese have evolved nearly 400 varieties of *Iris laevigata* var. *Kaempferi*, which show marvellous diversity in the size, shape, and colour of the flowers, and even in the character of the leaves. *Prunus mume*, also figured, is a Chinese species, so long cultivated in Japan that it is now generally known as the Japanese plum, and of it there are now more than 300 distinct varieties.

The second part consists mainly of forest scenes, the most peculiar of which is one of the Japanese beech (*Fagus Sieboldi*), with a dense undergrowth of *Sasa nipponica*, a small broad-leaved bamboo. The Japanese larch, the Hondo spruce, and some other trees are also figured. The third part is of great interest, showing pictures of plants in the little-known Loochoo Islands, and of these the most curious is a scene representing *Cycas revoluta* dotted over an extensive landscape. There is also a good picture of the screw-pine, *Pandanus odoratissimus*, the leaves of which are now being made into hats by the Japanese in Formosa.

Augustine Henry.

The Integration of Functions of a Single Variable. Cambridge Tracts in Mathematics and Mathematical Physics, No. 2. By G. H. Hardy, M.A. Pp. viii+53. (Cambridge: University Press, 1905.) Price 2s. 6d. net.

Now that function-theory is fairly well developed, it is much easier than it used to be to discuss in an orderly way the elementary problems of explicit integration. By showing how this can be done, Mr. Hardy has produced a very instructive and pleasant supplement to the ordinary text-books. Moreover, he has done a useful service by emphasising the work of Liouville, whose theorem (quoted on p. 49) is of great generality, and occurs with others in memoirs which have not, perhaps, received all the attention they deserve. To these memoirs, as well as those of Abel, Tchebichef, &c., reference is made in the notes and appendix; this, of course, adds greatly to the value of the pamphlet.

It must be remembered that the "Cambridge Tracts," of which this is No. 2, are not intended to be exhaustive, but rather suggestive and helpful to those who are really interested in the progress of mathematical theory, and prepared to study it at first hand. Mr. Hardy seems to have carried out this idea as well as his opportunity admitted; and his reader ought to feel that he gets his half-crown's worth of entertainment. For example, on pp. 13–16 we have Hermite's beautiful way of finding, by elementary *rational* operations, the rational part of the integral of a rational function, and in connection with this an example involving, in an unexpected fashion, the theory of invariants. To the remark on p. 38 it may be added that the problem of deciding whether a given integral is pseudo-elliptic or not is likely to be of a nature quite similar to that of deciding whether two given conics can be associated with poristic circum-inscribed polygons. No finite number of rational operations can give an answer; but we can decide whether poristic polygons of any *assigned* number of sides exist or not. To the references on this subject the names of Halphen and Kowalevsky might have been added.

The Laboratory Book of Dairy Analysis. By H. Droop Richmond, F.I.C. Pp. viii+90. (London: C. Griffin and Co., Ltd., 1905.) Price 2s. 6d. net.

With the progress of technical instruction in dairying a need has arisen for a little handbook on milk composition and simple methods of milk analysis for dairy managers. There is also a need for a short handbook of dairy analysis for the trained chemists who find themselves called upon to undertake analyses of milk, cream, butter, and cheese in the laboratories of agricultural colleges and institutions. Mr. Richmond has attempted to serve both purposes in one little volume, and, as might be expected, the result is not entirely successful. For the chemist the illustrations of laboratory assistants performing simple laboratory operations, such as using a wash-bottle, are, to say the least, unnecessary, while to the dairy manager who is not a chemist the directions for the more difficult analyses would be quite unintelligible.

However, for the chemist the book provides a mass of useful details in a concise form. The analytical methods are well chosen, though it is curious to find no mention of the Westphal balance for the determination of the specific gravity of milk; and we can detect no errors or inaccuracies, though there is occasional need for greater clearness, for example, in the meaning of "the Reichert-Wollny figure." These defects are unimportant, and the book will find a useful place in many an agricultural laboratory.

T. S. D.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Chemistry in Rural Schools.

It has no doubt caused as much surprise to others as it has to myself to read, on the authority of the principal of the South-Eastern Agricultural College, that "chemistry is one of the least suitable of the natural sciences to teach children whose lives will be, or ought to be, spent in the country" (M. J. R. Dunstan, NATURE, March 29, p. 511). I have no doubt that Mr. Dunstan has good reasons to assign for this expression of opinion, but those who are interested in the subject of education in rural schools will probably want some more explicit statement before reconsidering their curricula. For my own part I had come to an opposite conclusion. It has been my privilege during the last few years to have been associated with the founders of two rural schools, one in Essex and the other in Sutherland. The curricula of these schools were very carefully considered by my colleagues and myself, and the question of the suitability of chemistry was never raised; on the contrary, we considered that from the disciplinary as well as from the utilitarian point of view it had everything in its favour. Nor have we had any reason during the existence of these schools to doubt the wisdom of including chemistry in the curricula. As a means of training in experimental method and of inculcating habits of careful observation and accurate reasoning, this science (with physics) has been taught with the greatest success. It is popular with the pupils and of distinct value to them in after life, even when that life is "spent in the country."

Perhaps the best justification I can offer for the conclusion to which my own experience has led me is furnished by the Sutherland Technical School, founded three years ago at Golspie by the Duchess of Sutherland. The pupils in this school are as "rural" a set of lads as could be gathered from any part of the Highlands, being for the most part of the crofter and fishing class. Their age varies from twelve and a half years upwards, and the course of instruction extends over a period of three years. During the first year four hours a week are given to elementary practical physics, and the same amount of time to practical chemistry during the second year. Both physics and chemistry will be continued in the third year. The headmaster, Mr. E. W. Read, writes to me as follows:—"The boys like the work, and find no particular difficulty with it: besides, I find their knowledge a great help in the natural history lessons and in the gardening. Further, I feel strongly that the mental discipline of chemistry properly taught is very great, and is likely to put a boy's mind in the attitude of desiring to keep pace with the progress of the times. Most of our boys will have to go straight to work, and I should be very sorry if a single one left without some knowledge of elementary chemistry."

We have had a similar experience in Essex, and it would be of interest to learn from others who have first-hand knowledge of the teaching of science in rural schools of a similar type to those founded by the Countess of Warwick and the Duchess of Sutherland how far chemistry has been successful as a recognised part of the curriculum. It would appear from Mr. Dunstan's letter that he considers this science to have been inserted in the curricula at the expense of the biological sciences. This is not the case in the two schools with which I am concerned. Natural history subjects (in the broad sense) are also taught, and one of the reasons which weighed with us in including chemistry was that an elementary training in this subject was considered essential as a preliminary foundation for the biological subjects. With respect to the education of young men who are actually "on the land" or who are preparing for rural occupations, the teaching of chemistry at the Central School of the Essex County Council at Chelmsford has always been most successful, both in popularity and in subsequent results. The former staff instructor, Mr. T. S. Dymond, now of the Board of Education, to whose zeal and ability the successful intro-

duction of chemistry among the Essex farmers and horticulturists is largely due, could no doubt furnish some interesting information on this subject. At any rate, it was by the close observation of Mr. Dymond's work during the period of my connection with the Essex Technical Instruction Committee that I was most strongly convinced of the suitability of chemistry as a subject for secondary rural schools.

Mr. Dunstan may, however, not include the work being done at the Chelmsford central school within the range of his criticism, as the pupils there catered for are certainly beyond the age of those attending the other two schools dealt with in this letter. In defending the claims of chemistry as a suitable subject—not dogmatically, for I am quite open to arguments against my view—it is hardly necessary to say that the most liberal interpretation of the definition of the term is asked for, and that my advocacy presupposes that the subject is properly, *i.e.* scientifically, taught. I am quite aware that distinguished authorities like Prof. Clifford Allbutt and Sir William Ramsay have expressed views similar to those of Mr. Dunstan. That makes it all the more necessary, however, to raise the whole question and have it authoritatively handled in the interests of rural education. R. MELDOLA.

April 5.

Carnivorous Habits of the New Zealand Kea Parrot.

IN your issue of December 28, 1905, there occurs a note referring to statements made at a meeting of the Philosophical Institute of Wellington with regard to the habits of *Nestor notabilis*, to the effect that the carnivorous habits that have been attributed to this parrot are exaggerated, if not totally untrue. It is unfortunate that this report of the meeting has obtained the wide currency that NATURE will give it, for it is abundantly evident that the speakers at Wellington were unacquainted with the facts about the kea.

In the course of various trips about the South Island of New Zealand during the last five or six years, I have made inquiries from shepherds and others likely to know about the kea as to how far their own personal acquaintance with this bird tallied with the common statements that they attack sheep. I was surprised to find that, in North Canterbury and in Marlborough, these men doubted the truth of these statements. They had never known the kea attack sheep in these districts. I was, consequently, inclined to take the view just put forward by the members of the Wellington Institute. I then wrote a series of identical letters to run-holders, shepherds, and others who were supposed to have had experience in this matter in Otago, with the result that overwhelming evidence of the existence of this habit was presented to me. Possibly the "naturalists and estate agents" of the Wellington Institute had not tapped the right district; that they gave their opinion in good faith I do not for a moment doubt.

It must be borne in mind that the kea is confined to the high mountainous country of the South (or Middle) Island, and does not occur in the North Island. It lives in the rough mountain tops in Alpine districts, and it is in this high, rough country that the damage to sheep has occurred, as Sir W. Buller has pretty fully described in his monograph on the "Birds of New Zealand."

It was in the Wanaka district, in Otago, that the greatest amount of damage was done in the early days of sheep-farming, and it was to managers of stations, to shepherds, musterers, and "kea shooters" employed on some of these stations that my inquiries were directed.

Several of these run-holders lost sheep by thousands, and reckoned their losses from kea attacks by thousands of pounds; some were practically ruined by the kea and the rabbit combined.

They engaged men specially to shoot and otherwise destroy keas; the county councils gave 1*s.* to 2*s.* 6*d.* a head for the birds; the squatters and Government also paid for beaks. Is it probable that these people would expend hundreds, nay, thousands, of pounds on a chimera?

Let me quote one or two extracts from letters received by me from men who have seen the kea attacking sheep, who have seen the sheep coming in at muster with holes in their sides and the entrails hanging therefrom, and on shearing have noted the wounds on the skin. These men, I may say, are well known in the district, and I have taken every care to apply only to those whose word may be relied on to give their own personal experience. These letters I hope to publish in full in the Transactions of the New Zealand Institute next year, so that their personal experiences in the early days of sheep-farming may be preserved.

Mr. Fraser, now stock inspector in Nelson province, writes:—"I was engaged sheep-farming in the Hawea and Wanaka lake districts in 1871–1883. I lost thousands of sheep from keas. I have seen the kea attacking the sheep, and also eating into a sheep when the latter was stuck in deep snow. I have opened scores of kea crops and found wool and meat therein. I have laid poison in dead sheep in snow, gone back later and found dead keas."

It was at Mr. Henry Campbell's station near Lake Wanaka, Otago, that these injuries to sheep were first (in 1868) traced to the kea, and I quote a letter from a Mr. J. H. King, who, early in the 'seventies, was employed to shoot the keas:—

"I have seen a flock of twenty or thirty birds attack a mob of sheep in the high precipitous country. The sheep as soon as attacked would huddle together as if driven by dogs; the keas would harass them until one kea would suddenly alight on a sheep's back, holding on to the wool of the rump. The sheep so attacked would immediately single itself from the mob and rush frantically about, and would either go over a bluff or drop down from exhaustion, when the kea which had still held on was joined by several others, and they soon destroyed the sheep."

Mr. King has shot a kea which was on a sheep's back.

It may be noted that the attacks are mostly made at night, hence the rarity of personal observation of these attacks; that they occur in a comparatively limited area, from the region of Mount Cook and the Mackenzie country in South Canterbury to the Takitimu range in Southland, but the centre of the area is round lakes Wanaka, Hawea, and Wakatipu.

Finally, as a comment on the irresponsible statements made at the Wellington Institute, I may quote from the *Otago Daily Times* of February 16, 1906:—"A meeting of landholders at Culverden to-day passed a resolution urging the Government to increase the bonus of 6*d.* each paid for keas' heads, and asking the county councils of Canterbury affected by the kea nuisance to cooperate with them in petitioning the Government for assistance in reducing the pest. The keas have been very numerous in the mountainous parts of Amuri county during the last two years. They seem to have moved northwards from Otago. . . ."

The report then proceeds to give the experiences of various Canterbury run-holders, which are in all respects similar to those recorded thirty years ago by the Otago men (*vide* Buller's "Birds" and Hutton's "Animals of New Zealand").

There can be no doubt that the keas have wrought, and are still causing, great havoc among sheep in certain districts.

It may be worth noting that the statement frequently made (*vide* Wallace's "Darwinism") that they "go for the kidney-fat" especially is an exaggeration. Those men whom I have interviewed tell me that the kea will eat any part, even the entire carcase, of a sheep, leaving the bones clean; they are not such "gourmets" as has been supposed. W. B. BENHAM.

Dunedin, February 18.

A New Product of Actinium.

RECENT work has directed attention to the great similarity in the modes of transformation of actinium and thorium. Thorium, probably itself inactive, gives rise to radio-thorium (Hahn, *Jahrbuch d. Radioact. u. Elektron.*, ii., 3330) which emits α rays; radio-thorium forms thorium X, which is followed by the other well known products, the emanation and the active deposit. Actinium behaves in a very similar way. By the same method, which was successful in separating thorium X from thorium, Godlewski (*Phil. Mag.*, July, 1905) showed that a new

product, actinium X, could be separated from actinium. Actinium X produces the emanation, and this in turn the active deposit. The similarity between these two substances is even closer, for I have found that a new product is present in actinium which is intermediate between actinium and actinium X, and, from analogy to thorium, will be called for convenience "radio-actinium." This product emits α rays, is half-transformed in about twenty days, and is the parent of actinium X.

The separation of radio-actinium from an actinium solution in radio-active equilibrium can be often accomplished by producing a very small precipitate in the solution, which settles down slowly and carries with it the new product, while most of the actinium and actinium X remain in the solution. Amorphous sulphur was found to be very convenient for that purpose. To a fairly strong hydrochloric acid solution of actinium some sodium thiosulphate was added, and the small amount of sulphur was allowed to settle down in the cold. After filtration the precipitate was tested for activity. It showed a strong α-ray activity, but comparatively very little β-ray activity, and gave out very little emanation.

The α-ray activity steadily rises to a maximum after about three weeks, the activity then being about two or three times its initial value. The activity then decays and ultimately according to an exponential law, with a period of about twenty days. The β-ray activity and emanating power reach a maximum at the same time, and decay with the same period. This rise of activity to a maximum is due to the formation of actinium X from the radio-actinium. This is shown by the increase of the emanating power, and was also verified by direct separation of actinium X from the radio-actinium. For instance, if one separates the actinium X when the activity of the radio-actinium is decreasing, the activity of the residue again rises and varies in the same way as in the above described experiment. Actinium itself, freed from all its products, gives out practically no α or β rays, but then slowly increases in activity, reaching a maximum after about four months. Godlewski obtained almost inactive actinium, showing that he had unknowingly separated the new product from the actinium. I have observed that when dissolving actinium in hydrochloric acid, generally a small portion remains undissolved, and this fraction contains radio-actinium to a large extent.

Giesel long ago stated that his preparations of emanium increased in activity for about six months. This may probably be explained by the formation of radio-actinium. In a recent paper, Marckwald (*Ber. d. d. chem. G.*, 1905, 2264) compared the chemical properties of actinium and emanium, and concluded that actinium and emanium were not identical, but the latter was the parent of the former, the activity of his actinium decaying in the course of several months. This is in contradiction with Debierne's statement that his actinium does not lose its activity. The decaying substance, separated by Marckwald, which he concluded to be the actinium of Debierne, may possibly be the product radio-actinium, because a precipitation of thorium with sodium thiosulphate carries down the radio-actinium also. But it remains to be explained why his actinium did not rise at first, or why it did not seem to contain actinium X.

It may be mentioned that the above described experiments were carried out both with the actinium of Debierne and the emanium of Giesel. The same results were obtained in both cases.

A more complete account of these experiments will be given later. O. HAHN.

McGill University, Montreal, March 27.

The April Meteors.

THESE meteors will return this year at a favourable period, the moon being near new and only visible as a slender crescent for a short time before sunrise. If the atmosphere should prove clear during the night following Saturday, April 21, a number of Lyrids will probably be seen. The shower is likely to reach its best after midnight, when the radiant at $271^\circ+33^\circ$ will have attained a sufficiently high altitude to favour the visible distribution of its meteors.

The display is seldom very rich, and has not developed striking brilliancy since 1803, but it sometimes offers fairly conspicuous features, as in 1901. Usually it does not equal the strength of the annual Perseid shower of August, and it is certainly of much shorter duration, for its period of special activity is often confined to a few hours. In 1901 the Lyrids were pretty bright and plentiful on April 21, though on the previous night the display could be scarcely recognised during a long watch. An interesting feature of this system is that its radiant, like that of the August meteors, exhibits a daily motion eastwards amongst the stars. This displacement is, however, very difficult to trace owing to the brief duration of the shower, and to its comparative feebleness at many of its returns.

Observers would do well to watch attentively for early Lyrids on April 18 and 19, and for late members of the stream on April 22, 23, and 24 next. Individual meteors, accurately recorded on these dates, may be regarded as very valuable, since it will be possible to compare their paths with duplicate observations secured elsewhere, and thus their radiant points and heights in the air may be determined with trustworthy precision.

Meteors from streams contemporary with the Lyrids are usually somewhat rare, but in recent years two showers of slow-moving meteors have been well pronounced from southern positions at $189^\circ-31^\circ$ and $218^\circ-31^\circ$.

W. F. DENNING.

THE interesting Lyrid meteor shower passed unobserved last year owing to the generally unsatisfactory state of the weather that prevailed at the time of its expected appearance. In the event of better atmospheric conditions obtaining at the present epoch, the Lyrids are likely to be strongly in evidence, as the circumstances that regulate the intensity of these meteor apparitions will be exceptionally favourable. According to calculations by the writer, the Lyrid shower will fall in 1906 on the night of April 19, and will be visible at least in part from both sides of the Atlantic, though the main bulk of the display will descend over the American continent. The earlier maxima on April 19 fall due about 10h. 30m. and 14h. 30m. G.M.T.; the second and stronger phase of the shower will culminate at 19h. 30m., and will be followed by two other maxima, one of which occurs on April 19 23h. and the other on April 20 2h. The last and final outburst of meteoric activity will, of course, completely elude observations over the American continent. Of the minor showers associated with the period, the most prominent will be visible on the nights of April 23 and 25; on the former there is a well defined maximum at 13h., while on April 25 two or three maxima will take effect between 9h. and 12h. 30m. JOHN R. HENRY.

April 7.

Sea-sickness and Equilibration of the Eyes.

IN connection with the above subject, which Mr. Sang brought under the notice of your readers in your number for March 29, I would like to point out that it has been long known that the eyes may play an important part in sea-sickness. When making some investigations connected with a "New Variety of Ocular Spectrum" (Proc. Roy. Soc. Edin., vol. x.), I found that by acting on the eyes alone a very disagreeable sickness, similar to sea-sickness, could be easily produced. The subject was comfortably seated in a chair with his head in a large cylindrical box. The box was open below, but partly closed on the top by a circular piece of wood by which the box was suspended. The cylindrical sides of the box were made of tracing paper having broad black vertical bands painted on it. When the box was rotated on a vertical axis, the black and white vertical bars passed in succession in front of the observer. The effects on the subjects were various; sometimes they felt as if they were rotating in a direction the opposite of that of the box, but the most certain result was a very disagreeable sickness, which continued for some time after the experiment was made. Personally, I find the best preventive of sea-sickness is to lie down and read anything I may be interested in, holding the book in such a position that it shuts out the view of all other objects. JOHN AITKEN.

Ardenlea, Falkirk, N.B., March 31.

NOTES ON SOME CORNISH CIRCLES.[1]

II.

The Tregeseal Circles (lat. 50° 8′ 25″ N., long. 5° 39′ 25″ W.).

There are two circles situated on Truthwall Common near to Tregeseal and not far from St. Just; the one is nearly to the east of the other, and there are outstanding stones, including four holed stones, and several barrows. The eastern temple has a diameter of 69 feet, and includes, at the present time, nine erect and four prostrate stones; the original structure seems to have contained twenty-eight stones according to Lukis.

Photo. by Lady Lockyer.

Fig. 4.—The Eastern Circle at Tregeseal.

Photo. by Lady Lockyer

Fig. 5.—The Mên-an-tol.

My wife and I visited the region in January, 1906, but previously to our going Mr. Horton Bolitho, accompanied by Mr. Thomas, whose knowledge of the local antiquities is very great, had explored the region and taught us what to observe.

The chief interest appears to lie on the N.E. quadrant, where, in addition to a famous longstone on a hill about a mile away, the nest of holed stones and several of the barrows are located. Carn Kenidjack, a famous landmark, lies to the north.

Of the two circles, I confined my attention almost exclusively to the eastern one, as the other is in a fragmentary condition, though it is still traceable. It is hidden almost entirely from the eastern circle by a modern hedge.

Mr. Horton Bolitho, who accompanied us in January, has again visited the spot, with Mr. Thomas, for the purpose of further exploration, and determining the angular height of the sky-line along the different alignments, which I have plotted from the 6-inch and 25-inch maps. My readers will therefore see that my part of the work has been a small one, and that they are chiefly indebted to those I have named.

No theodolite survey has as yet been made for determining the azimuths and the height of hills. The following approximate azimuths have been determined by myself from the 25-inch map, and the elevations by Mr. Horton Bolitho by means of a miner's dial.

Alignments	Azimuth	Elevation
Apex of Carn	N. 12° 8′ E.	4° 0′
Barrow 800′ distant	N. 20 8 E.	3 50
Two barrows 900′ distant	N. 50 8 E.	1 50
Holed stones	N. 53 20 E.	1 15
Longstone	N. 66 38 E.	2 10
Stone	N. 76 13 E.	

The carn referred to in the above table is Carn Kenidjack, called "the hooting cairn." The rocks on the summit, in which there is a remarkable depression, are still by local superstition supposed to emit evil sounds by night.

[1] Continued from p. 367.

Of the sight-lines studied so far, those to and from the Longstone and the holed stones seem the most important. The Longstone,[1] $1\frac{1}{2}$ miles to the N.E., is a monolith 10 feet high on the western side of a hill; it is visible from the circle though furze has grown round and partly hidden it.

The meanings of the various alignments seem to be as follows:—

	Dec. N. ° ′ ″	Star	Date
Apex of Carn	42 33	Arcturus ...	2330 B.C.
Barrow 800′ distant	40 29	,, ...	1970 ,,
Two barrows 900′ distant	25 20 21	? Solstitial	
Holed stones	23 2 20	? ,,	
Longstone	16 2	May sun	
Stone	9 15	Pleiades ...	1270 B.C.

Regarding the possible solstitial alignments, the declinations obtained may be neglected until the azimuths and angular heights of the hills have been determined with a good theodolite. A change of −10′ in the angular elevation, and hence about that in the resulting declination, would bring the date given by the barrows to about 2000 B.C.

The position of the Longstone is well worthy of attention. Several very fine monuments which mark the surrounding horizon are visible from it in azimuths with which other monuments have made us familiar. They are as follows:—

Alignment	Az.	Hills
Longstone to Mên-an-tol ...	N. 50° 30 E. ...	0 34′
,, 9 Maidens (Boskednan)	N. 54 0 E. ...	1 0
,, W. Lanyon Quoit	N. 67 0 E. ...	0 0
,, Lanyon Quoit	N. 72 45 E. ...	0 0

These values, of which the angular heights of the hills were determined approximately from the contours on the 1-inch Ordnance map, lead us to the following declinations:—

Alignment	Dec.	Star	Date
Longstone to Men-an-tol	24° 7 N. ...	Solstitial sun	
Longstone to 9 Maidens (Boskednan)	22 37 N. ...	Solstitial sun	
Longstone to W. Lanyon Quoit	14 3 N. ...	May sun	
Longstone to Lanyon Quoit	10 30 N. ...	Pleiades ...	1030 B.C.

[1] In Cornwall this is the name generally given to a monolith.

The May-sun alignment, it may be noted, differs from that from the circle. The heights of hills when determined may give us the same solar declination; that now used gives the declination of the sun for April 28 and August 15 in our present calendar.

Regarding the alignment on Lanyon Quoit, it need only be pointed out that the Pleiades date obtained is some 200 years after the date obtained for the analogous alignment from the circle, showing that if these two monuments—the Tregeseal circle and the Longstone—have any relationship, the removal to the high plain, now known as Woon Gumpus and Boswen Commons, was an afterthought improvement.

I next come to the holed stones, not only the nest of them not far from the circle, but the famous Mên-an-tol itself.

I had heard before going to Tregeseal that the four holed stones shown on the Ordnance map had been knocked down and set up again (not necessarily in their old places) two or three times. Mr. Horton Bolitho and Mr. Thomas, however, in their examination were convinced that the largest of them has never been moved. They also express the belief that the others are not more than a foot or so from their original positions, and that this change is only due to their re-erection by Mr. Cornish after they had fallen down. So far I have heard nothing of the direction of the hole in the stone which retains its original position.

Another interesting matter is that the explorers in question were able to trace an ancient stone alignment from the circle to the holed stones.

I have long held that these holed stones were arrangements for determining an alignment. The famous Odin stone at Stenness, long since disappeared, was, if we may trust the very definite statements made about its position, used to observe the Barnstone in one direction and the chief circle in the other.

The azimuths suggest that theodolite measures may show that the Tregeseal stones might have been used in the same way; they, the Longstone and Lanyon quoit, are in nearly the same straight line, the alignment, holed stones to Longstone and Lanyon quoit, being N. 67° E., so that the May sunrise may have been noted in this way.

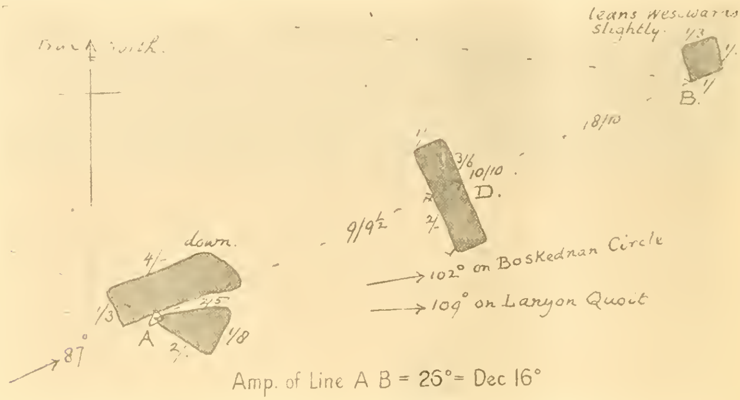

FIG. 6—Plan of the Mên-an-tol from Lukis, showing that it was an apparatus for observing the sunrise in May and August in one direction and the sunset in February and November in the other. Sun's declination. 16 N. or S.

Several other monuments, *e.g.*, Chûn Castle and Cromlech, are to be found in the immediate neighbourhood of the Tregeseal Circle and the Longstone,

but these will have to await further investigation as to their character and antiquity before any conclusions concerning their astronomical use can be deduced.

NORMAN LOCKYER.

IRRIGATION IN THE TRANSVAAL.[1]

THERE are few subjects on which such a great diversity of opinion exists as on the administration of South Africa. Free labour and Chinese labour, the electoral franchise of the Transvaal, the various routes from the interior to the coast, the language to be adopted in Government schools—on these and on many other points one hears well-informed and perfectly honest-minded people asserting, and that with considerable warmth, the most opposite views; views which they maintain are founded on facts.

But there is one subject on which it may be asserted all are agreed, and that is that the great want of South Africa is not gold or diamonds, but water in sufficient volume to be spread over the land when and where it is required. Not that the country is generally devoid of rain, but, as it has been well put, "When rain is wanted it is generally not there; when it is not wanted it is invariably present."

No one was more fully alive to this want than the late distinguished High Commissioner, Lord Milner. He borrowed the services of Sir William Willcocks, one of the most prominent members of the small band of English hydraulic engineers from India who have done so much on the Nile. He further procured two engineers, Messrs. Gordon and Strange, thoroughly trained in the excellent irrigation school of India, to advise, one in the Cape Colony and the other in the Transvaal, upon irrigation matters. Willcocks's tour took place during the war, when he was much hampered by the difficulty of getting about the country. His visit, also, was a short one, but not too short to prevent his submitting a very able report full of thoughtful suggestions. Gordon and Strange went to South Africa after the war. They are there still, and may render invaluable services to the country if the agricultural classes can be made to believe that they have anything to learn, and that there may be advantages in accepting a scheme which requires all to submit to certain restrictions for the benefit of all, instead of each farmer being free to follow his own devices. A distinguished member of the present Cabinet has remarked that the Boer farmer seems to have a perfect instinct for disobeying the law. Unless he learns to substitute for this instinct the dictates of reason, there is little hope of irrigation flourishing in South Africa.

Besides procuring the services of these officers, Lord Milner shortly before leaving South Africa appointed a commission to report on the legislation required to enable the water resources of the Transvaal and Orange River Colony to be thoroughly utilised, and also on "the precautions necessary in dealing with subterranean water, more especially in areas situated on the dolomite formation, so as to prevent as far as possible the diversion of such water from public streams and fountains to the detriment of the public."

It was directed that an interim report should be submitted as soon as possible on this last subject. This report, dated May 20, 1905, is now before us. The commission consisted of Mr. Justice Wessels, Judge of the Supreme Court of the Transvaal, three other Dutch and two English gentlemen, one of whom was Mr. Strange.

The commission has collected a large mass of interesting information and opinions from thirty-one witnesses, of whom no fewer than nine were professional geologists. South Africa is to be congratulated in possessing so many scientific gentlemen whose evidence was of great value. The other witnesses were principally engineers and farmers. Of the latter there were seven.

In framing an irrigation project the two first questions to ask are generally, How much land is it proposed to irrigate? How much water is available to irrigate it? In all but the most favoured countries the area which it is desired to water far exceeds the volume of water available. In the Transvaal the irrigable area can easily be marked out. It is not so easy to say how much water is at our disposal.

Usually irrigation is practised by canals and watercourses drawn from rivers and lakes, natural or artificial. By careful observation one finds how much water, at the season when irrigation is required, can be drawn from the river or lake. Elsewhere irrigation is practised by pumping water from wells, going down to the water-bearing stratum. Such a stratum is usually found in alluvial plains at no very great depth, and wells may be sunk within a few hundred yards of each other without causing injury by one exhausting the other. The recent Indian Irrigation Commission found that in that country about 13 millions of acres were yearly watered in this way.

The peculiarity of the situation on the dolomite formation of the Transvaal is that the subterranean water tapped by the boring rod is not due to the rain which falls vertically on the surface of the land above, but that the whole of the limestone substratum is pierced by holes and tunnels, flowing streams, and stagnant reservoirs, so that if water be pumped from a well there is no certainty that another well situated ten miles off may not be thereby sucked dry.

Ultimately the water finds its way out to the surface through springs discharging at times more than 50 cubic feet per second. It seems evident that the catchment basins of these subterranean waters do not necessarily correspond with those of the earth's surface above, and the problem of defining their limits and

[1] "Inter-Colonial Irrigation Commission." Interim Report. Pp xxxvii + 166. (Pretoria: Government Printing and Stationery Office, 1905.) Price 7s. 6d.

calculating the volume of the water that may be drawn from them is not an easy one. Nor is it rendered more easy by the spirit evinced by the Boer farmer witnesses.

Three of the honoured name of Erasmus (two brothers and the son of one of them) refused to recognise any difference between the ownership of water flowing under his ground and of metals found there. Pressed again and again to see the difference between picking up a diamond found on his lands and pumping away the water drawn in from the lands of others, the reply of one of the farmers was quite clear:—"I consider that it is a bad principle when a man owning land under a properly registered title in any country cannot take full advantage of the profit he is able to make."

Not only did these farmers claim the right to use all the water they could suck into their pumps and employ in irrigating their own lands, but they also insisted on their right to sell to their neighbours the water they did not require themselves.

It might happen, then, that the owner of a small pump large enough for his own fields might find his water supply cut off by a larger pump in his neighbour's farm, and he might have to buy from the owner of this large pump the water that had hitherto been his own.

The situation is evidently a difficult one. If such a case were to occur in India it would probably be ruled that a very careful scientific survey should be made of all the subterranean channels with the view of finding exactly how the waters flow, and that until this point was cleared up farmers should have a restriction put on the area of their lands which they were allowed to irrigate. Probably no one would be wronged if they were each limited to irrigating two-thirds of their farms. But this would require a stronger Government than is ever likely to rule in the Transvaal. Probably the commissioners are right in the recommendations they make, and they know that none more drastic would have a chance of being adopted.

These recommendations, after providing for the wants of towns and of mine owners, are to the effect that farmers should be allowed to pump freely for their own use for watering cattle or for irrigation.

"That traffic in underground water should be prohibited, and that an owner should not be allowed to sell or barter underground water which he does not require for his own use." "That it is unnecessary to prove that water in the dolomite formation flows in channels . . . and that if the Judge thinks that the facts establish a connection between the pumping and the diminution of the water in a stream he can prevent the pumping to such an extent as he thinks fit."

This last recommendation is a most important one. Will the Transvaal judges have the courage to carry it into effect?

Since the above was written, an interesting notice has appeared in Nature of March 1 (p. 426). From this it seems that the subject of underground waters has been occupying attention in the United States. The law there seems to favour the view of the Boer farmer, viz., that the owner of the surface of the land is equally owner of all that lies directly below that surface, whether it be rock, stagnant water or running water. This law is, however, receiving severe shocks from the advance of geological knowledge, and as means have now been found of measuring the flow of subterranean water it is probable that the law may be conformed to what is clearly only justice, and a landowner will not be permitted to take more than his due share of the water that passes under his soil.

THE FORTHCOMING MEETING OF THE BRITISH ASSOCIATION AT YORK.

The fourth meeting of the British Association in York will be held in that city on August 1–8, the date being fixed earlier than usual to enable members and their hosts to combine attendance at the meeting with a subsequent tour abroad or a visit to the northern moors for the shooting season. The association was founded in York in 1831, and had for its first president the Earl Fitzwilliam, F.R.S. It celebrated its jubilee there in 1881, under the presidency of Lord Avebury, then Sir John Lubbock, and it now meets again, after three-quarters of a century, in the city of its birth.

At the inaugural meeting on Wednesday, August 1, Prof. E. Ray Lankester, F.R.S., president-elect, will assume the presidency and deliver an address. On Thursday, August 2, there will be a soirée; on Friday, August 3, a discourse on "Volcanoes" will be delivered by Dr. Tempest Anderson; on Monday, August 6, a discourse on "The Electrical Signs of Life, and their Abolition by Chloroform," will be delivered by Dr. A. D. Waller, F.R.S.; on Tuesday, August 7, there will be a soirée; and on Wednesday, August 8, the concluding meeting will be held.

The sections and their presidents are as follows:—(A) *Mathematical and Physical Science*, Principal E. H. Griffiths, F.R.S.; (B) *Chemistry*, Prof. Wyndham Dunstan, F.R.S.; (C) *Geology*, Mr. G. W. Lamplugh, F.R.S.; (D) *Zoology*, Mr. J. J. Lister, F.R.S.; (E) *Geography*, Sir G. D. Taubman Goldie, K.C.M.G., F.R.S.; (F) *Economic Science and Statistics*, Mr. A. L. Bowley; (G) *Engineering*, Dr. J. A. Ewing, F.R.S.; (H) *Anthropology*, Mr. E. Sidney Hartland; (I) *Physiology*, Prof. Francis Gotch, F.R.S.; (K) *Botany*, Prof. F. W. Oliver, F.R.S.; (L) *Educational Science*, Prof. M. E. Sadler.

To the antiquarian York has preeminent attractions, its Roman remains, its mediæval bars and walls, which still encircle the greater part of the city, its Norman castle and noble minster, being each objects of special interest. The city also contains several manufactories interesting to scientific men; opportunities will be given for visiting these under skilled guidance in the afternoons, after the meetings of the sections. Excursions will be organised to several places of interest.

The neighbourhood of York, though flat, presents many objects of geological and archæological interest, many of which are reached by good level roads; cyclists are therefore recommended to bring their machines with them to the meeting.

It is hoped that it may be possible to arrange for an exhibition of photographs taken by the members in South Africa, for which the reception room affords ample accommodation.

York enjoys exceptional railway facilities, being under four hours from London, five hours from Edinburgh. The various railway companies will issue return tickets, at a single fare and a quarter, from the principal stations in the United Kingdom to York. These tickets, which will be available from July 31 to August 14, may be obtained by members and associates attending the meeting on presentation of a certificate signed by one of the local secretaries. The North-Eastern Railway Company will also issue periodical tickets to members and associates, at cheap rates, for going and returning as often as desired during the time of the meeting between York and the chief places in the district.

An attempt may be made, provided sufficient support is forthcoming, to arrange at the end of the meeting a yachting excursion, lasting two or three weeks, to

Norway or other interesting district, limited to association ticket-holders.

A handbook dealing with the natural history and archæology of the York district has been specially written for the occasion, and a copy will be presented to each member of the association.

It is anticipated that there will be a large amount of private hospitality, and as so many members were unable to visit South Africa last year it is expected that there will be a very large meeting.

THE ERUPTION OF VESUVIUS.

THE activity of Vesuvius, incessant for some time past, has culminated in an eruption which, making every allowance for newspaper exaggeration, stands in the foremost rank of historic eruptions, even if it is not already the greatest of all. It is not yet at an end; we cannot say that it has reached its climax; but the interest excited is so great that some forecast of the future, so far as this is possible, may be attempted.

The late Prof. John Phillips pointed out that the volcanoes of the Phlegræan fields have had two periods of activity, each lasting about four hundred years, and that Etna has also had two great periods of activity, the first of which lasted about 800 years, reaching its maximum in the second century B.C., while the second, commencing about the fourteenth century, had attained its maximum about the end of the eighteenth, after which eruptions declined in violence and frequency; from this he concluded that a period of 700 or 800 years may be assigned to the periods of volcanic activity of Etna. It is probable that in all cases of volcanic activity there is some such period, in which the eruptions, spasmodic at first, increase gradually in frequency until they attain a maximum, and then die out again, the length of the period being determined by the size of the reservoir of molten rock which gives rise to the eruptions; but there is not as yet any means of determining what will be the duration of the present series of Vesuvian eruptions, or whether it has reached its maximum; all that seems certain is that there are no signs of this being passed.

Between A.D. 79, when Pompeii was destroyed, and 1631, eleven great eruptions were recorded; the seventeenth century gave four, the eighteenth twenty-three, and in the nineteenth, up to 1869, the date of Prof. Phillips's work, twenty-four were recorded. After that date there was the great eruption of 1872, and an almost continuous condition of activity ever since. It may be that we have now reached the climax, or the future may have catastrophes in store still greater than that which we are now witnessing; but, if there is any virtue in analogy or inference, centuries must elapse before the mountain resumes that condition of quiescence which existed before our era, and for prolonged periods in the centuries which followed its commencement.

The length of these periods of volcanic activity and the difference between those of neighbouring volcanic centres shows that the cause lies deep in the earth, and that the conditions are beyond our ken. Prophecy must necessarily be vague, and can do no more than indicate the future course of events in the most general and guarded terms; yet mankind will always want to peer into the future. Attempts will be made to predict the time of coming eruptions, and not wholly without justification, for extra-mundane conditions must, to some slight extent, influence the manifestations of volcanic activity. Prof. Palmieri believed that there was a distinct increase in the activity of ejection from the cone and in the abundance of the lava at the new and full moon, and it is possible that a connection exists with cycles of variation of climate, magnetic force, or the frequency and distribution of certain solar phenomena, but the relation may be only of the nature of the proverbial last straw that broke the camel's back. On occasion it may do so, but though sometimes the camel can bear many more straws, at others he has given way before even one was added to his load; and so it is with volcanoes. The cause of their eruptions is so preponderatingly mundane that any slight effect of extra-mundane causes must be elusive, difficult to establish, and only to be detected by the study of a long series of averages. For purposes of prediction they are of little use. There is, however, some comfort for the immediate future in the reported subsidence of Pozzuoli; if real, this probably indicates that the present paroxysm has reached its climax, and will now slowly cease.

From the Press reports of the eruption, the following particulars of scientific interest have been extracted and arranged as a diary of events:—

April 5.—Vesuvius in strong activity. Great blocks of rock hurled as far as the lower station of the funicular railway.

April 6.—The new crater began to emit lava in an abundant stream. The lava has arrived within three or four miles of the village of Bosco-Trecase.

April 7.—Bosco-Trecase destroyed. After midnight loud rumblings were heard, followed by a violent earthquake shock, which shattered the windows in the town. Then lava began flowing from Ciaramella, where a fresh fissure had opened up a few days previously. From the Ciaramella crater masses of incandescent rock were ejected, and a torrent of lava swept down at a terrific speed, flowing in two streams, one 200 yards broad moving towards the centre of the town. The town had hardly been evacuated when the lava invaded the houses, several of which were burned down, and soon Bosco-Trecase seemed to be enveloped in flames. At 6 a.m. Bosco-Trecase was completely surrounded by a stream of lava. The cone on the Pompeii side of Vesuvius collapsed, and on the opposite side a new crater opened at the base of the cone in the Atrio del Cavallo and vomited lava and stones. The principal crater was in violent eruption. Explosions were unceasing. A shower of grey-black ashes fell in the streets of Naples.

April 8.—Central crater of Vesuvius was again emitting quantities of lava. Repeated explosions were followed by subterranean rumblings and by earthquake shocks, which were distinctly felt in the villages at the foot of the mountain. At 12.31 a.m. a slight shock of earthquake was felt at Naples, and a second at 2.10 a.m., both disturbances being accompanied by rumblings. A telegram from Naples at 6.30 p.m. announced that Ottajano, Poggio Marino, and Somma had been entirely abandoned. At Ottajano the lava was flowing 7 feet deep through the streets. At 8 p.m. the flow of lava seemed to be generally somewhat slackening. A shower of black dust, like iron filings, fell throughout Montenegro, covering the surface of the country to a depth of a millimetre with an iron-grey layer. Prof. Mattucci, director of the Vesuvius Observatory, made the following report:—

"The eruption of Vesuvius has assumed extraordinary proportions. Yesterday and last night the activity of the crater was terrific and ever increasing. The neighbourhood of the observatory is completely covered with lava. Incandescent rocks are thrown up by the thousand to the height of 2400 feet, and even 3000 feet, and fall back, forming a large cone. Another stream of lava has appeared from a fissure the position of which is not well defined. The noise of the explosions and of the rocks striking together is deafening. The ground is shaken by strong and continuous seismic movements. The seismic instruments threaten to break, and it will probably be necessary to abandon the observatory, which is very much exposed to electric shocks. The telegraph is interrupted, and it is believed that the funicular railway has been destroyed."

April 9.—The stream of lava in the direction of Torre Annunziata has remained stationary since yesterday evening. The dynamic action of the volcano appears to be

diminished considerably, and the situation now seems to be more satisfactory. The shower of ashes has ceased to pour on Naples. The atmospheric conditions are unfavourable, and the seismic instruments last night registered several earthquake shocks. A steamer with 1000 persons on board left Capri this morning for Naples, but was unable to reach her destination, as when about a mile off the coast the passengers were nearly suffocated by falling cinders and ashes, and the vessel has anchored here so as to enable the passengers to witness the eruption.

Vesuvius Observatory, 6.30 p.m.—Report from Prof. Mattucci:—"The explosive activity of Vesuvius, which was very great yesterday and was accompanied by very powerful electric discharges, diminished yesterday evening. During the night the expulsion of rocks ceased, but the emission of sand increased, completely enveloping me and forming a bed more than ten centimetres deep, which carried desolation into this elevated region. Masses of sand gliding along the earth created complete darkness until 7 o'clock. Several blocks of stone broke windows of the observatory. Last night the earthquake shocks were stronger and more frequent than yesterday, and displaced the seismic apparatus. Yesterday afternoon and this morning torrents of sand fell. While I am telegraphing several balls of fire rise with loud rumbling from the enlarged craters and the new elevated crevasses."

April 10.—Report from Prof. Mattucci:—"Last night was calm except for a few explosions of considerable force from time to time. At 4 o'clock this morning the explosions became more violent. The seismic instruments of the observatory record strong disturbances in the interior of the mountain." The roof of the market of Monte Oliveto, Naples, fell in, on account of the accumulation of volcanic ash upon it.

NOTES.

At a meeting of the council of the Royal College of Surgeons of England held on April 5, the Walker prize of 100*l*., founded by the late Mr. C. C. Walker to encourage investigation into the pathology and therapeutics of cancer, was awarded to Prof. C. O. Jensen, of Copenhagen. The committee appointed to advise the council in reference to the award of the prize was influenced, not merely by the actual work which Prof. Jensen has done in investigating the nature of cancer and the effect of treatment upon it, but also by the extent to which he has opened up a field of research to those engaged in the study of cancer on certain lines, enabling them to carry out their investigations over longer periods of time and under better and more determined conditions than have up to the present time been possible. The Jacksonian prize for 1905 was awarded to Mr. R. C. Elmslie for his essay on "The Pathology and Treatment of Deformities of the Long Bones due to Disease occurring during and after Adolescence." The prize-subject for the year 1907 will be "The Operative Surgery of the Heart and Lungs, including the Pericardium and the Pleura." The subject selected for essays to be submitted in competition for the Cartwright prize for the period 1906–1910 was "Prevention of Dental Caries." The honorary medal of the college was awarded to Lieut.-Colonel Sir Richard Havelock Charles, I.M.S., in appreciative recognition of his gift of anthropological specimens—an addition to the museum of special value and importance, not only on account of the number and variety of the specimens presented, but also because of the authentic particulars attached to them.

At a meeting of the Royal Geographical Society on Monday, Mr. Whitelaw Reid, the United States Ambassador, presented to Captain R. F. Scott, R.N., C.V.O., the gold medal of the American Geographical Society, in recognition of his sledge journey on Antarctic ice and the work of the National Antarctic Expedition.

The secretary to the Post Office has informed the Decimal Association that letters addressed to France and Germany, weighing more than ½ oz. but not more than 15 grams, if only stamped 2½*d*., are not surcharged. Although the difference in weight is but small (about 5 per cent.), still the fact should be generally known, because letters are frequently stamped with 5*d*. which, under this ruling of the Post Office, would go for 2½*d*.

Courses of instruction in oceanic research will be held, as in former years, in Bergen, during the university vacation (August 8 to October 15), mainly on the lines previously adopted. The courses will consist partly of lectures, partly of practical instruction and assistance in laboratory work; excursions will also be made, during which the use of various appliances and instruments will be practically demonstrated. The course will be conducted by Dr. A. Appellöf, Dr. D. Damas, Mr. B. Helland-Hansen, Mr. E. Jørgensen, and Mr. C. F. Kolderup. Anyone desiring to attend the course should make application to the Oceanographical Institute of Bergen Museum, Bergen, Norway, before July 1.

A deputation waited upon Mr. Lloyd-George, M.P., President of the Board of Trade, on Monday to urge the necessity for further amendment of the patent law by legislation which would enforce in the United Kingdom the forfeiture of all British patents for inventions which were worked without, but not within, the United Kingdom, after the lapse of three years from the date of application in the country of origin unless the patentee could justify his inaction to the Board of Trade. In the course of his reply to the views placed before him by members of the deputation, Mr. Lloyd-George pointed out that the Patent Act of 1902 embodied the principle of compulsory working, and he wished to know where the Act had broken down. He thought it necessary to see that, while the commercial community was protected, protection was also afforded to those poor people who, while they have the brains, have not the cash to enjoy the full benefit of their ingenuity.

A committee has been appointed to inquire into and report upon matters connected with the Department of Agriculture and Technical Instruction for Ireland. The committee is constituted as follows:—Sir Kenelm Digby, late Under-Secretary for the Home Department (chairman); the Hon. John Dryden, late Minister of Agriculture in Ontario; Mr. W. L. Micks, member of the Local Government Board for Ireland; Mr. F. G. Ogilvie, principal assistant-secretary for technology in the Board of Education; and Mr. Stephen Brown, chairman of the Kildare County Council. The committee is to inquire whether the provisions of the Agriculture and Technical Instruction (Ireland) Act, 1899, constituting the department, and the methods which the department has followed in carrying out those provisions, have been shown by experience to be well suited to the conditions of Ireland; whether any, and if so what, changes are desirable in those provisions and methods; and to report also upon the relations of the department to the Council of Agriculture, to the Agricultural Board, and to the Board of Technical Instruction; upon its relations to local statutory bodies; upon the funds at its disposal and the modes of employing them, and upon its position in regard to other departments, especially those charged with educational functions.

From the April number of the *Popular Science Monthly* we learn that the regents of the Smithsonian Institution have passed a resolution expressing their profound sorrow

at the death of Dr. S. P. Langley, secretary of the institution from 1887 to his death. The resolution includes the following appreciative record of Dr. Langley's work:—"In the death of Mr. Langley this institution has lost a distinguished, efficient, and faithful executive officer, under whose administration the international influence of the parent institution has been greatly increased, and by whose personal efforts two important branches of work have been added to its care—the National Zoological Park and the Astrophysical Observatory. The scientific world is indebted to Mr. Langley for the invention of important apparatus and instruments of precision, for numerous additions to knowledge, more especially for his epoch-making investigations in solar physics, and for his efforts in placing the important subject of aërial navigation upon a scientific basis. All who sought the truth and cultivated science, letters, and the fine arts, have lost through his death a co-worker and a sympathiser." The executive committee has been requested to arrange for a memorial meeting to be held in Washington; and Dr. A. D. White has been invited to prepare a suitable memorial which shall form a part of the records of the Board of Regents of the institution.

The belemnites of the Speeton Clay form the subject of a paper by Mr. T. Shepherd, issued as No. 29 of Hull Museum Publications.

We have received a copy of a fourth supplement to "A Catalogue of the Books in the Library of the Indian Museum," containing additions from the autumn of 1899 to that of 1903.

In No. 1440 of the Proceedings of the U.S. National Museum, Mr. Knud Andersen describes horseshoe-bats collected in the islands of Nias and Engano, Malay Archipelago. No. 1441 of the same serial is devoted to a revision of American Palæozoic insects, by Mr. Anton Handlirsch, of the Imperial Natural History Museum at Vienna, to whom the Transatlantic specimens have been sent. A large part of the collection was obtained from the Upper Carboniferous shales of Mazon Creek, in Illinois, where they are found imbedded in washed-out nodules. Since only about one nodule in a thousand contains an insect's wing, the search would be impossible were it not for the fact that other fossils are comparatively common. Owing to ill-health, Prof. Scudder was unequal to the task of describing the collections, and it was for this reason that they were handed over to the Austrian palæontologist. The systematic conclusions reached by Mr. Handlirsch differ somewhat from those of Prof. Scudder, and render insect phylogeny simpler. The order of Palæodictyoptera, which is the oldest, is regarded as the ancestral stock from which all other insects are descended. In No. 1439 of the same serial Mr. Handlirsch describes a new and interesting type of cockroach from the Cretaceous beds of the Judith River, Montana.

Parts iv. and v. of vol. xvi. of the Proceedings of the Royal Physical Society of Edinburgh have been received. The former is entirely devoted to a catalogue of the crustaceans of the Forth area, by Dr. T. Scott; while certain rotifers from the same district form the subject of a paper in No. 5, by Mr. J. Murray. The latter issue also contains an important paper by Prof. J. G. Kerr on the embryology of certain primitive fishes, more especially the lung-fishes and fringe-finned ganoids. As the result of his investigations, the author concludes that vertebrate limbs are probably modified external gills, the theory that they are derivatives from a pair of lateral skin-folds being, in his opinion, purely hypothetical, and not supported by embryological evidence. According to Prof. Kerr's view, two pairs of the primitive gills lost their respiratory function and assumed a motor one, developing at first into "stylopterygia," then into the "archipterygia" of Ceratodus, and finally, but independently, into "chiropterygia." This implies the theory that the archipterygium is really the primitive type of fin, and also involves the acceptance of Gegenbaur's idea that limb-girdles represent branchial arches. The limbs of Lepidosiren and Protopterus are regarded as reversions to the stylopterygian type. Further, the author asserts his belief in the intimate relationship between lung-fishes and salamanders. Dollo's theory that the diphycercal tail of modern lung-fishes is derived from a heterocercal type is considered improbable.

We have received copies of the *Sitzungsberichte* of the Royal Bohemian Academy of Sciences for 1904 and 1905. One of the most interesting articles in the former of these is an account, by Dr. G. Eisen, of the now extinct Indians of the Santa Barbara Islands, off the Californian coast. Our knowledge of these Indians is derived from the accounts of the early voyagers, from the missionaries who subsequently settled on the islands, and from the remains in their refuse-heaps and the skulls and skeletons which have from time to time been collected. Some of the islands probably at one time had a population approaching 1000 each, but in 1823 only about 900 were left on Santa Barbara and the neighbouring islets; and by 1875 all had disappeared, the last survivor in San Nicolas having been deported in 1853. Although they manufactured a certain number of domestic utensils, these Santa Barbara Indians are described by the missionaries as the most degraded of all human beings, with a morality lower than that of animals. Insects, especially grasshoppers, formed a portion of their food, and, like the natives of the adjacent mainland, they probably fed to a great extent on the larger kinds of earthworms. Possibly they belonged to the Shoshonean stock of the mainland. Their extermination is attributed to the changed conditions of existence imposed upon them by the missionaries.

In *Science* for March 9 and 16 several papers on yellow fever, read before the American Association for the Advancement of Science, are reported. Prof. Calkins discusses the protozoan life-cycle, and concludes that the yellow-fever microbe probably belongs to the spirochætes. Mr. J. H. White summarises the practical results of discoveries on yellow fever transmission, Mr. H. C. Weeks discusses the practical side of mosquito extermination, and Dr. J. Carrol, in a paper entitled "Without Mosquitoes there can be no Yellow Fever," reviews the evidence, showing that yellow fever is conveyed solely by the mosquito *Stegomyia fasciata*.

In the first number of the *Philippine Journal of Science*, issued in January, Mr. E. B. Copeland, discussing the water relations of the coco-nut palm, attributes much value to an open position where transpiration is considerable and the trees receive full illumination. These observations would help to explain the fact that coco-nut trees growing near the sea shore produce more fruit than those growing further inland, although analyses show very little differences in the composition of the soils.

The second number of the *Philippine Journal of Science* (i., No. 2) maintains the high standard of its predecessor. Mr. H. S. Walker discusses the keeping qualities of coco-

nut oil and the causes of its rancidity; the latter seems to be due to the growth of moulds in imperfectly dried copra. Mr. C. S. Banks describes and illustrates the principal insects attacking the coco-nut palm, and Mr. A. M. Clover writes on Philippine wood oils. Mr. W. D. Smith describes certain Orbitoides from the Binangonan limestone, and Dr. R. Strong experiments on vaccination against plague. Mr. M. Herzog details an investigation on beri-beri, from cases of which he has succeeded in isolating the kakke coccus of *Okata kokubo*.

In the *Bulletin du Jardin impérial botanique* of St. Petersburg (vol. vi., part i.) Mr. A. Elenkin puts forward the view that in lichens the algal and fungal constituents do not exist for mutual benefit, but, being differently acted on by external factors, one flourishes at the expense of the other. Mr. B. Issatchenko, writing on the conditions under which chlorophyll is formed, dissents from the results obtained by Mr. W. Palladin that a concentration of 35 per cent. to 50 per cent. of sugar prevents its formation. Mr. P. Isuzew announces that he has found trees of the bird-cherry with rose-coloured flowers in the province of Perm, and also that early and late flowering varieties were observed growing side by side.

In the *West Indian Bulletin*, vol. vi., No. 4, a number of papers on sugar and sugar cultivation are collected from which a fair idea of the state of the industry in the West Indies can be obtained. While it cannot be said that the industry has been as yet re-established on a sound basis, the opinions expressed by such capable judges as Sir Daniel Morris, Dr. F. Watts, and Dr. H. H. Cousins all point to a successful future if only planters will take advantage of the improved varieties, and if separately or in combination they will arrange for the establishment of factories equipped with modern machinery. New seedlings giving a higher proportion of saccharose are being evolved; the well known seedling B. 208, now under cultivation in Barbados, Jamaica, Queensland, and elsewhere, has been surpassed by another Barbados seedling, B. 1529, and some of the Jamaican seedlings of 1904 promise to give excellent results. The fluctuations of the sugar industry in Antigua and St. Kitts during the last twenty-five years can be readily followed from the diagrams given by Dr. F. Watts.

An important contribution to the subject of foliar periodicity in tropical countries is provided by Mr. H. Wright in the Annals of the Royal Botanic Gardens, Peradeniya, vol. ii., part iii., 1905, recording a large number of interesting observations. Contrasting the influence of internal and external factors, two arguments in favour of the former are found in the small number of species that pass through a leafless period each year, and the striking fact that there is not a month in the year when all the deciduous species are in full leaf. On the other hand, since more than half the deciduous species pass through their leafless phase during the dry period from January to March, it is obvious that climate has considerable influence on periodicity. Of the physical factors that produce climate, Mr. Wright attributes the greatest importance to humidity. In this connection, the curves of monthly variations of temperature, rainfall, and humidity placed alongside the curve indicating the number of deciduous species in each month are especially instructive.

A very elaborate discussion of the climate of Beyrout, Syria, has been undertaken by Dr. S. Kostlivy, and published by the Royal Bohemian Society of Sciences. Since the year 1876 the observations have been regularly printed in the year-books of the Austrian Meteorological Service; the discussion in question refers to the twenty-five years 1876–1900. We can only briefly mention some of the principal results of Dr. Kostlivy's valuable work. The yearly variation of the monthly means of atmospheric pressure is considerable; the highest monthly mean was in January, 1898, 30·18 inches; the lowest in July, 1893, 29·70 inches, the mean variation being about half an inch. The highest monthly mean temperature occurs in August, 81°·5, the lowest in January, 55°·4. The absolute extremes were 101°·3, in October, 1898, and 30°·0, in December, 1897. The mean annual rainfall is 35·65 inches; of this amount 59·8 per cent. falls in winter, 18·5 per cent. in spring, 0·7 per cent. in summer, and 21·0 per cent. in autumn. During the whole series of twenty-five years, no rain fell in August in twenty-two cases, and none in July in twenty cases. The greatest fall in twenty-four hours was 5½ inches, in October. Snow is unknown at Beyrout, but hail occurs, on an average, on six or seven days in each year. Fog occurs very rarely; it was only observed on nineteen days during the whole period. The most prevalent wind is from the south-west, being about 31 per cent. of the whole of the wind notations; stormy days occur, on an average, only about seven times a year.

The Meteorological Office has issued its "Annual Summary" for 1905, based upon observations made at 153 stations in the United Kingdom; it contains an interesting account of the conspicuous meteorological occurrences during the year. There was a remarkable absence, after the first three months, of gales which affected any large extent of country; during the three months ending with July no general gale was experienced on our coasts. The most violent storm of the year occurred on March 15; it came on with remarkable suddenness, and at Falmouth one of the gusts reached a velocity of 103 miles. Strong gales were also experienced in the last three months of the year. Rainfall was deficient over the kingdom generally, the loss being from 10 inches to 13 inches at some places; but at several stations in Scotland and Ireland the rainfall was above the average, and at Dungeness an excess of 8 inches was recorded. There was no snowstorm worthy of special mention, although snow was of frequent occurrence in the first months of the year. Thunderstorms were recorded in every month in some part of the country, but the distribution was very irregular. The most remarkable droughts occurred in the winter season; a period of dry weather which set in about the middle of December, 1904, was maintained with but unimportant interruptions until the middle of February, 1905. May was also a very dry month over an extensive region. The maximum temperature recorded was 87°, at Maidenhead, on July 26; there were many readings of 80° and upwards. The lowest temperatures in England occurred about January 19; at Llangammarch Wells a reading of 11° was registered. In Scotland and Ireland the greatest cold was about November 19; Braemar registered 5°. Fog was prevalent in the mornings from about the middle of October; November had also several foggy days, but the worst visitation of the year occurred from December 10–14. An exceedingly high tide swept down the east coast of England on the night of January 6–7, flooding extensive tracts and causing great destruction of property; it was accompanied with a hard north-westerly gale.

An informal address by Dr. A. G. Bell to the Committee on Coinage, Weights, and Measures of the U.S. House of Representatives on February 16, giving an explanation of the reasons why the United States should abandon its heterogeneous systems of weights and measures, is printed in the *National Geographic Magazine*

for March. The committee had under consideration a Bill before Congress proposing that, from July 1, 1908, all the departments of the Government of the United States, in the transaction of business requiring the use of weight and measurement, shall employ and use the weights and measures of the metric system. Dr. Bell gave an exhaustive account of the anomalies of the British systems of measurement in use in the United States. He pointed out that all civilised countries, with the exception of the United States and Great Britain and her colonies, have adopted the simpler and more scientific decimal system. He reminded the committee that the metric system was legalised in the United States in 1866, and that its adoption by a portion of the population had increased the present confusion. By reference to the decimal system of coinage already in use in the States, Dr. Bell provided convincing instances of the simplification possible with it in the conversion of units, and explained that the United States, when it changed from the old system of pounds, shillings, and pence to the present dollars and cents, did not adopt the metric system of weights and measures because the latter, as we know it, did not appear until after the American Coinage Act of 1792. The facts that our whole system of arithmetic is decimal, that no difficulty whatever is experienced by ordinary workmen in the use of the metric system—provided there is no question of converting their measurements—and that the use of the metric system need not mean the use of new tools, were all clearly explained. It is interesting to note, in connection with this Bill before Congress, that the committee on publicity of the Metrological Society, of which Prof. Simon Newcomb is chairman, has circulated a letter urging all persons in favour of the introduction of the metric system to write, and also secure from other friends, as many letters to representatives in Congress as possible, so that they may see that public sentiment is in the direction of the adoption of decimal weights and measures.

In the Proceedings of the American Academy of Arts and Sciences, xli., 24, for February, Mr. B. O. Pierce describes, with diagrams, experiments on the manner of growth of a current in the coil of a nearly closed electromagnet, as influenced by the width of the air gap.

We have received part i. of the Transactions of the English Ceramic Society for the session 1905–6, and notice that, in view of the greatly increased activity of the society, it has become necessary to issue its publications in a serial form, instead of in a single volume at the completion of the session, as was formerly the case. The present number contains five papers read before the society during November and December of last year.

OUR ASTRONOMICAL COLUMN.

Comet 1906c.—The following extension of Dr. E. Strömgren's ephemeris for comet 1906c is taken from Circular No. 88 of the Kiel Centralstelle:—

Ephemeris 12h. Berlin M.T.

1906	α (h. m. s.)	δ (° ′)	log Δ	Brightness
April 10	3 7 6	+13 40	0·2912	0·37
14	3 15 40	+16 19	0·3084	0·31
18	3 23 54	+18 45	0·3249	0·27
22	3 31 52	+20 59	0·3405	0·23
26	3 39 38	+23 4	0·3553	0·20
30	3 47 14	+25 0	0·3693	0·17

Brightness at time of discovery = 1·0 = about mag. 8·0.

This object is now apparently leaving the constellation Aries for that of Taurus, and will pass through the Pleiades group on April 26–27.

In reference to the paragraph on comet 1905c on p. 545, where it was stated that that comet, also, would pass near to the Pleiades, the latter name was given in mistake for the Hyades.

Measurements of Linné during the Total Eclipse of the Moon.—In Circular No. 113 of the Harvard College Observatory, Prof. E. C. Pickering publishes the results of a series of measurements of the bright spot around the lunar crater Linné, made by Mr. R. H. Frost during the total eclipse of the moon which took place on February 8.

These results show that the diameter of the spot began to increase as Linné passed into the earth's shadow, and to decrease rapidly on the return of sunlight to that portion of the moon's surface.

This apparently confirms Prof. W. H. Pickering's theory that the phenomenon is due to the formation and melting of hoar-frost.

The Temperature of the Sun.—An important paper bearing on the question of the temperature of the sun's surface was communicated to the Paris Academy of Sciences by M. Henri Moissan on March 19.

In the course of his well known experiments with the electric furnace, M. Moissan recently succeeded in distilling titanium, and from the temperature therein employed he deduces probable limits for the temperature in that part of the sun's body where, as seen from the solar spectrum, titanium is volatilised.

The temperature of the arc employed has been previously determined as about 3500° C., and, taking into account the uncertainty as to the pressure existing in the solar atmosphere, M. Moissan concludes that the probable temperature varies between Prof. Wilson's estimated value of 6590° C. and the value obtained by M. Violle, viz. 2000° C. to 3000° C., the probability being that the latter value is nearer to the truth (*Comptes rendus*, No. 12).

The Melbourne Observatory.—The thirty-ninth annual report of the work done at Melbourne Observatory deals with the period April 1, 1904, to March 31, 1905, its chief point being a statement of the progress of the work in connection with the Astrographic Chart. To this end the astronomical work has been almost entirely confined to meridian observations and stellar photography.

The catalogue series now totals 1149 satisfactory plates, and is complete, whilst for the second catalogue series 455 plates have been obtained. For the chart series, with single exposures of 60m., 565 plates have been passed, thus completing this part of the work. Four hundred and ninety-five plates, with triple exposures of 30m. each, have also been obtained for the chart.

On March 31, 1905, 317 Sydney and 612 Melbourne plates, containing 177,069 and 206,604 stars respectively, had been measured.

The measurement of the long series of magnetic curves extending back for thirty-seven years was nearly completed when the report was issued, 37,212 day-curves out of about 40,000 having been measured.

Mounting the 60-inch Reflector at Harvard.—An interesting description of the method which is being employed in mounting the late Dr. Common's 60-inch reflector at Harvard College Observatory is given in No. 3, vol. xiv., of *Popular Astronomy*.

Instead of being supported on a solid pier, nearly the whole of the weight of the instrument is borne on a cylindrical steel float partly submerged in a tank of water, and so fitted as to be perfectly steady.

The coudé method of mounting has been employed, so that the observer may remain in a comfortably fitted room and make his observations through an eye-piece which retains a constant position and direction.

Electric motors have been employed to drive the telescope, and, by a number of switches conveniently placed in the observing room, the observer is able to maintain full control over all the necessary adjustments.

BIRD-LIFE AT THE SOUTH ORKNEY ISLANDS.

DURING the years 1903 and 1904 the Scottish National Antarctic Expedition made important ornithological researches in the icy regions of the far south, and also at the remarkably remote island of Diego Alvarez, otherwise Gough Island, in the South Atlantic. In both, extensive collections of birds were made, which were recently described in the pages of the *Ibis*.

The main scene of these investigations was at the South Orkneys, a group of more than a dozen islands lying some 600 miles south-east of the Falklands, and which, though discovered so long ago as 1821, had remained among the least known lands within the South Polar seas. The climate of this archipelago, in spite of its comparatively low latitude (60°–61° S.), is essentially polar, the summer temperature being much the same as in regions 10° further south, while in winter as many as 72° of frost were registered.

On Laurie Island, the second largest (30 square miles) of the group, eleven months were spent by the expedition, including the winter of 1903. During this period a number of interesting and valuable observations were made relating to the native birds (some of them little known), their habits, migrations, nidification, and geographical distribution; while the collections formed enabled me to describe phases previously quite unknown in the plumage of several rare species, and also included the eggs of forms never before obtained.

Only a few birds essayed to winter, but on the return of spring marvellous numbers arrived to spend the summer and to rear their young.

The penguins were by far the most numerous, and were of four kinds. The Adélie (*Pygoscelis adéliae*) was the most abundant, its numbers being estimated at not less than five millions; the ringed (*P. antarctica*), which was previously regarded as nowhere common, evidently has its metropolis at the South Orkneys, for at least one million nested on Laurie Island alone; while the gentoo (*P. papua*) was less numerous, since it here nears the southern limit of its range. Another species, the macaroni penguin (*Catarrhactes chrysolophus*), was found in very small numbers, but it probably breeds somewhere in the archipelago. The three first mentioned species of penguin nested in great "rookeries," some of which contained several millions of inhabitants, and extended as a broad belt for two or three miles over elevated plateaux bordering the sea. Their nests were constructed of small stones deliberately collected one by one, and, on an average, there was a nest to each square yard of the area occupied.

Life in these great bird cities was not altogether a happy one. The penguins are ill-natured and pugnacious birds, and woe betide the citizen who trespassed upon the domain of his neighbours, or the poor unfortunate who had not secured a mate and ventured within the precincts of the rookery. Then the bills of all the birds around were turned against the intruders, and a fearful commotion ensued which generally resulted in a free fight all round, each pair of birds attacking their neighbour, and ended in the rookery becoming a veritable pandemonium, rendered hideous by the harsh screeches of hundreds of thousands of voices. Such squabbles and their consequences, however, were mere trifles when compared with two scourges ever present among the sitting birds. Foremost among these were the savage giant petrels, the greatest of feathered ruffians, which wandered in numbers throughout the community gorging themselves to repletion on the eggs and young forcibly taken from the brooding penguins. The second terror was the Antarctic skua, many of which hovered overhead, like so many harpies, and incessantly swooped down to snatch the same treasures from the much persecuted parents.

When courting, as one of the pictures shows, the enamoured ones elevate their bills and utter their far from musical love songs. They do this in unison, moving their heads backwards and forwards or waving them from side to side all the while.

Next to the penguins, the petrels were the most numerous of the bird inhabitants of the island. Of these, eight species were present, most of which were nesting on the sea cliffs, or on the steep screes springing from their bases. On such sites was discovered the egg of the Cape petrel or pigeon (*Daption capensis*), a bird well known to voyagers for more than two hundred years, yet one which had hitherto succeeded in hiding its plain white egg from the gaze of oologists. Many of the eggs of this bird were found on the ledges of the cliffs, but collecting them was not a pleasant pursuit, for these birds, like some others of their order, have the power of squirting a quantity of evil-smelling oil at intruders, making good marksmanship at 8 feet. Fortunately the giant petrel (*Ossifraga gigantea*), a bird as big as a goose, did not practise this art, otherwise the taking of its egg would indeed have been an ordeal. This species, too, sat close, and when pushed off its nest, which consisted of a great heap of stones, it vomited the

FIG. 1.—Adélie Penguins' Rookery on Graptolite Island

contents of its gorged stomach, and thus lightened was able to take wing. The other species resorting to the island for a summer home and nursery were Wilson's petrel (*Oceanites oceanicus*) and the ice petrel (*Pagodroma nivea*), both of which are very abundant. A single pair of the black-bellied storm petrel (*Fregetta melanogaster*) and their egg were found, and thereby a remarkable extension southwards in the previously known range of this species established. Possibly two other petrels were nesting, namely, the Antarctic and slender-billed fulmars (*Thalassoeca antarctica* and *Priocella glacialoides*), and a whale bird (*Prion banksi*) was seen off the islands.

A tern (*Sterna hirundinacea*), a gull (*Larus dominicanus*), and a skua (*Megalestris antarctica*) nested in the vicinity of the shore, but the latter only was abundant. The blue-faced shag (*Phalacrocorax atriceps*), previously not a well known species in any respect, nested in numbers on islets off the coast; and lastly we found another little known species, namely, the white sheath-bill (*Chionis alba*), a remarkable bird distantly related to both the plovers and the gulls. It was quite common, and took up its quarters amid the nesting penguins, feeding on their dead young and broken eggs; in fact, these birds were

regular scavengers, to which the dung of seals did not come amiss.

The chief food of the millions of penguins and tens of thousands of petrels was the opossum shrimp (*Euphausia antarctica*), and when one remembers the vast numbers of this little crustacean consumed daily by the birds on Laurie Island alone, one can only compare their numbers in the sea with the grains of sand upon its beaches.

The Scottish National Antarctic Expedition is to be heartily congratulated on the excellence and importance of its ornithological work. Mr. Bruce, the leader of the expedition, has presented a complete set of the South Orkneys and other birds collected during the voyage of the *Scotia* to the Royal Scottish Museum, Edinburgh.

Fig. 2.—Ringed Penguins courting (Brown's Bay).

For the loan of the blocks from which the pictures have been reproduced we are indebted to the editors of the *Ibis*.

Wm. Eagle Clarke.

INSTITUTION OF NAVAL ARCHITECTS.

THE annual general meeting of the Institution of Naval Architects was held last week, commencing Wednesday, April 4, and being continued over the following Thursday and Friday. A full programme of twelve papers had been prepared by the secretary, Mr. R. W. Dana. The subjects dealt with were of various interest, vessels fitted with internal combustion motors occupying a good deal of attention. There was, however, no paper on the steam turbine.

On members assembling on the morning of Wednesday, the president, the Right Hon. the Earl of Glasgow, took the chair, and after the usual formal business had been transacted, proceeded to read his annual address. He referred to the launch of the large line-of-battle ship *Dreadnought*, and gave certain figures relating to the Navy Estimates. Reference was made to the proposed experimental tank at Bushy. There had been, he said, a general appeal to members of the institution for financial support, but, as the result of preliminary inquiry, it had been ascertained that a certain proportion of the amount required for building and equipping such a tank would be guaranteed by private firms and public bodies. It was obvious that the condition of shipbuilding at the time the proposals were formerly made did not favour the movement, and it was therefore decided to suspend action. Since the scheme was first mooted, additional private experimental tanks had been either laid down or projected by some of the great shipbuilding firms of the country. Such tanks as these, however, could never supply the need that existed for pure research. The council had therefore decided to call together the committee that had the matter in hand, and ascertain the views of the members on the present position of the scheme, and the prospects of its being brought to a successful conclusion. Should the shipowners of the country be unwilling to subscribe the comparatively small amount needed to build, equip, and maintain such a tank, nothing would remain but to abandon the scheme and dissolve the committee. The president hoped, however, that, before such a conclusion was reached, a fresh effort might be successfully made to carry out upon scientific lines a work of vital importance to the development of naval architecture in this country.

The first paper read was a contribution by Admiral C. C. P. FitzGerald, the subject being the new scouts recently designed for the Royal Navy. Details of these vessels were given, and the subject of naval scouting was discussed both from the strategical and tactical point of view. A discussion followed, in which several naval officers took part, and it was pointed out that the scouts were analogous to the old 36-gun frigates, these being the most powerful ships that could be detached from the fleet without weakening the line of battle.

Sir Edward J. Reed next gave an account of the vessels he had designed for service in the colonies. They were of various descriptions, consisting of both screw and paddle boats, the former being of the ordinary or of the tunnel-screw type, whilst both stern-wheel and side-wheel boats were used on the shallow waters of colonial rivers.

On the second day of the meeting the proceedings opened by Mr. R. E. Froude reading a paper on yacht measurement rules, and the late International Conference on Yacht Rating. Delegates from different countries attended this conference, but America did not send any representatives, a matter which was to be regretted. The French delegates abandoned the position they originally took up, the formula they had brought forward not being pressed. The formula ultimately agreed upon by the conference was

$$\frac{L+B+\frac{1}{2}G+3d+\frac{1}{3}\sqrt{S}-F}{2},$$

where L=length, B=beam, G chain girth, d=girth difference (*i.e.* skin girth minus chain girth), S=sail area, and F=freeboard. The reasons on which the formula was based were set forth in Mr. Froude's paper, and were also dealt with in the discussion by which it was followed.

Two papers on motor-boats followed. The first was by Mr. Linton Hope, and dealt with the speed of motor-boats and their rating for motor purposes, and the second was by Mr. James A. Smith, and was on the design and construction of high-speed motor-boats. These papers were read consecutively, and discussed together. The Marine Motor Association has adopted a formula for rating motor-boats for racing purposes. It is as follows:—

$$(P2/A)+\sqrt{L}=\text{rating},$$

where P=motor-power, A=immersed sectional area at the point of greatest beam, and L=length. Motor-power is obtained by the following formula:—

$$\frac{A\times S\times R}{C}=MP,$$

where A is the total piston area of all cylinders in square inches, S=stroke in feet, R=maximum revolutions per minute, and C is a constant equalling 1000 for 4-cycle and 600 for 2-cycle motors. Mr. Hope gave particulars of a large number of existing motor-boats, and the lines of several of the best known. The most interesting part of his paper, however, was a diagram giving curves of speeds and ratings of a large number of existing boats, the data being obtained either from racing records or trials made specially. Mr. Smith, in his paper, also referred to the methods of handicapping motor-boats by a rating rule, and gave particulars of certain of the best known recent craft of this type. A discussion followed, in the course of which Mr. Froude objected to the formula adopted because it was not homogeneous, as it included as factors both length and area.

At the evening meeting on Thursday an interesting paper was read by Mr. J. E. Thornycroft on gas engines for ship propulsion. Particulars of different types of producers were described and illustrated. A large part of the paper was taken up by a description of the Capitaine system. This consists of a suction producer and a gas engine. It had been fitted into a yacht which took part in the reliability trials at Southampton last year. It had also been fitted in a canal barge which recently made a trip from the Thames through the canal system of England to Birmingham, Manchester, and back to London by way of Oxford. These practical illustrations are considered sufficient proof that the system can be applied to marine propulsion. In the discussion which followed the reading of the paper, the chief point raised was whether bituminous coal could be used in a suction producer. Up to the present anthracite has been the fuel employed, the bituminous coal being subjected to caking in the producer, and thus stopping the working. Mr. Thornycroft stated that Mr. Capitaine was endeavouring to solve this problem, and had already constructed a producer which appeared to answer the purpose.

A paper was next read by Prof. R. S. Weighton, of Newcastle, the subject being the efficiency of surface condensers. In this paper the author described a new form of condenser which was presented to the engineering laboratory of University College, Newcastle, by Messrs. Richardson, Westgarth and Co. Very exhaustive tests had been made, there having been 400 full experiments in all. The results of these were plotted, and given in tables and diagrams accompanying the paper. The condenser is of the surface type, fitted with tubes on the general principle adopted in marine condensers. The tubes are divided into three nests, each nest being placed in a separate compartment. Water circulates through the tubes and the steam amongst them. On entering the first compartment a large part of the steam is condensed in the usual way. In place, however, of allowing the resultant water to flow over all the remaining tubes, it is trapped by means of a diaphragm, and flows at once to a receptacle at the bottom of the condenser. The steam that remains uncondensed flows into the next compartment, and circulates amongst the second nest of tubes; here a further quantity is condensed, and the water again trapped off. Any remaining steam is then condensed in the third compartment. From the voluminous tables attached to the paper it was to be gathered that for a given size of condenser and a given volume of cooling water a much larger quantity of steam could be dealt with in the form of condenser described.

On the last day of the meeting, Friday, April 6, the proceedings commenced with a paper on freeboard rules, the author being Mr. J. Foster King. The paper explained the difference between the British and the German rules in regard to freeboard, the latter allowing a deeper lading than in the case of vessels belonging to this country. For some time past the Board of Trade has been giving attention to this question, and amendments of the load-line tables have been under consideration. The President of the Board of Trade has given his sanction to amended rules and tables, such as are shown by the author in his paper, so as to bring the practice of this country more in conformity with the German rules, thus removing certain disabilities under which ships flying the British flag labour in comparison with German competitors.

A paper by Mr. J. L. Twaddell on the overhead wire cableway as applied to shipbuilding was next read. This system of transporting material on the building slip has been installed at Newcastle under the superintendence of Mr. Twaddell. It takes the place of the more elaborate overhead gantries and electric travelling cranes which have been a marked feature in some of our best equipped shipyards. In some respects the cableway is more flexible and convenient, but the durability of the cables was a point raised during the discussion which followed the reading of the paper. Experience will show how far this may prove a defect in the new system.

A paper by Mr. Alex. Murray on the introduction of cranes in shipyards dealt with a subject of a similar nature, and served to illustrate how enterprising German shipbuilders have proved themselves to be in the equipment of their yards. The cantilever cranes and tower cranes erected in one German yard, and illustrated in the paper, are of the most elaborate, and must be also of the most costly, description.

A paper by Mr. Herbert Rowell on oil-tight work in ships of light construction gave particulars of riveting and other details of strengthening surfaces necessary to make steel-plated vessels oil-tight.

The last paper read was by Mr. J. R. Barnett, and gave particulars of a number of steam yachts built within the last twenty-five years.

PHYSICAL AND CHEMICAL CHARACTERS OF HUFF.

AT a recent dinner of the Royal Society Club, Major MacMahon, who represents the Royal Society on the governing body of Winchester College, was so good as to present to the club a quantity of huff—a variety of ale for which the college has long been famous. It is brewed (from malt and hops only) in March of every other year, and is the "duplex visia" or "double beer" of Shakespeare, called "huff cap" in Greene's "Looking Glass for London and England, A.D. 1594," "because," according to the editor, "it inspirited those who drank it to set their caps in a huffing manner." The sample offered to the club was stated to have been ten years in bottle. In appearance it was clear and bright, and of a deep brown colour. Its taste was that of a well-hopped ale of high alcoholic strength.

As several members of the club expressed a desire to know something of the composition of this fine old ale, and in particular as to how it compared in character with

other beers of repute, Major MacMahon was so good as to permit an examination of it to be made in the Government Laboratory.

The results were as follows:—

Specific gravity	1·00873
Original gravity	1·11667
Percentage proof spirit	25·3
Ash—per 100 c.c.	0·465 gram.
Albumenoids—per 100 c.c.	1·001 ,,
Total acid—per 100 c.c. (as acetic) ..	0·18 ,,
Volatile acid—per 100 c.c. ,, ...	0·04 ,,
Specific rotatory power $[\alpha]_{D\,(3\cdot86)}$	+65·4

The alcohol which it yielded by distillation was further examined, with the following results, calculated to proof strength:—

	Per cent.
Esters (as ethyl acetate)	0·0524
Aldehyde	0·004
Higher alcohols	0·240

Huff is the strongest ale of which the Government Laboratory has any record. The nearest to it in point of alcoholic strength and general character is the strong Burton ale known as "Royal Ale." A sample of this, brewed in March, 1905, exported from Liverpool to New York, on analysis in the Government Laboratory gave the following numbers:—

Specific gravity	1·02275
Original gravity	1·10862
Percentage proof spirit	20·2
Ash—per 100 c.c.	0·490 gram.
Albumenoids—per 100 c.c.	0·945 ,,
Total acid—per 100 c.c. (as acetic)...	0·16 ,,
Volatile acid—per 100 c.c. ,, ...	0·036 ,,
Specific rotatory power $[\alpha]_{D\,(3\cdot86)}$	+96·0

Examination of Alcohol—Results Calculated to Proof Strength.

	Per cent.
Esters (as ethyl acetate)	0·022
Aldehyde	Nil
Higher alcohols	0·05

A number of analyses of various ales and stouts, taken from a paper by Mr. A. R. Ling in the *Brewer's Journal* for July, 1903, are appended, and for comparison the results of the examination of huff and the sample of "Royal Ale" are expressed in the same terms.

	Burton Pale Ale (Bottled)	Other Ales A	Other Ales B	Other Ales C	Strong Burton Ale	Dublin Stouts A	Dublin Stouts B	London Stouts A	London Stouts B	"Huff"	"Royal Ale"
Original gravity	1061·3	1052·8	1040·2	1059·0	1108·6	1081·4	1074·1	1072·2	1069·7	1116·67	1108·62
Attenuation gravity	1012·5	1010·4	1008·0	1013·4	1021·6	1018·2	1021·7	1022·8	1020·9	1008·73	1022·75
Absolute alcohol (by weight) ...	5·20	4·57	3·55	4·88	9·36	6·69	5·51	5·20	5·13	11·72	9·25
Total acidity expressed as acetic ...	0·10	0·08	0·07	0·08	0·16	0·20	0·20	0·16	0·14	0·18	0·16
Composition of the Extract.											
Fermented matter	64·75	64·92	64·55	62·93	66·11	63·5	58·7	55·7	56·6	76·96	65·42
Maltose (apparent)	6·05	8·04	8·32	8·74	4·19	5·1	9·6	12·1	12·2	2·38	3·30
Dextrin (apparent)	14·88	13·97	14·06	15·46	14·21	16·9	19·8	14·1	13·4	6·09	14·74
Ash	2·41	2·03	2·14	1·93	1·99	2·0	2·3	2·7	2·2	1·54	1·75
Other substances	11·91	11·04	10·93	10·94	13·50	12·5	9·6	15·4	15·6	13·03	14·79

It will be seen that the appellation of "duplex visia" as applied to huff—a liqueur among beers—is fully justified.

T. E. T.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—An exhibition of 50*l.* a year, tenable for two years, is offered by the governing body of Emmanuel College to an advanced student commencing residence at the college in October. The exhibition will be awarded at the beginning of October. Applications, accompanied by two certificates of good character, should be sent to the Master of Emmanuel not later than October 1.

PROF. E. A. MINCHIN has resigned the Jodrell chair of zoology in University College, London, in view of his appointment to the new chair of protozoology in the University of London. Prof. E. H. Starling has been appointed to the Jodrell chair of physiology at University College. The title of emeritus professor of zoology has been conferred upon Prof. E. Ray Lankester, and that of emeritus professor of civil engineering and surveying on Prof. L. F. Vernon-Harcourt.

AMONG educational benefactions to the colleges of the United States recently announced by *Science* the following may be mentioned. By the will of Dr. W. T. Bacon his estate is given for life to Mrs. Bacon, but at her death the Hartford Medical Society will receive an endowment of 20,000*l.*, and Yale University will receive a part of the residuum of the estate, which is understood to be worth nearly 60,000*l.* It is reported that Mrs. J. B. Stetson has offered to give 20,000*l.* to Stetson University on condition that the present trustees resign. Parsons College, Fairfield, Iowa, recently received 16,000*l.* additional endowment through the will of Colonel Charles Parsons, of St. Louis. This increases the donor's gifts to 29,200*l.* Through the generosity of a Chicago physician (anonymous) and of Dr. Benjamin Taylor Terry, of New York City, Indiana University has received offers of two endowments for pathological research. The income of each fellowship is 150*l.* a year. Both offers are made under the condition that the University provides adequate library and laboratory facilities for such work.

THE Government measure to amend the law relating to education in England and Wales was introduced in the House of Commons on Monday by Mr. Birrell, Minister of Education. It is proposed that the limit of twopence as a rate for secondary education should be removed, that Wales should have a National Education Council, and that complete public control should be secured for all elementary schools receiving State aid. The first clause of the measure proposes that, after January 1, 1908, a school shall not be recognised as a public elementary school unless it is a school provided by the local education authority, so that no elementary school will receive a penny of public money, either from rates or taxes, if it does not become a provided school within the meaning of the Act. Every elementary school receiving rates and grants will thus become at once a provided school; and it will supply the same kind of religious instruction as is now given in provided schools. No catechisms or distinctive religious formularies will be taught, and the conscience clause will operate. This will be the general rule throughout the land. The second clause of the Bill authorises a local education authority, for the purpose of continuing any existing voluntary school as a provided school, to make, with the consent of the Board of Education, arrangements for carrying on a public elementary school with the owners of the schoolhouse, subject to the condition that the education authority must, during the continuance of the agreement, assume the whole responsibility of maintaining the fabric. The cost of this change is estimated at about 260,000*l.* a year. To meet the expenditure involved in these proposals, a further annual grant of 1,000,000*l.* is

to be given, in addition to the existing grants. It is proposed in another part of the Bill to make educational endowments as serviceable as possible for the advancement of education, and to consolidate, simplify, and improve the administrative machinery now in use. No provision is made for the training of teachers. We are not concerned here with the sectarian difficulties which seem to make it hopeless to contemplate a permanent settlement of the question of religious teaching in State schools. The denominationalists regard the provision of religious instruction without creed or catechism, prescribed by the Bill, as opposed to their principles and as an endowment of undenominationalism; therefore they will oppose the measure. The Labour Party, on the other hand, has taken the logical position that State aid should only be given for secular education; and that all religious instruction should be abolished in elementary schools, though moral or ethical teaching could be given based upon the best thoughts and works to be found in the literature and history of the world. Until a common factor of agreement is found in sectarian doctrines, or religious instruction is banished entirely from elementary schools, our educational system promises to continue to be the shuttlecock of opposing parties.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 7, 1905.—"On a Property which holds good for all Groupings of a Normal Distribution of Frequency for Two Variables, with Applications to the Study of Contingency-tables for the Inheritance of Unmeasured Qualities." By G. Udny **Yule**. Communicated by Prof. O. Henrici, F.R.S.

Suppose a contingency-table to have been formed for two characters which have been assigned in some way (not necessarily quantitatively) into classes. Extract from the general contingency-table the frequencies in any four adjacent compartments, and consider these as forming, by themselves, an elementary contingency-table. If the sign of association in all such elementary tetrads be the same, the general contingency-table may be termed *isotropic*. In an isotropic table the sign of the association is the same, not only for every tetrad of adjacent frequencies, but for every set of four frequencies in the compartments common to two rows and two columns. The table remains isotropic in whatever way it may be condensed by grouping together adjacent rows or columns, and if, as an extreme case, it be reduced to four-fold form, the sign of the association in such four-fold table is the same as in the elementary tetrads of the original table. If the rows and columns of an isotropic table be disarranged, the disarrangement is no longer isotropic, but the rows and columns can easily be rearranged in isotropic order. The normal frequency distribution for two variables is isotropic, and possesses the preceding properties. An examination of a number of tables recently published by Prof. Pearson for inheritance of anthropometric measurements (stature, span, forearm and head measurements) shows that all are at least approximately isotropic. On the other hand, the tables for inheritance of eye-colour published by the same writer on the basis of Mr. Galton's material, are, without exception, anisotropic, the divergence from isotropy being of such a kind as would be produced by an excess of frequency in the diagonal compartments of the table corresponding to identity of eye-colour in the two relatives. This excess, in the case of the tables for inheritance in the first degree, is not, however, so great as would be given by the theory of simple alternative inheritance, which accordingly requires modification. The same type of anisotropy appears to hold for the great majority of the tables for inheritance of coat-colour in horses given by Prof. Pearson, and also for the miscellaneous characters, mental and physical, in man, given by him in the Huxley lecture (1903). The marked prevalence of this type of distribution for such very diverse qualities, as compared—so far as investigation has gone—with its complete absence in the case of measured characters, raises the question whether it may not be, in whole or in part, of subjective origin.

The above abstract should have preceded that printed in last week's NATURE (p. 551).

January 18.—"The Growth of the Oocyte in Antedon: a Morphological Study in Cell-Metabolism." By Dr. Gilbert **Chubb**. Communicated by Prof. E. H. Starling, F.R.S.

The paper deals with the growth of the oocyte in *Antedon bifida*, Pennant, and is an attempt to utilise the morphological changes accompanying this process to determine the relative physiological significance of the various cell-structures.

The most striking expression of nucleolar activity consists in the intermittent discharge of spherules into the cytoplasm throughout the growth of the egg. Of these spherules, those discharged during the earlier period of the egg's growth constitute the yolk-nucleus, and both the origin and later behaviour of the latter structure are shown to be due to the progressively changing physical consistency of the cytoplasm. Neither the yolk-nucleus nor the nucleolar matter discharged subsequent to its formation take any part in yolk formation.

Evidence is adduced to show that the chromatin is responsible for the formation of the nucleolus, and that it is in this latter structure that the waste products of cytoplasmic activity undergo their final changes.

The irregularity of the germinal vesicle, so often accepted as an indication of the direct participation of this structure in yolk formation, is shown to be due to purely physical causes. The actual process of yolk formation is shown to be unaccompanied by increased nuclear activity, and to consist merely in the automatic conversion into a more stable form of material deposited in solution in the cytoplasm by the chromatin throughout the entire growth of the egg.

Zoological Society, March 20.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—Descriptions of the species of the coleopterous genus Sciobius: Guy A. K. **Marshall**. The genus comprised forty-one species, of which twenty-two were described as new.—A contribution to the study of evolution based upon the Mexican species of Cnemidophorus: Dr. Hans **Gadow**. The main object of the paper was to trace the correlation of certain variations exhibited by the lizards of this genus, and the environmental, bionomic conditions. To do this a revision of the numerous species of the genus had been necessary, most of the ample material for which had been collected by the author himself. Especial attention had to be paid to an exhaustive study of the surprisingly great variability of certain characters, in particular the changes of the colour-pattern and the scutellation of the collar and of the limbs. The distribution of the many races, into which some of the species seemed to have recently differentiated themselves, was likewise followed up in detail.

Geological Society, March 21.—Mr. Aubrey Strahan, F.R.S., vice-president, in the chair.—The Chalk and Drift in Möen: Rev. Edwin **Hill**. The problem of Möen is to account for portions of Drift, isolated, and seemingly included, in cliffs of Chalk. It has been assumed that these portions occupy dislocations, and that the dislocations were either simultaneous with, or subsequent to, the deposition of the Drift. But cases are here described where Drift is seen to occupy cavities in dislocations, which had been water-worn, and consequently had been produced, before the advent of the Drift. A probable assumption that there were pre-Glacial cliffs similar to the present, with clefts and furrows in the cliffs, which were covered in Glacial times with a mantle of Drift now in course of removal by denudation, explains every variety of Drift-inclusion. Slopes of uniform inclination, which rise from the beach to the bases of the vertical cliffs, appear to be talus-slopes. In reality they are everywhere solid Chalk, with only a skin of débris; this suggests post-Glacial changes in sea-level.—The relations of the Chalk and Boulder-clay near Royston (Hertfordshire): Prof. T. G. **Bonney**. On the uplands south of Royston, Mr. H. B. Woodward has described three sections (Quart. Journ. Geol. Soc., vol. lix., 1903, p. 362), which in his opinion indicate that a great ice-sheet, as it advanced from the north, sheared off large masses of Chalk and mixed them up with its ground- or englacial moraine (the Chalky Boulder-clay). The author points out that this interpretation rests on an hypothesis—namely, that the latter deposit is the direct product of

land-ice—which, as it involves some serious difficulties, cannot yet be taken for granted. That ice is capable of shearing off and thrusting before it large masses of rock is also an hypothesis, for which the author, after doing his best to study ice-work in the field, can find no valid evidence. He maintains that these sections do not suggest the above explanation. At the Pinner's Cross Pit the Boulder-clay is not, strictly speaking, "banked-up" against the Chalk, but occupies a hollow in the Chalk. In the pit south-west of Newsell's Park, a shear-plane can indeed be seen in one face, which, however, is explicable by ordinary faulting. A few yards farther to the south-east, Boulder-clay appears above the floor of the pit, filling an arched cavity. This is, no doubt, a singular position, but there is nothing to show that the Chalk has been thrust over the Clay. The author suggests that, as in Möen, the Clay has been carried down from above into cavities already formed in the Chalk.—Brachiopod homœomorphy: Pygope, Antinomia, Pygites: S. S. **Buckman.** This paper deals with the diphyoid Terebratulæ, of which so many species have borne the name *Terebratula diphya* (Colonna). It is pointed out that this name is pre-Linnean, and can only date from the time when it was revived by L. von Buch in 1834. It appears that *Terebratula diphya* is not the type of the genus Pygope. Reasons are given for taking as the type of Pygope one of the forms of *T. antinomia* which is considered to be the same species as *T. deltoidea*, Val. Then the later generic name Antinomia, Catullo, is discussed. The genus was founded on five species, and one of them is now selected as the type—the genolectotype. This is *A. dilatata*, Catullo, supposed to be equivalent to *Terebratula antinomia*, Catullo, that is, to what is now selected to be the type of that species. In that case the species would bear the name *Antinomia antinomia* (Cat.). But there is yet another series of diphyoids, typified by *Terebratula diphyoides*, d'Orb. It is pointed out that, although the species covered by the name *diphyoides* are very like Pygope as now used, yet they all differ in having particular characters in the preperforate stage—a dorsal ridge and a ventral sulcus.

Royal Microscopical Society, March 21.—Rt. Hon. Sir Ford North, P.C., F.R.S., vice-president, in the chair.—A contribution to our knowledge of the Rotifera of South Africa: C. F. **Rousselet.**—A new form of finder which can be used on any microscope, and by which the object registered on one microscope can be found on any other: J. M. **Coon.**—Some Oribatidæ from Sikkim: N. D. F. **Pearce.** Most of the tropical species were on the average smaller than those found in temperate climes.—The limits of resolving power for the microscope and telescope: E. M. **Nelson.**

Entomological Society, March 21.—Mr. F. Merrifield, president, in the chair.—Six ♂♂ examples of the Pierine genus Eronia with corresponding ♀♀s: Dr. F. A. **Dixey.** Attention was directed to the extreme diversity shown by the ♀♀s in these closely allied species. Dr. Dixey considered that this characteristic was due to the fact that in every instance the ♀ had been diverted from the ordinary aspect of the group by the operation of mimicry, either Müllerian or Batesian. The species of entirely different affinities which had acted presumably as models were associated also with the exhibit.—Two specimens of *Emmelesia unifasciata* which emerged in August last from pupæ which had lain over since the autumn of 1900, thus having passed five seasons in the pupal stage: R. **Adkin.**—Progressive melanism in the Riviera of *Hastula hyerana*: Dr. T. A. **Chapman.** A discussion followed on melanism and its causes.

Physical Society, March 23.—Prof. J. Perry, F.R.S., president, in the chair.—Unilateral electric conductivity over damp surfaces: Prof. F. T. **Trouton.** Some time ago the author noticed a rather perplexing difference in electrical resistance depending on the direction in which the measuring current was passed. The resistance under examination was that of the layer of moisture which adheres to glass when exposed to moist atmospheric conditions. The arrangement in which this resistance measurement was effected was one used for determining the temperature of deposition of dew. For this purpose two parallel wires of platinum were melted on to a glass surface at a small distance apart. The surface could be artificially cooled. A cell and a galvanometer were inserted in series with the two platinum wires. As soon as moisture condensed on the glass the circuit was completed and a current passed, thus permitting the accurate determination of the dew-point. When a delicate galvanometer is used a small current can be detected long before the true dew-point is reached. It is at this stage that the anomalous behaviour in the resistance is found. On passing a current across the glass surface when exposed to ordinary atmospheric conditions, it was found to diminish to a certain minimum value, the amount of which depended on the hygrometric state. On reversal, the current assumed its original value, and then diminished to a minimum as before, and so on for further reversals. In order more conveniently to study the matter with larger currents, tinfoil grids were prepared by pasting strips of tinfoil on to glass plates. The theory put forward to account for the phenomenon depended on the transportation of moisture over the surface by the current. In this way the effective thickness of the layer might be much diminished by a banking up of the moisture along the edge of one of the metallic electrodes.—The construction and use of oscillation valves for rectifying high-frequency electric currents: Prof. J. A. **Fleming.** The author recalled the fact that so far back as 1890, when investigating the Edison effect in glow-lamps, he had shown that the space between the incandescent carbon filament and an insulated metal plate placed in the vacuous bulb possessed a unilateral conductivity, negative electricity being able to pass from the filament to the plate, but not in the opposite direction. This led him to suggest an arrangement of the above kind for separating out or rectifying the oppositely directed currents in an alternating current. This effect was now recognised as due to the copious emission of negative ions or electrons from the incandescent carbon. It was by no means obvious, however, before trial, that any such rectifying arrangement or valve would operate with currents of very high frequency. For example, electrolytic rectifiers such as the aluminium-carbon cell were not available for high-frequency currents because a time element entered into the chemical actions involved. In 1904, however, the author discovered that if the carbon filament in an electric glow-lamp was surrounded with a metal cylinder connected to an insulated terminal by a wire sealed through the bulb, and if the filament was made incandescent by an insulated battery, then between the insulated terminal and the negative pole of the battery a unilateral conductivity existed which was operative with currents of any frequency, and the valve so made might be employed to render electrical oscillations measurable by an ordinary sensitive galvanometer. The author exhibited oscillation valves made on this plan.—The use of the cymometer for the determination of resonance curves: G. B. **Dyke.** The experiments described in the paper were made with a view to the adaptation of the direct-reading cymometer to the delineation of resonance curves and the determination of the logarithmic decrements of wave trains and the resistance of oscillating sparks.

EDINBURGH.

Royal Society, February 19.—Dr R. H. Traquair, vice-president, in the chair.—The elevation of the boiling point of aqueous solutions of electrolytes: Rev. S. M. **Johnston.** The paper contained a detailed account of the method of experiment, and after giving the experimental results in a number of cases, proceeded to examine into reasons for the observed increment in the value of the elevation constant as indicated by theory. When the ratio of the molecular conductivity for a given concentration to the value for infinite dilution was plotted against the elevation constant, the graph for each salt was, up to a certain ionisation, a straight line parallel to the ionisation axis, but changed direction at this point. Arguments were adduced that this increment in the value of the elevation constant was due to hydration; and if this explanation be assumed, the observations gave a means of determining the ionisation, and therefore the concentration, at which hydration commences. Thus for solutions of CdI_2, $LiCl$, NH_4Br, and NH_4I, with concentrations respectively of 1·8, 0·92, 0·74, and 0·7 gram equivalents per litre,

it was calculated that hydration commenced at ionisations (respectively) of 0·103, 0·57, 0·678, and 0·694.—The formation of certain lakes in the Highlands: Dr. L. W. **Collet** and Dr. T. N. **Johnston**; with a note on two small lakes in the Alps. The paper and the appended note dealt with the characters of certain lakes in relation to their origin as rock basins or barrier basins.—The methods of standardising preparations of the suprarenals: Dr. Isabella **Cameron.**

March 5.—Prof. Crum Brown, vice-president, in the chair. The igneous geology of the Bathgate and Linlithgow Hills, part ii., petrography: Dr. J. D. **Falconer.** In this continuation of a former paper the petrography of the igneous rocks was discussed under three heads:—(1) the lavas; (2) the contemporaneous intrusions; (3) the later intrusions, chiefly in the form of dykes and sills, and probably of late Carboniferous age.—Three papers dealing with some of the zoological results of the Scottish National Antarctic Expedition were communicated, namely, the South Orkney Collembola: Prof. G. G. **Carpenter**; the Turbellaria collected by the expedition: Drs. J. F. **Gemmill** and R. T. **Leiper**; and the *Echinorhynchus antarcticus*: Dr. J. **Rennie.** The last paper was an account of a new species of parasitic worm obtained from the stomach of a Weddell whale.

Paris.

Academy of Sciences, April 2.—M. H. Poincaré in the chair.—Photography of the solar protuberances with coloured screens during the eclipse of August 30, 1905: H. **Deslandres** and G. **Blum.** The object of the work was to use coloured screens in order to cut off, as far as possible, all the permanent gaseous radiations of the protuberances. Three screens were used, a green screen transparent from λ 505 to λ 580, a lighter green screen transparent from λ 500 to λ 580, and a yellow screen transparent for the red, orange, and yellow. Owing to the presence of some clouds the scheme could not be carried out completely, but the general results were satisfactory, and the authors recommend the method for use in future eclipses.—The action of the radium emanation on chromogenic bacteria: Ch. **Bouchard** and M. **Balthazard.** There are two groups of chromogenic bacteria; in the first the colouring matter produced remains adhering to the bacterium, in the second the colouring matter becomes diffused throughout the culture medium. The radium emanation is not capable of modifying the chromogenic power of the first group, but exerts a distinct effect on the second group. A detailed study was made of the pyocyanic bacillus, and it was found that, amongst the various biological properties of this organism, the power of secreting pigments was the one most sensible to the action of the radium emanation. The virulence of the organism was also clearly reduced; much larger doses of the emanation were necessary to affect the reproductive power of the organism.—The heart of King Rameses II. (Sesostris): M. **Lortet.** The microscopic characters of the muscle peculiar to the cardiac muscle of the heart were clearly made out.—A new arrangement of the spectroheliograph: G. **Millochau** and M. **Stefanik.** The spectroheliographs at present in use have the disadvantage of registering on the photographic plate all the vibrations produced by the various rolling and rubbing parts used in the construction. In the instrument described an attempt has been made to reduce these effects. Remark on the preceding note: J. **Janssen.**—The analytical reduction of any system of forces in E_n: P. H. **Schoute.**—Hypertranscendental functions: Edmond **Maillet.**—The most probable numerical value of the ratio ϵ/μ_0 of the charge to the mass of the electron in the kathode rays: C. E. **Guye.** A correction is introduced into the usual formula for deducing the ratio of the charge to the mass of the electron, the effect of which is to reduce the difference between the experimental values of Simon and Kaufmann. This result is favourable to the hypothesis of the identity of the electrons which constitute the kathode rays and the β rays of radium.—The influence of compressibility on the formation of drops: H. **Ollivier.** It is shown that the formation of small liquid drops is largely influenced by the elasticity of the walls and by the compressibility of the liquid; the experimental measurements can be applied to measure the latter.—The halogen combinations of thallium: V. **Thomas.** A thermochemical paper.—The action of some alkaloids with respect to pollen tubes: Henri **Coupin.** Most alkaloids have a very toxic action on pollen tubes. Certain alkaloids, which for a given dose are toxic to the tubes, at a greater dilution may actually serve as food.—The action of carbonic acid on the latent life of some dried seeds: Paul **Becquerel.**—A contribution to the physiology of grafting: G. **Rivière** and G. **Bailhache.**—Some larval forms from the collections of the Prince of Monaco: H. **Coutière.**—The isopods of the French Antarctic Expedition: Mlle. Harriet **Richardson.**—The influence of feeding on the value of the urological coefficients and on the mean weight of the molecule elaborated: A. **Desgrez** and J. **Ayrignac.** The experiments were made on twenty-five healthy subjects, and the effects of varying diet studied. The diets included milk alone; milk, eggs, and vegetables; milk and vegetables; mixed diet, with a little meat; mixed diet, with much meat; and an absolutely vegetarian diet. The results are given in tabular form.—Demonstration of the fibrinogenic function of the liver: MM. **Doyon**, Claude **Gautier**, and Albert **Morel.**—The origin and mode of formation of Oolitic iron minerals: Stanislas **Meunier.**

THE GLOSSOPTERIS FLORA.

Catalogue of the Fossil Plants of the Glossopteris Flora in the Department of Geology, British Museum (Natural History); being a Monograph of the Permo-Carboniferous Flora of India and the Southern Hemisphere. Pp. lxxiv+255. By E. A. Newell Arber. (London: The British Museum [Natural History]. Published by Order of the Trustees, 1905.) Price 12s. 6d.

IN this catalogue the author makes "an attempt towards a complete summary of what is at present known on the subject of the Glossopteris Flora," and he may be cordially congratulated on the successful completion of a task both arduous and difficult. Dr. Smith Woodward, the keeper of the department of geology, has very wisely encouraged the production of catalogues, which are in reality monographs of the greatest value to both botanical and geological students. The scattered literature dealing with the Glossopteris flora renders the work of the monographer very heavy, and the nature of much of the material on which he must base his conclusions necessitates considerable self-control and caution.

Mr. Arber's introduction treats of the Glossopteris flora under three heads:—(1) its botanical affinities; (2) its distribution in space; (3) the evidence as to its age and distribution in time. The sediments of Upper Carboniferous and Permian age have yielded a rich supply of fossil plants in both hemispheres; but in the case of India, Australia, South Africa, and South America the difficulty of drawing a satisfactory line between the Carboniferous and Permian strata has forced geologists to adopt the term Permo-Carboniferous for the plant-bearing beds of India and more southern lands. In these Permo-Carboniferous strata the genus Glossopteris is the most abundant fossil, and for this reason the southern vegetation which flourished during the epoch between the Lower Carboniferous and Triassic periods has been designated the Glossopteris flora. It has long been recognised that the Glossopteris flora differs in too many respects from the northern flora of the same geological age to justify the belief, which was formerly held, as to the world-wide distribution in the latter part of the Palæozoic era of the vegetation which is represented by the rich stores of fossils in the American and European Coal-measures. The approximate distribution of the plants of the two provinces is clearly shown in the maps published by Mr. Arber (p. xix.).

One very serious difficulty in the way of giving a satisfactory botanical account of the Glossopteris flora is the lack of petrified material, and, in the case of nearly all the genera, the absence of fertile leaves or shoots. The genus Calamites, represented by several distinct types in the northern flora, has not so far been recognised in the Glossopteris flora; in its place occur Phyllotheca and Schizoneura, two representatives of the Equisetales about which our information is still very incomplete. Both genera are adequately treated by Mr. Arber, but the botanist, however thorough the treatment, cannot help being made aware of the insufficiency of the material at his disposal. The genus Sphenophyllum affords another example of a characteristic northern type which can hardly be considered a true member of the Glossopteris flora. It is true, as Mr. Arber points out, that Prof. Zeiller has shown good reason for referring the Indian specimens, for which Royle in 1833 instituted the genus Trizygia, to Sphenophyllum. Mr. Arber figures a fragment from Natal as Sphenophyllum sp., but the specimen is too imperfect to serve as satisfactory evidence of the existence of the genus in South Africa. In the case of plants with fern-like fronds we cannot speak with any confidence as to their botanical position.

The simple tongue-shaped leaves with a distinct mid-rib and anastomosing secondary veins, which Brongniart named Glossopteris and placed among the ferns, have never been found, in spite of their extraordinary abundance, with sori or sporangia. A recent discovery by Mr. Arber affords the first satisfactory clue to the nature of the sporophylls. The fronds of Glossopteris are occasionally found in association with smaller scale-leaves, and on these groups of sporangium-like organs have been detected. These bodies are considered, on the whole, to exhibit a greater resemblance to the microspores of recent cycads than to the sporangia of ferns. The palæobotanist who describes specimens of Glossopteris is compelled to face the problem of recognising specific characters among the numerous leaf-forms, but if he knows anything of recent ferns he must admit that he has undertaken an impossible task. Mr. Arber, with the conscientious care which characterises his work, has grappled with this difficulty, and his synopsis of species supplies us with the best working scheme so far devised.

Neuropteridium is another southern genus founded on simply pinnate and sterile fronds, which, like Glossopteris and Gangamopteris, must be left as a plant of doubtful position. Among other members of the Glossopteris flora which it has been customary to place among the ferns are Tæniopteris, Sphenopteris, and Pecopteris; but the absence of fertile fronds again sets a limit to our knowledge. One interesting conclusion to be gleaned from the occurrence of certain ferns in the southern Permo-Carboniferous vegetation (*e.g.* Tæniopteris and Cladophlebis) is that the Glossopteris flora includes types which, in the northern hemisphere, are rather Mesozoic than Palæozoic.

Schizoneura, Neuropteridium, and Voltzia (a conifer) also represent other genera which apparently migrated into Europe in early Mesozoic times. Another striking fact is the absence of any members of the lycopodiales in the Glossopteris flora of Australia and India. On the other hand, Lepidodendron, Sigillaria, and some rather obscure specimens referred to Bothrodendron have been found in South Africa and South America. Mr. Arber takes the view that the occurrence of these fossils in South America and South Africa may be accounted for by

migration from the northern flora. It must, however, be borne in mind that lycopodiaceous plants existed in the far south in the Lower Carboniferous epoch.

Another characteristic member of the northern flora, which is not included in lists of plants from Gondwana Land (the name given by Suess to the southern continent which supported the Glossopteris flora), is Cordaites. It is, however, probable that the strap-like linear leaves known as Nœggerathiopsis, which are abundant in the southern Palæozoic province, are in some cases at least generically identical with Cordaites. This opinion, previously expressed by the reviewer, was strengthened by an inspection of some leaves recently discovered by Mr. Leslie which he had an opportunity of seeing last summer at Vereeniging. We have as yet no satisfactory evidence that the Cycadophyta were represented in the true Glossopteris flora. Similarly, we cannot assert with confidence that the few specimens compared by various writers with the existing *Ginkgo biloba* afford any proof of the existence of the ginkgoales. The coniferales did not play a conspicuous part in the southern vegetation; various fragments have been referred to Voltzia and other genera, but such specimens as occur appear to be indistinguishable from northern Triassic and Rhætic forms.

Although recent work has perhaps tended to bring more closely together the northern and southern Permo-Carboniferous floras, there can be no doubt as to the correctness of the view that the later Palæozoic vegetation of India, South America, South Africa, and Australia differed sufficiently from that of the northern hemisphere to justify the recognition of two botanical provinces. The southern flora lacks the richness and variety which characterise the northern; the number of genera is smaller, and in many localities the abundance of Glossopteris—almost to the exclusion of other genera—suggests a greater monotony in the vegetation. To some extent the apparently greater wealth of the northern flora may be the result of exceptionally favourable conditions for the preservation of land plants, but this does not account for the strikingly different facies. The existence of widespread Glacial deposits in India, South Africa, and Australia furnishes us with a probable means of explaining the uniformity in the vegetation of Gondwana Land and the contrast which it presents to that of the northern hemisphere. In the case of many European genera we are able to make use of anatomical characters as an index of conditions of growth, but the almost complete absence of petrified specimens in the southern province compels the admission that we cannot claim to recognise in the plants themselves any satisfactory evidence as to the nature of the climate in which they grew.

We can cordially recommend Mr. Arber's volume as the best and most comprehensive account of the Glossopteris flora which has been written; he has produced a book bearing the impress of wide knowledge and of a well balanced critical faculty, which cannot fail to be of the greatest value to both geologists and botanists.

A. C. Seward.

A GROUP OF TEXT-BOOKS OF PHYSICS.

(1) *The Organised Science Series: (1) First Stage Physiography (Section I.).* Edited by Dr. R. W. Stewart. Pp. xiii+256; diagrams. (London: University Tutorial Press, Ltd., 1905.) Price 2*s.*

(2) *Science Handbooks for Laboratory and Class-room: Elementary Physics (Third Year).* By John N. Brown. Pp. 111+diagrams. (London: Blackie and Son, Ltd., 1905.) Price 2*s.*

(3) *Examples in Physics.* By C. E. Jackson. Pp. vi+172. (London: Methuen and Co., n.d.) Price 2*s.* 6*d.*

(4) *Advanced Examples in Physics.* By A. O. Allen. Pp. 60. (London: Edward Arnold, n.d.) Price 1*s.* 6*d.*

(5) *Physics.* By Charles R. Mann and George R. Twiss. Pp. x+453; illustrated. (Chicago: Scott, Foresman and Co., 1905.) Price 1.25 dollars.

THE stream of physics text-books continues to flow. The large number of institutions in which this subject is now taught probably makes inevitable a corresponding multiplicity in the text-books issued. Each teacher or group of teachers finds something lacking in the books available for his classes, and at the first opportunity a new manual is produced. But besides the stimulus of this thoroughly healthy quest of the ideal, the requirements of examination syllabuses are important factors in giving rise to publication. Each examination has its independent syllabus somewhat arbitrarily selected from the suggestions of the members of a board, meeting in committee, and the result is that every examination is thought to require a special text-book by those who wish to secure a maximum of passes for their pupils at the least expenditure of labour.

(1) Although the latter motive is distinctly present in connection with the first of the books in our list, we must at the same time readily admit that it is a most admirable volume except in name. It is a mystery why one part of chemistry added to two parts of physics should produce "physiography," but of course Dr. Stewart is not responsible for this. The book has been written to meet the requirements of the Board of Education in regard to the examination bearing its name. Dr. Stewart is no novice in the writing of text-books. He is alive to the difficulties which pupils encounter, and he removes them in advance. The outcome is a manual which rises far above the particular purpose for which it was written, and it may be confidently recommended as a very satisfactory introduction to physics and chemistry suitable for school use. It contains a large number of examples, many of which are worked out.

(2) Mr. Brown's handbook on elementary physics forms one of a series issued under the general editorship of Dr. J. G. Kerr. It is intended as a third year's school course, practical and theoretical. The matter is to some extent of the same kind as the physical part of Dr. Stewart's text-book; we cannot, however, bestow the same praise upon it. The theoretical part is very meagre, and, moreover, in

many cases is rather crude, and with the directions for the experiments which constitute the main part we are not well satisfied. Surely in a calorimeter experiment it is not well to have the water so high as 40° C., especially when a thermometer reading to fifths is used; and surely, also, it is bad science to teach a boy that he can ascertain the temperature of a Bunsen flame by heating a 32-gram mass of copper in it and transferring it to a calorimeter. If this is done, is he too young to be shown at the same time that a small bead of copper will get visibly hotter (judging from tint), and that even a very thin platinum wire will *melt* in a Bunsen burner? The temperature found in the experiment with the copper ball is less than 1000° C. The questions at the end of each chapter are the best things in the book. Many are based on phenomena with which the boy will have acquired familiarity in his sports and other amusements, and these will certainly encourage him to take an interest also in more serious pursuits; but the problem on the hanging of a man strikes one as rather too brutal for a school-book.

(3) The volumes by Mr. Jackson and Mr. Allen consist of collections of examples. Those brought together by Mr. Jackson are of an elementary character. There are about 600 classified according to the branches of physics to which they relate, and these are followed by fifty test papers of mixed problems, each paper containing about ten questions. Thus we have here about 1000 questions the order of difficulty of which reaches practically that of the intermediate examination in the University of London. This collection will certainly be welcomed by a large number of teachers under the Board of Education and in technical schools. The advanced questions have been so constructed as to lead to reasonable results. Answers are provided only to the classified questions.

(4) The collection made by Mr. Allen is of a much more advanced character, viz., that of a final pass or honours degree in physics. The problems are selected in the main from examination papers set by the London and Victoria Universities. Answers are given, and these the present reviewer proceeded to test, but he had omitted to observe an introductory note by Prof. W. Stroud:—

"Answers are appended to the problems. This is the only feature of the book I rather regret, but they are inserted in the interests of private pupils. I should be delighted if only some of the answers were *wrong*, so that students (whose notion of working examples is to juggle with the numerics in a question so as to get the numeric in the answer) might be righteously confounded, but I have no hope; for Mr. Allen's carefulness and exactitude are such that in his preface he does not even tell the users of his book that 'any corrections to the answers will be gratefully received.'"

We commend the book as an aid to the simplification of the work of a teacher, but at the same time we hope that it will not encourage him to put altogether aside the labour of compiling his own problems based on his own experiments and study. Such examples are of far greater value both to teacher and pupil.

(5) With the aim which the writers of this volume have set before themselves we have very full sympathy. It is certain that the academic method of teaching physics tends to discourage a certain class of boy from paying any attention to his subject. To remove this fault a less formal method is desirable, especially in schools. Ultimately the youth who desires a sound knowledge must be willing to learn by logical methods, for it is by these *only* that accurate ideas can be acquired. But unless he is a born student his interest must first be aroused. He must be led to see that an intelligible account can be given of the mode of action of many of the puzzling phenomena which surround him; he must learn that things with which he has been familiar are not events isolated completely one from another so that each has no bearing on the other, but that a knowledge of one contributes to his knowledge of another. In this way a desire for further knowledge is awakened.

We have also considerable sympathy with the way in which this aim is carried out. Their book is full of illustrations, largely from half-tone blocks—motor-cars and express trains in full motion, eight-oared shells, *small* engine attached to *short* train, looping the loop, charming children swinging on a gate (so different from the ordinary wood-cut children), photographs of real ripples on a pond, engines, turbines, and other machinery, the lifting-magnet with its five-ton load of iron, mining coal with compressed-air drill these are some that meet the eye as the pages are rapidly turned over. Sometimes, indeed, the application seems rather indirect. Thus a half-tone figure of a man hard at work on the top of a hay-cart is labelled, "Haying: A man cannot work unless he consumes food." But, even in such a case, the picture is clearly intended merely to call up a series of real events, and not to portray any one with brutal accuracy. History is also called upon to contribute; knowledge has only gradually been acquired. The boy gets an idea of its growth; the "heroes" of science are introduced to him (but without portraits!).

All this is excellent, and will work well. Our only regret is that so much accuracy had to be sacrificed in the text in order to carry out the scheme completely. Is not it better, perhaps, to postpone the explanation of some things until a safe foundation for true knowledge has been obtained? The pupil will require to unlearn many of the statements made here, and this will certainly induce a period of distrust. *Some will never unlearn them.* However, the suggestion that a book of this kind might be better curtailed is the only critical one we have to offer.

MANUFACTURE OF ALUMINIUM.

The Production of Aluminium and its Industrial Use. By Adolphe Minet. Translated, with additions, by Leonard Waldo. Pp. vi+266. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 10s. 6*d*. net.

THIS book brings together the theory and practice of the aluminium industry in a complete and readable form. It commences with a more or less

detailed and historical survey of the chemical processes which were employed before the metal was produced upon a commercial scale by the aid of the electric current. The successful chemical processes which were all based upon the reduction of salts of aluminium with sodium and were simply modifications of the method used by Wöhler in 1827, when he discovered the metal, brought first and foremost in their train the remarkable cheapening in the manufacture of sodium; because unless sodium could be obtained at a low cost it was impossible to manufacture aluminium cheaply. However, by purely chemical processes it was never found possible to produce aluminium below about thirty shillings per kilo. In fact, in 1889 the price was 38*s*. per kilo., but at the end of 1891, soon after the advent of successful electrolytic processes, it had fallen to 5*s*., and at the present day it is rather less than 2*s*. per kilo.

Minet describes the electrical and electrolytic methods in chronological order. To the brothers Cowles, of America, belongs the honour of first producing a working furnace in which they were able to obtain alloys of aluminium with other metals, by striking an arc in a mixture of bauxite and oxide of iron or other metal. The Héroult seems to have been the first furnace in which a fused aluminium salt—cryolite—was actually electrolysed on a commercial scale, and modifications of this furnace are at the present day among the most successful which are employed, and the one worked by the British Aluminium Co. at Foyers is a Héroult. The production of aluminium is essentially one of electrolysis, but it is also electrothermic in so far as the passage of the current serves to keep the bath molten. The bath usually consists in the first place of fused cryolite, and as the electrolysis continues the loss of aluminium is replaced by additions of aluminium fluoride or of alumina. If the bath were regenerated by continual additions of cryolite, in time the quantity of sodium fluoride would become excessive, and sodium and not aluminium would be yielded up at the kathode.

Most authorities consider that in a bath which is regenerated with alumina the alumina and not the fluoride undergoes electrolysis. Minet, however, considers that it is the aluminium fluoride which undergoes electrolysis, and that the fluorine given up at the anode continuously reproduces cryolite.

Part ii. deals with "aluminium and its alloys." In this the author deals with the cost of the production of aluminium and its alloys. Aluminium is perhaps of more general use in the form of its alloys than in the pure condition. We see that Minet mentions its use in the pure state for surgical instruments—woe betide these instruments if antisepticised in mercuric chloride.

A few very interesting pages are devoted to the employment of aluminium as a reducing agent, in the production in the pure state of such metals as chromium, vanadium, manganese, &c., and also for welding purposes. Minet states that ingots of chromium weighing 100 kilos. are prepared at Essen in one charge, and the production of this quantity of metal is said to take only twenty-five minutes.

The translator contributes a short appendix upon "Aluminium in the United States." The book may be heartily recommended as a very useful contribution to the subject.

F. M. P.

PETROL MOTOR-CARS.

Motor-car Mechanism and Management. In three parts. Part i. The Petrol Car. By W. Poynter Adams. Pp. x + 174. (London: C. Griffin and Co., Ltd., 1906.) Price 5*s*. net.

THE author states that his object is to put into the hands of owners and drivers of motor-cars in a convenient and handy form some knowledge of the general mechanical principles which ought to be understood by those who drive them.

This idea has been carried out very fairly. The early chapters on the engine and on the various organs are treated in sufficient detail, and although there are a few blemishes and mistakes, these are not of any considerable importance.

When, however, the author deals with a matter which is extremely difficult for the average car-owner or driver to understand—namely, the understanding and care of the electrical accessories, which are now everywhere used—we can have nothing but praise for the very thorough manner in which this very difficult question has been dealt with; in fact, it is evident that the author is a trained electrical engineer, and has consequently been able to approach this subject from the standpoint of one who has had to explain the nature of electrical developments to the ordinary user of electric apparatus. We think the author's short and concise descriptions of the various sources of electrical supply which are now available, his definitions of conductors, insulators, and other electrical terms which must be used to make his explanations intelligible, are so good and so well arranged that they should be read by anyone who wishes to obtain a bird's-eye view of electrical engineering so far as it applies to ordinary users of electric light and power; at any rate, it is certain that the average user of the modern motor-car finds himself very frequently at fault when he has to puzzle out stoppages on the road due more to the failure of his electrical accessories than to any other cause, except perhaps that of the universal bugbear, the care of the pneumatic tyres.

On p. 85, when mentioning the importance of a good compression in order to get economical working of the engine, the author makes statements which are liable to mislead the user when he says that 37 per cent. of the full value of the charge is transformed into useful work, and that if the compression is increased to 100lb. this may be increased to 45 per cent. We find no note correcting this by explaining how this refers to a perfect engine, and that with such forms of internal combustion engines as are used for cars not more than 50 per cent. of such efficiencies are likely to be realised.

At the present day, when so much is being said as to the want of courtesy and consideration for other users of the road by the drivers of motor-cars, the author's remarks from p. 15 to the end ought to be read by everyone who drives a car.

OUR BOOK SHELF.

Our Stellar Universe. By Thomas Edward Heath. Pp. vi+26; with 26 star-charts and stereograms. (London: King, Sell and Olding, 1905.) Price 10s. net.

Whilst most students of astronomy are able to talk glibly of "stellar parallax" and "light-years," few of us are wont to form any persistent, concrete idea of the figures we employ, nor do the usual star-charts assist us in this matter. For this reason we extend a hearty welcome to Mr. Heath's latest effort to portray, as truthfully as the meagre data available will allow, the actual three-dimension character of space.

In his "Road Book to the Stars," which we reviewed in these columns on September 28, 1905, Mr. Heath explained how he had discovered a simple scale on which concrete comparisons of stellar depths could be based, and from that had been led to the construction of stereograms which would give a visual conception of the relative distances.

In the present volume he publishes twenty-six of these stereograms, including the whole of the sky, each one taking in fifty degrees square as seen from the earth. Twenty-six key-maps show these areas without distortion, and near each star disc are placed symbols denoting the magnitude, the spectral type, and the measured, or hypothetical, parallax. The hypothetical diameter of the star in miles, based on the assumption that the light-giving power of the star per unit area is equal to that of the sun, appears in an index, which also gives the data from which the key-maps were plotted and forms a handy and valuable reference table of the 1520 stars included.

In order to render their differences visible on the stereograms, all the parallaxes have been multiplied by 19,000, and where the actual values are unknown Mr. Heath has taken, as a theoretical quantity, the average parallax of the spectral type to which any one belongs.

Even if the stereoscopic appearance does not indicate the actual facts, these stereograms are of great interest and beauty, and should certainly find a place in every school or institution where astronomy is studied. They will, at least, counteract the natural assumption, made when ordinary star-charts, or even the sky itself, are consulted, that the heavens are simply studded with objects which are all in one plane.

For example, looking at No. 7 which shows the area facing xvh R.A. and 45° N. dec. we see η Herculis standing out in the near foreground and Arcturus far removed, whilst the Northern Crown is, at first sight, hardly recognisable owing to the unfamiliar appearance produced by the separation of its stars in the third dimension. W. E. Rolston.

Chapters on Paper-making. Vol. ii. By Clayton Beadle. Pp. vii+174. (London, 17 The Borough, London Bridge: H. H. G. Grattan, 1906.) Price 5s. net.

The object of this volume is "educational"; it is a contribution to paper-making technology, mainly as an aid to the student worker in his work of self-instruction. The author devotes himself to the task of popularising the work of the City and Guilds of London Institute by reproducing the examination papers set in the subject of paper-making in the years 1901–5, and, putting himself in the position of examinee, giving full answers to these questions.

This task is prefaced by the confession that the answers given may be in many cases open to criticism, as it is evident that certain of the subjects formulated as examination questions are in effect "leading questions" in the industry. This, however, is a tribute to the method of the institute, which, if it is to be really "educational," must keep the student mindful of difficulty, that is, of the objective realities of technical work. It is clear to us that the author has exactly appreciated the aims of the examiners in challenging the original faculties of students, and in suggesting, in the form of examination problems, some of the leading lines of progress.

In addition to this, which is the main subject-matter of the volume, the author has included a chapter dealing generally with the much controverted subjects of technical education and industrial research, and a section upon gelatine sizing embodying the results of original investigations.

The book contains a large number of special dissertations which will interest technologists and practical men, and its appeal, therefore, is to a wide circle of readers.

Anales del Museo Nacional de Buenos Aires. Ser. 3, vol. v. Pp. 574; 289 text-figures. (Buenos Aires, 1905.)

The size of this volume is a sufficient proof of the energy with which the study of biology and the related sciences is carried on in the capital of the Argentine Republic, more especially by the professors and officials of the national museum. Two papers in the present issue by Dr. F. Ameghino, the director of the museum, both dealing with the presence of a perforation in the astragalus of certain recent and extinct mammals, have been already mentioned in these columns. The bulk of the volume is, however, occupied by an article by Dr. E. L. Holmberg on the Amyrilidaceæ indigenous to and cultivated in Argentina, and a second, by Mr. F. F. Outes, on the Stone age in Patagonia. In the latter the author describes stone implements of all descriptions, from rude flint flakes and scrapers to beautifully chipped arrow-heads and perfectly spherical "bolas." The Palæolithic, or Pleistocene, implements are all referred to a single epoch. The resemblance of these implements to those found in Europe, North Africa, and North America is very close, although, as might have been expected, the closest similarity is found in the case of the North American types. In the Neolithic epoch, on the other hand, three periods are distinguishable, each indicating a distinct step in advance of its predecessor. Throughout the Neolithic epoch Patagonia presents characteristics in the matter of flint implements distinguishing it from the rest of Argentine territory. The similarity between the Patagonian neoliths and those of the southern and south-eastern United States is surprisingly close, but between the former and those of the western United States a less marked resemblance exists. Apparently some of these stone arrow-heads were used until a very recent date by certain of the Indian tribes.

R. L.

The Natural History of Selborne. By the Rev. Gilbert White, M.A. Re-arranged and classified under subjects by Charles Mosley. (London: Elliot Stock, 1905.) Price 6s. net.

The distinctive feature of this edition of the famous natural history classic is the re-arrangement of the work according to the subjects dealt with. First, there are descriptions of the locality and its physical characteristics, and these are followed by thirteen sections, respectively concerned with meteorology, geology, ethnology, mammals, birds, reptiles, fishes, insects, spiders and mites, worms, botany, superstitions, and a miscellany of subjects. This convenient arrangement will greatly assist naturalists and other students in referring to White's masterpiece.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Existence of Absolute Motion.

THE article of Prof. Schuster's in your number of March 15, entitled "A Plea for Absolute Motion," is very interesting, but I think there are several conceptions contained therein which will not bear analysis. Partly in reference to his article, therefore, but also because the question is such an important one, I think it may be well to consider as definitely as may be what direct observational or experimental evidence we have for a zero point of motion belonging to space alone, and to which all motions of material bodies may be referred.

Not to be entangled in the snare which is as old as human discussion, I define my terms for present use. By space I mean vacuum in the ordinary sense, that which exists in interplanetary space, that to which we approach in our laboratories, nothing more or less. We have good reason to believe that in the visible universe no other kind of space exists. This is not, I believe, Prof. Schuster's use of the word, but I shall try to show that it is the only proper scientific use.

By absolute motion I mean motion considered with reference to this space alone.

The first evidence is furnished by the observed orbits of binary stars. If the velocity of light is dependent on the motion of the source, light which left the star when its motion was toward the earth must of necessity reach us sooner than the light emitted when this approach component of the star's velocity was smaller or negative. The observed orbit would therefore be distorted in a perfectly definite manner. The fact that this distortion is not observed proves that the velocity of light is not dependent upon the velocity of the source, and must therefore depend upon some positional property of space alone.

The conclusion is vividly represented as follows:—Imagine a hollow sphere in space with a light source at its centre. In general, a light wave leaving the centre will not reach all parts of the surface in equal times. There exists, however, *one* motion of the sphere for which this condition is fulfilled, and this state, which is absolutely independent of all existing bodies, has a fundamental claim to be called absolute rest, because it depends on space alone.

Further evidence is furnished by the laws of electrodynamics. The magnetic effect of electric convection is generally considered to be now beyond question. From it we know that the electromagnetic attraction between two like point charges moving together is a function of their velocity. Since there is no relative motion of the two and they may be considered alone in space, the motion is with respect to space alone. The state of absolute rest is found when the electromagnetic attraction is zero for all directions of the line joining the two charges.

The evidence furnished by the Kaufmann experiment on the mass of a rapidly moving electron, indicating as it does a limiting velocity in space, also implies the existence of absolute motion.

The evidence is not so good as in the other cases, because the effect is complicated by the existence of an *outside* magnetic field with reference to which the electron moves.

I foresee Prof. Schuster's objection to the above. What I have considered he will call motion relative to the ether, while his argument was based on space in a philosophical sense. I have carefully avoided the term ether. It seems to me the word has nothing to do with the discussion. The universe, out to the furthermost visible star, is of such a nature as to be traversed by light. With space in any other sense we have nothing whatever to do, because it does not exist in the visible universe. Even if such "space" did exist outside the visible universe, it is difficult to understand how our observational data could have any bearing on the matter.

Finally, if any more argument is necessary to show that the only space we can consider is that which surrounds us in the universe, it might be derived from the fundamental notion of space perception. Our perception of space is brought about through various sensations, sensations which are caused by events which do not take place in a hypothetical space, non-existent so far as we know, but in the real space which surrounds us. Our very use of the word therefore arises out of experience, and to think of another space is to form only what Mr. Spencer would have called "a symbolic conception." Indeed, I fear if this fundamental standpoint of perception were strictly adhered to, those arguing from the standpoint of another space would have great difficulty in making themselves clear. We cannot be too careful, it seems to me, in considering the origin of our fundamental conceptions.

At any rate, real space, as has been pointed out, possesses a positional, or perhaps better a motional, attribute, and so gives us a basis, founded on experience, for a conception of absolute motion.

DANIEL COMSTOCK.

Zürich, Switzerland, April 3.

The Magnetic Inertia of a Charged Conductor in a Field of Force.

I THINK there is, in Another Place, possibly some misunderstanding concerning the inertia of a moving charged conductor due to the magnetic energy set up by its motion. It depends upon the distribution of the electrification, and may vary from a minimum up to infinity. No question of distortion due to high speed is involved, so the theory is quite simple. Say a sphere of radius a has any distribution of surface charge. For simplicity, let it be symmetrical round the axis of motion, so that the surface density is representable by the sum of any number of zonal harmonic distributions. The corresponding magnetic fields follow. Their magnetic energies are all independent, so that the actual magnetic energy is the sum of the separate magnetic energies.

The really practical case, which is also very simple, is when the conductor has a charge Q and moves in a uniform electric field F. Then the surface density is

$$\sigma = Q/4\pi a^2 + 3c F \cos\theta, \qquad (1)$$

where θ is the polar angle. The magnetic force is

$$H = H_1 + H_2 = (Qu/4\pi r^2)\sin\theta + 3cF(a^3u/r^3)\sin\theta\cos\theta. \qquad (2)$$

The magnetic energy is $\Sigma\frac{1}{2}\mu H^2$, and by integration comes to

$$T = \tfrac{1}{2}u^2[\mu Q^2/6\pi a + \tfrac{8}{5}\mu c^2F^2\pi a^3]. \qquad ($$

The magnetic inertia is therefore $m = m_1(1+h)$, where m_1 is the value for the uniform charge, or $m_1 = \mu Q^2/6\pi a$, and

$$h = n^2/15\pi, \quad \text{if } n = (3F)(4\pi a^2 c/Q). \qquad (4)$$

This n is the ratio of the induced electric force at the pole to the undisturbed force. If $n=1$, F is just large enough to make the surface density be zero at one pole. Then $h = 1/47$. This is the increased inertia due to the disturbance of the distribution of the charge. The "equation of motion" under F is

$$FQ = \{m + m_1(1+h)\}\dot{u}, \qquad (5)$$

where m is the mass of the body. The whole is subject to the restriction of small u/v and small acceleration, so that the electric and magnetic fields sensibly travel with the charge. Nor need F be constant in space or in time, provided it does not vary too rapidly in relation to the size of the conductor. In slow motion the magnetic energy is the fraction u^2/v^2 of that part of the electric energy that depends upon the transverse electric force.

April 3. OLIVER HEAVISIDE.

Old Customs and Festivals.

MY mother, now in her eightieth year, was led by a recent article by Sir Norman Lockyer in NATURE to relate some reminiscences of some of the festivals formerly celebrated in Newton-on-Ayr. One of these seems to point to ancient human sacrifices. In *her* mother's school-days, the pupils of Newton-on-Ayr annually elected a king and a queen on Candlemas Day. On "Pase Friday" (Good

Friday) the king and queen, decked with daffadowndillies, were led out to the Newton Moors, where they were solemnly interred in graves dug side by side in a sandy knowe. Hands were clasped through a hole bored in the sand between the graves.

The burial ceremony had disappeared by the time my mother went to school, but the selection of a king and queen still persisted, though in a degenerate form. The pupil who presented the largest sum of money to the teacher on Candlemas Day was crowned king or queen, and the royal health was drunk in toddy provided by the schoolmaster.

I append a list of some of the festivals in vogue in my mother's childhood. Some of them survived until within thirty years ago, but all, with the exception of New Year's Day, are now practically extinct.

Hogmanay (December 31).—Presents demanded.

New Year's Day.—First-footing; exchange of visits; carousal.

Hansel Monday (first Monday after January 1).—Exchange of presents.

Candlemas.—Election of school-king.

Huntygowk [Hunt the Gowk = Cuckoo] (April 1).—Fools' errands, &c.

May Day.—Washing of face in dew to keep freckles away.

St. John's Eve.—Firing of guns by sailors over captains' houses.

Midsummer Fair.—Great cattle-fair on main street of Newton. On this evening, or some other about this season, the herds in the neighbouring village commune of Prestwick built a great bonfire.

Kipper Fair (first Friday after August 13).—Procession of "whipmen" on gaily caparisoned horses. Horse races and gala on Newton Sands. Publication of lampoons. Feasting on kippered salmon and ale.

Hallowe'en (October 31).—The great saturnalia of the year. Stealing of kale-stocks; smashing of doors with same; smoking-out of house dwellers; disguises; turnip lanterns; diving for apples; eating from one common dish; burning nuts, and many other fortune-telling rites.

Martinmas.—Killing of the mairt or mart, the animal the carcase of which was salted down for winter use.

Christmas, Good Friday, and Easter were not observed.

I have not included hiring fairs, ordinary cattle and horse fairs, &c., or the fast days which were quite modern ecclesiastical institutions. I ought, perhaps, to have included the Queen's birthday (May 24), for, even in my boyhood, that day was honoured in such a boisterously loyal manner as compared with the non-observance of the anniversary in most Scottish towns, that I cannot help thinking the bonfire raisers may in part have inherited their enthusiasm from the traditions of some ancient festival. The progress of a blazing boat through the streets of Ayr and Newton was the crowning episode of the day. The boat was stolen from the Newton fishermen, and no combustible property was on that day safe from confiscation.

Chemistry in Rural Secondary Schools.

PROF. MELDOLA has raised an important question on Mr. Dunstan's letter. Speaking of two rural secondary schools, he says that chemistry (with physics) "has been taught with the greatest success" and is "of distinct value in after life." It would be useful to have information about the careers of the individual boys on which he bases his opinion, and the character of the science teaching in the two schools referred to. My experience with young farmers in Essex has led me to think that the chemistry taught in many rural schools has had too little bearing upon the problems of rural life to be of much practical use, and school life is too short to admit of a science being taught as a means of mental discipline unless at the same time the pupils are building up knowledge that is essential to future progress.

The county institution at Chelmsford to which Prof. Meldola alludes includes schools of horticulture and agriculture. Though not secondary schools, it may be useful to state that, while in teaching horticultural students the biologist found it quite possible to get on without the chemist, in teaching agricultural students the chemist could make little progress without the biologist. It was not that chemistry and physics were not taught to all the students, but that the biologist, *quâ* biologist, necessarily possessed both chemical and physical knowledge, while the chemist, *quâ* chemist, knew no biology. In rural secondary schools biology should be an important subject of instruction, most rural industries being more or less biological. But no progress in biology can be made without an adequate knowledge of chemistry and physics, so that it is not a question of whether these sciences should be taught—there can be no possible doubt about that—but how they are taught. The teacher needs to be essentially a biologist, or at any rate to have studied science in a biological atmosphere, *e.g.* in an agricultural college, in order to be able to teach chemistry as a natural science and build up a knowledge of its principles by the study of substances and phenomena that come within the experience of rural life.

To give a concrete case. A common subject of instruction in the chemistry of a rural school is Weldon's process for the recovery of manganese in the manufacture of chlorine. To not one boy in a thousand is the knowledge of this process likely to be useful in after life, unless as cram for an examination. The underlying principles could be just as well illustrated by a study of the process of liming land to neutralise acidity and promote oxidation, a better subject educationally because coming within the boy's own range of experience, and affording knowledge which might be useful to every boy in the school. But how many of the existing rural school science masters possess the knowledge of natural science necessary to deal with it?

Savile Club, W., April 15.

Diurnal Periodicity of Ionisation of Gases.

IN the course of some experiments on the spontaneous ionisation of air and other gases in closed vessels, Mr. N. R. Campbell and I have detected a well marked periodicity in its value. It has two maxima and two minima in each twenty-four hours, the maxima occurring between 8 a.m. and 10 a.m. and between 10 p.m. and 1 a.m. at night, while the minima occur with great regularity at or near 2 p.m. and 4 a.m. The form of the curve drawn for the observations of any single day is, as a rule, sufficiently well marked for the maxima and minima to be apparent, while if the mean of the observations for several days be taken, the form of the resulting curve is unmistakable.

The cause of this periodicity has not, as yet, been determined. A continuous record of the temperature of the laboratory was taken, and it was found to have a simple daily period with a maximum during the day and a very regular minimum at 7 a.m. The temperature fell steadily from 6 p.m. until seven o'clock the following morning, and, as during this interval the ionisation rises to a maximum, falls to a minimum, and then rises to a maximum again, it does not seem possible to connect the variations with temperature.

On the other hand, the variations of atmospheric potential show some striking parallel features. This quantity has a double daily period. Its maxima, like those of the ionisation, are not very well defined, and occur about the same times. The minima in both cases are remarkably constant, and occur at exactly the same hours—2 p.m. and 4 a.m. The irregularities in the atmospheric potential curves are less marked during the night than during the day—an observation which holds also for the ionisation curves. Lastly, this diurnal variation of the atmospheric potential is most marked in February, and it was in the ionisation curves for February that the periodicity was first noticed.

This and other possible causes of the periodicity are at present being investigated, and although the research is necessarily a slow one, we hope soon to be in a position to publish a full account of the work.

ALEX. WOOD.

Cavendish Laboratory, Cambridge, April 9.

New Spot on Jupiter.

ON April 10 I observed Jupiter in sunshine and noted the red spot central at 5h. 43m., longitude = 30°·0. I soon remarked that the north equatorial belt curved abruptly north in the region north of the red spot and hollow, and that at the following end of this slanting attachment there was a very conspicuous dark spot which was quite new to me. It became central at 6h. 58m., longitude = 75°·3, and seemed nearly as plain as the shadow of a satellite.

On April 12 the same region of Jupiter came under review. The red spot was central at 7h. 25m., longitude = 31°·6, and the new north tropical spot at 8h. 33m., longitude = 72°·7. The shadow of the first satellite was projected on the disc at the following end of the dark material forming the south tropical disturbance, and it appeared very little darker than the north tropical spot.

Observations were made on April 10 with 10-inch With-reflector, power about 220, and on April 12 with $12\frac{1}{2}$-inch Calver-reflector, power 315.

During the present opposition of Jupiter the north equatorial and north temperate belts have been extremely faint, but the former recently developed a much deeper tone, and particularly in that section lying north of the red spot. The late outbreak of dark material in the north tropical zone will probably lead to the further intensification of the belts in this region.

It is hardly necessary to suggest that the new marking should be followed as critically and as long as possible during the short period remaining available for such observations before Jupiter's conjunction with the sun. Its rate of motion probably differs little from that of the red spot, and it may be looked for near the planet's central meridian on April 22 at 6h. 48m., April 24 at 8h. 26m., and April 29 at 7h. 37m. W. F. DENNING.

Bristol, April 14.

Oscillation of Flame Cones.

LIKE Prof. Smithells, who endeavoured to explain the phenomena described in Mr. Temple's letter to NATURE (March 29, p. 512), I have made many experiments with gas and air mixed by mechanical means and otherwise (Proc. Roy. Soc., vol. xxiv., and elsewhere), but am unable to agree with his conclusions in this case.

Assuming the mixture ascending the tube to contain 20 per cent. of gas by volume, and the relative densities of the air and gas to be as 1 to 0·5, then the *head* which produces the current is equal to a column of air 4·8 inches (0·4 foot) high, and, disregarding friction, the velocity = $\sqrt{2g\,0{\cdot}4} = 5$ feet per second.

Again, assuming the average absolute temperature of the gases above the flame, when the latter has descended to a depth of 2 feet, to be 1500° F., and the corresponding temperature of the air entering the tube from below to be 520° F., the head becomes 18 inches (1·5 foot) and the velocity = $\sqrt{2g\,1{\cdot}5} = 9{\cdot}8$ feet per second.

According to Mallard and Le Chatelier ("Annales des Mines," 8me Série, Tome iv., p. 326), the maximum velocity of translation of flame in a perfectly motionless mixture of lighting gas and air, contained in a glass tube of similar dimensions to that used by Mr. Temple, is 4 feet per second, but when the mixture is moving or agitated the velocity of translation increases, and may even assume the form of an explosive wave. The maximum velocity of 4 feet per second was obtained when the mixture contained 17·5 per cent. of gas, or, according to the authors, 2·5 per cent. more than is necessary for complete combustion.

Variations in the velocity of the current on the one hand, and of the flame on the other, appear to me to account for all the phenomena observed by Mr. Temple.

62 Park Place, Cardiff. W. GALLOWAY.

Interpretation of Meteorological Records.

IN the interesting discussion of the records of Lander and Smith's instruments at Canterbury (NATURE, March 15) both Dr. Aitken (pp. 485, 533) and Mr. Omond (p. 512) appear to have overlooked the fact that *no rain fell*, but only snow to the depth of more than 1 inch. This snow was mixed with a little hail at the commencement of the storm, but no rain fell as assumed by both your correspondents. The records state that the 0·26 inch of rainfall consisted of *snow melted as it fell*. The first sign of the storm was distant thunder and a darkening of the sky in the north-west. The glycerin barometer commenced its usual sharp rise before the first hail arrived and the storm was directly overhead. It is a curious fact that the rain or snow with a thunderstorm occurs with the sharp barometric *rise*, and not with the *fall* as one might expect. I think the great fall in temperature was due to the snow, and not as described by your correspondents. The rainfall curve did not begin first as suggested by Dr. Aitken, but the barometer as explained above. It is another curious fact that, although my house is the highest here, and has my anemometer on top of 30 feet of iron tubing above roof, and wireless telegraphy aërial 80 feet above street (with which I was busy at time of storm), yet no damage was done; but within 100 yards much lower houses had chimneys and walls thrown down and roofs split, &c., and people were seriously injured. Many houses, windmills, and a church in the district were set on fire. A. LANDER.

Canterbury.

Effect of Solar Eclipse on Fish.

DURING the partial solar eclipse observed in England on August 30, 1905, I was taking a holiday, and fishing in Slapton Ley (Devonshire). All the morning the sport had been indifferent, but as the eclipse neared its maximum the fish suddenly became ravenous, and I took more in that hour than all the rest of the day. My experience was also that of all the other boats out there at the time. The explanation, I presume, would be that the fish imagined night was approaching, and therefore prepared for supper; and as every fisherman knows, the last half-hour, when dusk is gathering, is the time that fish are mostly on the feed, and will readily take any bait.

Sea-sickness and Equilibration of the Eyes.

IN connection with the above subject (p. 511) it may perhaps interest your readers to know that German sailors recommend as a cure for sea-sickness to take a looking-glass and look steadily at your own eyes in it. Every motion of the ship is shared by the looking-glass, and consequently by so doing your own eyes follow the motion of the ship. GEOFFREY MARTIN.

Edinburgh, April 13.

AN ETHNOLOGICAL SURVEY OF THE PHILIPPINES.[1]

WITH characteristic energy, the Americans have made a good beginning with the study of the multifarious natives of the Philippine Islands. Dr. A. E. Jenks, who is chief of the Ethnological Survey for the Philippine Islands, has recently published a substantial volume of 266 pages, and 154 plates, on the Bontoc Igorot, who live in the centre of the northern end of Luzon. Judging from the short account of their physical characters, they, like so many other peoples in the East Indian Archipelago, are a mixture of Indonesians and Proto-Malays; a few are distinctly narrow-headed, about three times as many are broad-headed, and somewhat less than two-thirds are intermediate. The average stature of the men is 5 feet $4\frac{1}{2}$ inches; the women average nearly 7 inches shorter. There is no trace of Negrito blood. The

[1] "The Bontoc Igorot." By Albert Ernest Jenks. Department of the Interior. Ethnological Survey Publications, vol. i. (Manila, 1905.)
"Negritos of Zamabales" By William Allan Reed. *Ibid.*, vol. ii., part i. (Manila, 1904.)
"The Nabaloi Dialect." By Otto Scheerer. *Ibid.*, vol. ii., parts ii., iii. (Manila, 1905.)
"The Bataks of Palawan." By Edward Y. Miller. (Bureau of Public Printing.)

settlement of Bontoc is divided into thirteen wards or political divisions, called *ato*; each has its separate governing council, which can declare war or make peace. Each *ato* contains three kinds of buildings:—(1) public edifices, *fawi* and *pabafunan*, for men and

FIG. 1.—Relative Heights of American, Mixed Blood, and Pure Negrito

boys; (2) similar houses, *ola*, for girls and young women before their permanent marriage; and (3) private houses, *afong*, for families and widows. The *pabafunan* is the home of the various *ato* ceremonies, and is sacred to the male sex; it is the men's club by day and the unmarried men's dormitory; the *fawi* is the council house, and as such is frequented mainly by old men; it is also the skull-house. Dr. Jenks adds a note on the distribution of similar club-houses in Eastern Asia and in Oceania. The *olag* is the dormitory of the girls from the age of two years until they marry, and where they receive their lovers. The *afong* is the only primitive dwelling in the Philippines which is built on the ground, but it contains a small upper storey, and often an attic over this; these are used as store-rooms for cereals. The clothes, ornaments, tattooing utensils, weapons, and the like are described and figured. Of great interest are the accounts of the ordinary domestic operations, especially those connected with the cultivation of rice and the regulation of irrigation; the rules seem to be framed with common-sense, and the people appear to be sufficiently law-abiding. The hill-sides are elaborately terraced; the author doubts whether this art has been borrowed from the Chinese, and inclines to the view that it is indigenous to the East Indian Archipelago, having spread northwards to Japan. Various plants are cultivated, but rice is the most important vegetable product, and in consequence most of the religious ceremonies are in connection with this crop, and take place at stated occasions from seed-sowing to the close of the harvest. Also associated with the importance of rice in the social economy is the employment of *palay*, the unthreshed rice, as a medium of exchange, and a measure of exchange value, for articles bought and sold. *Palay* is at all times a good currency; it is always in demand, being the staple food; it keeps eight or ten years without deterioration; it is portable and infinitely divisible; it is of very stable value, and cannot be counterfeited. Certain villages have special commodities, which are made or produced in superfluity for purposes of barter, such as pots, cloths, salt, pigs. The Igorot has as clear a conception of the relative value of two things bartered as has the civilised man when he buys or sells with money; but whatever he trades, be it a five-cent block of Mayinit salt or seventy-dollar carabao (buffalo), the worth of the article is always calculated on the basis of its value in *palay*, even though the payment is in money. The standard of value of the *palay* currency is the handful—a small bunch of *palay* tied up immediately below the heads of grain; it is about 1 foot long, half head and half straw. On the whole, there is great uniformity in the size of the handful.

The forces of nature are personified in the person of the only god known to the Igorot. He instituted the club-houses and gave rules of conduct, telling people not to lie or steal, and to have but one wife; the home should be kept pure, and all men dwell as brothers.

Enough has been said to show the importance of this work, which deals in a fairly thorough manner with a people about whom nothing was previously known, and who have lived their lives uncontaminated by foreign influence. Dr. Jenks candidly admits that the time at his disposal was insufficient to exhaust the subject, and we can only hope that the work so well begun will be thoroughly completed ere long. The Igorot community seems a very favourable one for an exhaustive sociological study. It would be very desirable for an investigator to make an exhaustive census of each *ato*, recording the whole genealogies of each family, according to the method introduced by Dr. Rivers; by this means accurate information could be obtained concerning the real nature of these wards, the reason for the social and family functions of certain individuals would be made clear, and the system of kinship and the regulation of marriage would be demonstrated.

On a previous occasion we have referred to the memoir on the Negritos of Zambales, by Mr. W. A. Reed, which contains a large number of excellent plates illustrating the general appearance and some of the occupations of these very interesting and primi-

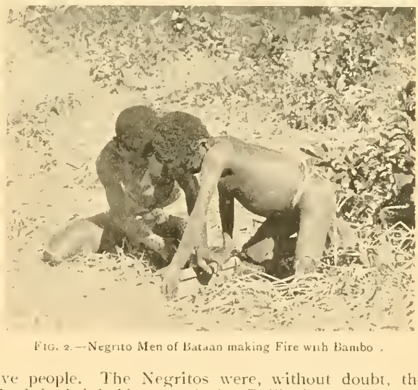

FIG. 2.—Negrito Men of Bataan making Fire with Bambo .

tive people. The Negritos were, without doubt, the aboriginal inhabitants of the Philippines, and they and their congeners in the Malay Peninsula, and in the Andamans, are the relics of one of the most archaic of human stocks. This can only be regarded

as a preliminary study, but, so far as it goes, it has considerable value and interest. The Aeta of Zambales are of a dark chocolate-brown colour, and when pure their hair is woolly; the men have an average height of 5 feet 2 inches; they are broad-headed, the cephalic index of the men averaging 82 and that of the females 86; their noses are exceedingly broad, but they have practically no prognathism. The Negritos studied by the author are not in the most primitive condition, as they have ceased to be purely nomadic hunters, and have taken to a little agriculture. It is to be hoped that Mr. Reed, or some other competent person, will pay especial attention to the real nature of the "scattered families" that wander from one place to another; to discover this it will be necessary to learn the names and relationships of every individual of each community, and this should be done

Fig. 3.—Group of Battak Women, showing Flayed-bark Skirts and Shaved Heads.

for several communities, then we shall learn whether they are clans with mother-right or families with father-right. It is important to map out the hunting grounds, and to record whether they consist of personal property.

Despite the similarity of name, there is no reason to connect the Battak of Palawan with those of Sumatra. They are a wild, hunting folk, who cultivate one or two tuberous plants, and in a few places plant small fields of rice. They gather gums, which they carry to the coast and trade for rice, beads, &c. They wear a scanty garment of bark cloth. They are a mixed Negrito people, and appear to be analogous to the Sakai of the Malay Peninsula. The present paper is only a slight sketch; doubtless these interesting people will be carefully studied in the future. They, like the Negritos of Zambales and elsewhere, are worth special investigation, as they represent the first stage of the passage from a hunting to an agricultural mode of life. No people in this stage of culture has been at all adequately studied from the sociological point of view, and our American colleagues have here a fine opportunity for investigations that are much needed by ethnologists and sociologists.

The term Igorot (the form "Igorrote" is barbarous) is one of those names like Dyak, which has been used so loosely as to be worthless; etymologically it means mountaineer, and therefore can have no racial or even tribal significance. The grammatical study by Dr. Scheerer is concerned with that division of the Igorot who know themselves as Ibaloi and their language as Nabaloi. Contrary to popular opinion, the author can trace no Chinese influence among the people, but, on the other hand, he has found among Ibaloi personal names some that are

Fig. 4.—Ibaloi Women (Girl on Right Side).

pure Japanese words. At present it is impossible to say whether these are more than accidental similarities, or to determine in which direction the loan may have taken place. Nabaloi, like all Philippine dialects, is agglutinative, built up of roots and particles; it belongs to the great Oceanic linguistic stock.

A. C. Haddon.

THE OCEANOGRAPHY OF THE PACIFIC.

A NOTABLE addition to our knowledge of the Pacific Ocean is contained in a paper by Dr. James M. Flint, published as Bulletin No. 55 of the United States National Museum. In the early part of the year 1899 the U.S.S. *Nero*, a steam collier of nearly 5000 tons, which had been purchased for use during the Spanish-American war, was fitted out and dispatched from San Francisco with instructions to survey a route for a telegraph cable between the

United States, the Philippine Islands, and Japan. The ship was in command of Commander Belknap so far as Manila, where he was relieved on account of illness by Lieut.-Commander H. M. Hodges.

As previous surveys had established a satisfactory route so far as the Sandwich Islands, the work of the *Nero* began at Honolulu, whence the ship sailed on May 6, 1899. The instructions were to follow as nearly direct lines as practicable from Honolulu to Midway Island, thence to Guam, and from Guam to Luzon; also from Guam to Japan. Soundings were to be taken on the outward voyage at intervals of 10 miles and 2 miles alternately; temperatures of the air, and surface and bottom of the sea to be recorded; currents noted; samples of bottom to be collected and preserved. The return course was planned to cross the primary route zigzag at angles of forty-five degrees, the sides of the zigzags to be 20 miles in length, and soundings to be taken at the apices. When it is stated that this plan, modified by circumstances chiefly as regards intervals between soundings and detours from the main line in order to develop marked irregularities in the contour of the ocean bed, was effectively carried out, we may agree that the belt 14 miles wide and more than 6000 miles in length has been examined with a thoroughness,

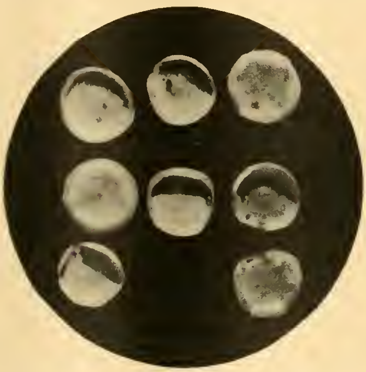

Fig. 1.—Diatom ooze obtained at a depth of 2788 fathoms in latitude 14° 24′ N., and long. 135° 31′ E. *Coscinodiscus rex*, Wallich, magnified 15 diameters.

at least in so far as soundings are concerned, which is unequalled by any survey hitherto made of an ocean tract.

The chief interest as regards depths centres about the region between Guam and Midway Islands. About half-way between the two a plain more than 3000 fathoms from the surface is interrupted by what is apparently a range of mountains, extending over three degrees of longitude, and rising in places to 720 fathoms from the surface. From the western limit of the plain, some 300 miles from this mountain range, the contour is quite irregular until Guam is reached. Extensive detours to north and south of the direct course showed a mountainous region, with peaks rising to 689 fathoms below sea-level and valleys descending to a depth of more than 5000 fathoms. Four soundings below the 5000-fathom line were made in an abyss to which the name "Nero Deep" was given, with the record of 5070, 5101, 5160, and 5269 fathoms. The last sounding is, of course, the deepest on record, being only 66 feet less than 6 statute miles. Its position was lat. 12° 43′ 15″ N., long. 145° 49′ E., or 75 miles E.S.E. of the island of Guam.

From Guam to Yokohama the soundings indicated a continuous range of mountains connecting the Ladrone Islands with the Bonin group.

Another result of importance obtained by the *Nero* is the discovery of diatom ooze as a bottom deposit in tropical waters. Many distinct patches of characteristic diatom ooze were found on the line, especially between Guam and Luzon. Along a line about 300 miles in length, lat. 14° 28′ to 14° 50′ N., and long. 136° to 130° 30′ E., diatom ooze was brought up at thirteen stations from depths between 2432 and 3547 fathoms. Again, between Guam and Midway Islands ooze of a similar kind was obtained at three stations. In all the specimens examined the diatoms belong almost exclusively to a single species, identified by Prof. Mann as *Coscinodiscus rex*, Wallich. We reproduce the figure given in the plates accompanying the paper of "diatom ooze from station 746 (lat. 14° 24′ N., long. 135° 31′ E.), 2788 fathoms. Magnified 15 diameters."

We are unable to do more than direct attention to the two most remarkable discoveries made by this expedition. It is scarcely necessary to add that the table of 2074 soundings, with details of bottom deposits, and a large number of temperature observations, forms in itself an even more valuable contribution to oceanography than the two "records" we have mentioned.

AGRICULTURAL RESEARCH IN INDIA.[1]

THE publication of the first annual report of the Imperial Department of Agriculture of India is little short of an epoch-marking event. As I have said elsewhere, agricultural research has not been wholly neglected in India in the past. Much excellent work has been done by able men working under conditions which were never encouraging. But it has been fitful and uncoordinated, and always at the mercy of uninstructed and unsympathetic officials, whose one canon of criticism has been the solvency of the annual balance-sheet.

India now possesses what it may be hoped before the century has run out will be regarded as the Rothamsted of the East; and the characteristic irony, I might almost say cynicism, of the British race is content that it should owe its foundation in great part to the large-minded munificence of an American gentleman.

The outcome will not be found to-day or to-morrow, but only after years of patient work. The Government of India must not be impatient for immediate results or querulous about current expenditure. That must needs be capital invested, and the return will be the eventual increase of the wealth and prosperity of the population of India.

It now possesses for the first time a real agricultural "headquarters staff." The various experts charged with particular features of the biological campaign are no longer scattered, but are brought together in one institution, where they can work in sympathetic partnership. A glance through the pages of this report is sufficient to reveal the enormous area of the field before them. It may be prudent at the start to make a sustained attack on a few problems rather than to nibble at many.

W. T. Thiselton-Dyer.

[1] Annual Report of the Imperial Department of Agriculture for the year 1904–05. (Calcutta: Government Central Press, 1906.) Price 1*s.* 2*d.*

THE ERUPTION OF VESUVIUS.

THE eruption of Vesuvius has quieted down since last week, though scoriæ and ash continue to be ejected and there still seems to be a slow flow of lava, but in comparison with the activity of the eruption on April 8 the volcano is quiet—until next time. How soon or how long deferred this may be cannot be predicted, but the pause has enabled us to take stock of events and form some estimate of this outburst as compared with previous ones. The most important qualification of earlier reports is in regard to the reported flow of lava through the streets of Ottajano; an outburst of lava on the outer slope of Monte Somma would be remarkable indeed, but later accounts show that none such took place, the damage at Ottajano and San Giuseppe being due to a very heavy fall of ash.

The reports from the Vesuvian Observatory and the definite statement of Messrs. Thos. Cook and Son that their electric tramway has not suffered more than a temporary interruption of traffic, due to the fall of ash, show that no lava flowed in that direction. On the other hand, there seems to have been an extensive outflow into the Atrio del Cavallo and on the south side of the volcano. The lava, which stopped just short of Bosco-Trecase, seems to have reached further than the stream of 1754.

In spite of the prominence given to these lava streams in the daily papers, the eruption seems to have been less remarkable, in this respect, than that of 1895, not to mention others of earlier date, but the volume of volcanic ash produced and scattered over the surrounding country has been very great, and the aspect of the volcano has been materially changed, not only by the addition of a mantle of grey ashes, but also by the destruction of a portion of the cone. The upper part of the funicular railway has been destroyed—blown away, so far as can be made out—in the enlargement of the old crater; the volcano as a whole is noticeably lower than it was, and must have resumed very much the aspect it showed after the eruption of 1822.

The Naples correspondent of the *Times* described in Tuesday's issue the nature and results of the recent eruption. Some extracts from this narrative, dealing with points of scientific interest, are subjoined, with a diary of events abstracted from Press reports.

The most intense activity occurred on the night of Saturday, April 7, when the sides of the cone subsided and the streams of lava, already set free, gained a terrible impulse. The electric phenomena of thunder and lightning, which ordinarily attend any great volcanic convulsion, were then at their height, and the ejection of large blocks from the crater and fiery scoriæ is said to have surpassed anything within the memory of the present generation. The main courses taken by the lava flow seem to have been six in number: towards Ottajano on the north, to San Giuseppe and Terzigno on the east, past Bosco-Trecase to Torre Annunziata on the south, to Torre del Greco and past the observatory on the west. Of these, the most formidable stream was that which descended towards Torre Annunziata, those which deviated towards Torre del Greco and Terzigno being only its branches. At Torre Annunziata the lava stopped just short of the wall of the cemetery outside the town.

The actual area of ground covered by lava cannot yet be conjectured, though it is believed to exceed that covered by all recent eruptions. Next in importance comes the fall of volcanic dust and scoriæ. The direction of this fall varied each day. The worst suffering was inflicted upon Ottajano and San Giuseppe Vesuviano towards the north-east. In both places a large number of houses succumbed to the weight that fell on their roofs. Considerable damage was also done, from the same cause, at Torre del Greco.

During the first three or four days the dust plunged the towns in the immediate vicinity of the volcano into utter darkness, and materially increased the panic that had already set in. Even Naples was in a state of semi-darkness, from which it had hardly emerged on April 12. The roofs and roads seem to be inches deep in an extraordinarily fine, reddish-grey dust, which rises in dense clouds behind every carriage and foot passenger.

In some places the drift of ash seems fully a yard deep; at Ottajano and San Giuseppe in the lightest deposits it must measure three inches. The great danger in both places and, indeed, in most of the towns on the slopes of Vesuvius—would be a heavy rainfall and the formation of mud-torrents, which will more than complete the ruin already begun by the lapilli. At the coast towns, Torre del Greco, Torre Annunziata, Resina, and others, the work of disencumbering the streets and buildings of the lapilli and ashes is already in active progress.

It is difficult to compare the extent of this latest eruption with that of those which have preceded it. Eyewitnesses of both declare it to have been more formidable than that of 1872, which practically destroyed Torre del Greco for the fourth time. The distance to which the ash was carried is so dependent on other atmospheric influences that it cannot constitute a test. In this case the ash seems to have reached Bari and towns on the Adriatic coast. One notable change has been wrought by the eruption. The cone, which has for so long been such a distinctive feature of the mountain, appears to be gone.

The following diary of the eruption is in continuation of that given last week:

April 11. *Vesuvius Observatory.*—Report from Dr. Matteucci: "For brevity's sake I do not give details of my position and that of the carabineers at the observatory, which has been very unpleasant and alarming. Throughout the night and up to 8 o'clock this morning we were completely enveloped in dense showers of dust. As I telegraph everything tends to reduce anxiety, and the seismic instruments show quieter records than yesterday. I shall remain here as long as possible—as long as I have food. If my words could influence the popolation they would be words of encouragement and sympathy in full confidence that Vesuvius will shortly become calmer."

Showers of volcanic ash and other fragmentary products continue to fall. San Giuseppe almost buried in places by mounds of ash and lapilli, and Ottajano in much the same condition. Torre Annunziata remains abandoned, and Torre del Greco is almost deserted. The roads in Naples are covered with a thick layer of volcanic dust, which continues to fall upon the city. The summit of the volcano cannot be seen on account of the dense clouds of steam and dust over it, but it is reported that the shape of the cone has undergone great change, and Dr. Matteucci estimates that the top is now nearly 250 metres lower than before the eruption.

April 12. Seismographs quiet. Volcanic ash has ceased to fall in Naples, Portici, Torre del Greco, and Torre Annunziata, but the shower continues at Ponticelle, St. Anastasia, and Somma.

April 13. No noticeable disturbances. The volcano still surmounted with a dense cloud, which appeared, however, to be disappearing.

April 14.—A shower of ash fell at San Giuseppe Vesuviano and Ottajano to a depth of about 1½ inches. Heavy falls of dust also recorded in the communes of Collina, Strocchia, Boscoreale, Somma, and Ottajano. Slight earthquake shock felt at Ottajano and Terzigno.

April 15.—At 2 p.m. a heavy shower of ash began falling at Ottajano, Boscoreale, Bosco-Trecase, and Torre del Greco, causing intense darkness. There was a slight fall of ashes at Portici, Resina, San Sebastiano, and San Georgio.

April 16. No signs of activity. Seismographs quiet.

April 17.—Conditions normal except for a shower of ash falling on Ottajano and St. Anastasia. Dr. Matteucci reports from the observatory that, with the exception of a few hours, last night was calm. The activity of Vesuvius is limited to a decreased emission of dust, falling in the eastern districts.

NOTES.

We regret to announce that Prof. W. F. R. Weldon, F.R.S., Linacre professor of comparative anatomy, Oxford, died suddenly on Friday last, April 13, at the early age of forty-five.

The University of Berlin has announced the award of a prize of 50*l.* for the best physical or mathematical research presented to the philosophical faculty for the doctor's degree in 1906.

The eighty-ninth annual meeting of the Swiss Scientific Society will be held this year at St. Gall from July 29 to August 1 under the presidency of Dr. Ambühl. The programme will include an excursion to Mt. Sentis.

On behalf of the family of the late Prof. Manuelli, of Modena, Herr T. Waitzfelder has presented the Munich Museum with an interesting collection, in which are some original pieces of apparatus used by Galvani and other Italian investigators, together with some pieces of alchemistic apparatus.

The Schleswig-Holstein Board of Agriculture has elected Dr. Hans Wehnert to succeed Prof. Adolf Emmerling as director of the agricultural chemistry laboratory at Kiel. Dr. Wehnert studied at Brunswick Technical High School and Rostock University, and has had a wide experience as a manufacturer's chemist.

Mr. Edgar R. Waite has resigned his position as zoologist, Australian Museum, Sydney, consequent upon his appointment to the curatorship of the Canterbury Museum, Christchurch, New Zealand. Before he left England for Sydney in 1892 Mr. Waite was an active secretary of the Yorkshire Naturalists' Union, and also editor of the *Naturalist*.

A correspondent of the *Daily Mail*, at Entebbe (Uganda), reports on April 10 that Lieut. Forbes Tulloch, who accompanied the Royal Society's commission sent there to investigate sleeping sickness, has accidentally contracted the disease, and has left for England in charge of Lieut. Gray. The message states that the commission's laboratory has been closed, and all the inoculated monkeys shot to avert further accidents.

A message from a correspondent of the *Times* in Athens states that a telegram from Sparta announces the discovery of the famous sanctuary of Artemis Orthia, before whose altar the Spartan youths were scourged when initiated into the privileges of manhood. The site is on the bank of the Eurotas. Votive offerings of ivory and terra-cotta and quantities of small leaden figures have also been found, as well as pottery, which confirms the belief that this was one of the most ancient Spartan shrines.

The council of the Institution of Naval Architects has nominated Mr. Sidney W. Barnaby to represent that institution on the sectional committee on screw threads and limit gauges of the Engineering Standards Committee in the place of Mr. McFarlane Gray, resigned. The Secretary of State for India has nominated Mr. A. Brereton to represent the India Office on the sectional committee on locomotives in the place of Sir Frederick R. Upcott.

On Thursday next, April 26, Dr. P. Chalmers Mitchell will deliver the first of two lectures at the Royal Institution on "The Digestive Tract in Birds and Mammals." The Friday evening discourses will be resumed on April 27, when Prof. J. W. Gregory will deliver a discourse on "Ore Deposits and their Distribution in Depth." The discourse on May 4 will be given by the Hon. C. A. Parsons, on "The Steam Turbine on Land and at Sea," and on May 11 by Prof. J. H. Poynting, on "Some Astronomical Consequences of the Pressure of Light."

Hermann Schnaus, one of the most thorough and earnest German writers on photography, died on March 14 from paralysis. Beginning life as a bookseller's assistant, first in Jena and afterwards in Bonn, Frankfurt, and Zürich, Schnaus in 1881 entered the photographic publishing firm of Liesegang, at Dusseldorf. After editing *Photographische Archivs*, the first German periodical devoted to photography, Schnaus founded first *Der Amateur-photograph* (now *Photographische Welt*) and afterwards *Appollo*, and in 1905 took over the editorship of the *Photographische Industrie*, to the pages of which he had assiduously contributed from its inception.

From the *Chemiker Zeitung* we learn that the Syndicate of French Sugar Manufacturers, 42 rue du Louvre, Paris, is offering for competition a prize of 100,000 francs for a new application of sugar in the industries, other than the food industry. A condition of the award is that the suggestion shall have been tried in France, and, according to official statistics, have caused an increase in the consumption of sugar in France of at least 100,000 tons in the year. The support of the syndicate is promised in the event of a diminution or the complete abolition of the present sugar tax being necessary for the successful development of the proposed application. Foreigners are not prevented from taking part in the competition.

On March 17, at Baden-Baden, Prof. Adolf Emmerling, director of the agricultural chemistry laboratory of the Board of Agriculture of the province of Schleswig-Holstein, died in his sixty-fourth year. After graduating at Freiburg in 1865, Prof. Emmerling was for nearly four years an assistant in the chemical laboratory of Freiburg University, and for a further two years under Bunsen at Heidelberg; from thence he went to Kiel to direct the work of what was then the agricultural chemistry laboratory of the agricultural Gewerbeverein, which position he held until his death. His numerous scientific researches were published mainly in the *Berichte* of the German Chemical Society and the "Landwirtschaftlichen-Versuchsstationen"; these included a number of new experimental methods and descriptions of new apparatus. Prof. Emmerling, who was a Knight of the Order of the Red Eagle, received the title of professor in 1882, and that of Geheimer Regierungsrat in 1900.

Sir Thomas Browne, the author of "Religio Medici," who lived at Norwich in the middle of the seventeenth century, was buried in the church of St. Peter Mancroft during the early part of the last century. It is believed that his skull was abstracted from the grave and is now preserved at the Norfolk and Norwich Hospital. We learn from the *Times* that recently there has been a considerable expression of opinion in Norwich that the skull ought to be returned to the tomb whence it was taken. The hospital governors on Saturday unanimously passed a resolution agreeing to this course, on condition that the tomb shall be opened in the presence of representatives of the hospital with the view of satisfying them that the remains therein are without a skull.

An earthquake as severe as that of March 17 occurred in South Formosa in the morning of April 14. Kagi was again the town which suffered the most damage. By the disturbance on March 17 1228 persons were killed and

2329 injured, while 5556 houses were totally, and 3383 partially, destroyed. In the present case seven persons were killed and thirty-five injured at Daigo, where 400 buildings were destroyed, while in the Ajensui district the casualties amounted to three killed and fifteen injured, 1191 houses collapsing and 749 being partially wrecked. A Reuter message states that the shock of April 14 was much more severe than that of March 17, and the low death roll, as well as the comparatively small amount of damage done, is to be explained by the fact that the people were more on the alert after their experiences of last month, and that after the havoc caused by the first disturbance there was not much left to destroy.

ARRANGEMENTS have been made to hold a joint meeting of members of the American Institute of Mining Engineers and of the Iron and Steel Institute in London during the week commencing July 23. The Lord Mayor of London has kindly consented to act as chairman of the London reception committee, and a varied programme of entertainments, visits, and excursions will be provided. Meetings for the reading and discussion of papers will be held on the mornings of July 24, 25, and 26, with visits to works in the afternoons. The Lord Mayor will give an evening reception at the Mansion House on July 24. On July 27 the annual dinner of the institute, to which the American visitors are invited, will be held at the Guildhall. Detailed particulars will be issued when the arrangements are further matured. After the meeting in London, a tour will be arranged for the American visitors to York, Middlesbrough, Newcastle-on-Tyne, Glasgow, and Edinburgh. As an alternative excursion a number of the American visitors have been invited by the local reception committee for the summer meeting of the Institution of Mechanical Engineers to take part in the Cardiff meeting of that society.

As previously announced, the annual meeting of the Iron and Steel Institute will be held on May 10–11. At the first meeting the Bessemer gold medal for 1906 will be presented to Mr. Floris Osmond (Paris), and the awards of the Andrew Carnegie gold medal and research scholarships for 1906 will be announced. Among the papers that are expected to be submitted during the meeting are the following:—Influence of silicon, phosphorus, manganese, and aluminium on chill in cast iron, E. Adamson; influence of manganese on iron, Prof. J. O. Arnold; relation between type of fracture and microstructure of steel test pieces, C. O. Bannister; use of oxygen in removing blast furnace obstructions, C. de Schwarz; volume and temperature changes occurring during the cooling of cast iron, Prof. T. Turner. The following reports on work carried out during the past year by holders of Carnegie research scholarships will be submitted:—Hardness of the constituents of iron and steel, Dr. H. C. Boynton; heat treatment of wire, J. Dixon Brunton; quaternary steels, Dr. L. Guillet; influence of carbon on cast iron, W. H. Hatfield; preparation of carbon-free ferromanganese, E. G. Ll. Roberts and E. A. Wraight; deformation and fracture in iron and steel, W. Rosenhain.

THE most important paper in No. 181 of the Proceedings of the American Philosophical Society is one by Miss M. E. Marshall on the anatomy of that aberrant nightjar *Phalacnoptilus nuttali*, the investigation taking into consideration the mutual relationships of the three families usually included in the Caprimulgi.

AMONG the contents of the *Sitzungsberichte* of the Royal Bohemian Academy of Sciences for 1905 may be mentioned an article by Dr. A. Frič on the reptiles of the Bohemian Cretaceous; Montenegro leeches, by Mr. R. Blanchard; the glands of holothurians, by Mr. K. Thon; and the third part of an account of certain fresh-water amphipod crustaceans, by Prof. F. Vejdovský.

IN a paper published in the Proceedings of the Rochester (U.S.A.) Academy of Science (iv., p. 203) Mr. C. L. Sarle concludes that the Silurian fossils described as Arthrophycus and Dædalus, the nature of which has received very various interpretations, are really burrows, Dædalus, at any rate, being probably the work of a sedentary polychætous annelid. The structures form elaborate open spirals of the "Archimedean" type.

THE concluding portion of the catalogue of the marine shells of Victoria, by Messrs. Pritchard and Gatcliff, forms the main portion of the contents of part ii. of vol. xviii. of the Proceedings of the Royal Society of Victoria. Mr. F. Chapman describes a new cephalaspid fish from the Silurian of the colony, referred to the genus Thyestes (Auchenaspis), as *T. magnificus*. The species of the genus hitherto known are all small, but the new one rivals in this respect the majority of the representatives of the typical Cephalaspis.

THE contents of Scientific Investigations (Fisheries, Ireland), No. 7, 1904 (1906), include a report by Mr. E. W. L. Holt on artificial propagation of Salmonidæ in 1904–5; notes on the spawning season of rainbow trout, by Mr. C. Arens (the translation of a paper written for the International Fish Congress at Vienna last year); records of salmon-marking experiments in Ireland from 1902 to 1905, by Mr. A. B. E. Hillas; and statistical information relating to salmon fisheries.

IN a report by Mr. E. D. Sanderson on miscellaneous cotton-insects in Texas, forming Bulletin No. 57 of the Entomological Division of the U.S. Department of Agriculture, attention is directed to the fact that, owing to the ravages of the "boll-weevil," cotton cultivation has entered on a new phase in Texas, and that noxious insects which were formerly ignored have now assumed, in consequence of early and rapid cultivation and reduced acreage, increased importance as factors in the success or otherwise of the crops. Although the investigation is still in its infancy, it is suggested that the remedy for these minor pests will be found in improved methods of cultivation rather than in recourse to poisons.

WE have received separate copies of several papers recently published in the *American Journal of Science*, among which are three by Mr. G. R. Wieland on Cretaceous turtles and tortoises, which have been already noticed in our columns. In a fourth the same author discusses the "pro-embryos" of the fossil cycads of the group Bennettiteæ. Since, with the exception of the archegonia of Cycadinocarpus, no developmental stage has hitherto been described in any fossil plant, the discovery is regarded by the author as one of the highest importance. This paper is dated 1904; while others, by Dr. J. Wortman, on remains of Eocene Primates in the Peabody Museum, were originally published during that and the preceding year. Of more recent date is a revision of the New York Helderbergian crinoids, by Miss M. Talbot, and a review of the fauna of the Palæozoic Chazy Limestone of North America, by Mr. P. E. Raymond.

NOTES on Bahama snakes, by Mr. J. L. Cole, and the description of a new Bahama sea-spider, or pycnogonid, by Mr. T. Barbour, form two of the articles in the March issue of the *American Naturalist*. Mr. W. Stone con-

tributes notes on Pennsylvanian and other reptiles and amphibians, while Prof. M. A. Wilcox commences an account of the anatomy of the limpet, *Acmaea testudinalis*, a subject to which he has for several years devoted attention. The author states that he has endeavoured to make the communication "serve as an introduction to the study of the fascinating but neglected group of Gastropoda." In the sixth article Dr. A. Hollick and Prof. E. C. Jeffrey discuss the affinities of certain Cretaceous plant remains commonly assigned to the genera Dammara and Brachyphyllum. The so-called Dammara is assigned to a new genus of araucarian under the name of Protodammara, while the shoots and branches referred to Brachyphyllum are likewise of an araucarian nature.

The February number of *Le Bambou* contains an article on the identification of species of Phyllostachys, also cultural hints on some of the Arundinarieæ, and notes on the resistance of bamboos to frost in the south of France.

The list of new garden plants for the year 1905, issued as appendix iii., 1906, to the Kew Bulletin, contains, as usual, a large number of orchids, especially species of Cattleya, Cypripedium, Dendrobium, and Odontoglossum. The African continent continues to furnish a considerable proportion of plants, including species of Aloe, Lissochilus, and Polystachya. Messrs. J. Veitch and Sons have introduced a number of Chinese plants, of which the Primulas have attracted attention, particularly *Primula Cockburniana* that bears large orange-scarlet flowers.

A second paper on the Panama Canal, by the Hon. Theodore P. Shonts, chairman of the Isthmian Canal Commission, is published in the February number of the *National Geographic Magazine*. The experiments with foreign labour, arrangements for transportation facilities, and similar matters are fully described.

The report on the state of the ice in the Arctic seas during 1905 has been issued by the Danish Meteorological Institute. The general conclusion drawn is that great masses of ice were disengaged from the firm ice in the north polar regions at an earlier date than usual, and the ice drifted southward faster and in greater quantities than in a normal year.

The February number of the Bulletin of the American Geographical Society is almost entirely devoted to a report of the second annual meeting of the Association of American Geographers, which was held in New York on December 26 and 27 last, under the presidency of Prof. W. M. Davis. About thirty-three papers were communicated, and abstracts of most of these are to be found in the report.

In an article entitled "Winning the West," in the February *National Geographic Magazine*, Mr. C. J. Blanchard gives an interesting account of the extraordinary progress made by the United States Reclamation Service during the last few years. Of the fifty millions of acres which it is estimated can be reclaimed from the desert by irrigation, ten millions have already been made productive, at a cost of some ninety millions of dollars. This area is occupied by a population of about two millions, and every year it returns a harvest valued at more than one hundred and fifty millions of dollars.

We have received a reprint of a paper, published in the Bulletin of the American Geographical Society, by Mr. Daniel T. Macdougal, on the delta of the Rio Colorado. With the help of a map by Mr. Godfrey Sykes, which accompanies the paper, the author describes the complex hydrography of the region between the international boundary and the present head of the Gulf of California. Some useful notes on the climate and flora are added. The paper gains in interest from the fact that the Salton sink and Imperial Valley immediately to the north of the boundary are likely to be greatly modified in the near future by the work of the U.S. Reclamation Service.

The report of the Meteorological Council for 1904–5 (the last year of the administration of the Meteorological Office by that body), which was recently presented to Parliament, contains an interesting account of the operations of the office since its establishment as a department of the Board of Trade under Admiral (then Captain) FitzRoy in 1854. The amount of up-hill work carried out by Admiral FitzRoy, with Mr. T. H. Babington as scientific assistant, and the very few clerks at his disposal was remarkable. His first care was to issue trustworthy instruments to vessels of the navy and mercantile marine, and to collect observations relating to meteorology over the oceans; but pending the receipt and collation of these observations he quickly converted Maury's numerical wind charts into seasonal charts of graphical wind-stars, and issued them in great numbers to seamen. These were soon supplemented by monthly charts, from observations obtained from British ships, combined with those from Maury's charts. Subsequently he collected and collated synchronous observations for both land and sea, from the study of which he was enabled to commence his system of storm signals and weather forecasts by which his name in this country is best known. After his death, in 1865, the management of the office was placed under a committee of the Royal Society, with an increased grant; this body established the self-recording observatories, and under the able administration of Mr. R. H. Scott, as director, the operations of the office were greatly extended. In 1877, on the recommendation of a committee of inquiry, the Meteorological Committee, the services of the members of which were honorary, was replaced by a paid council, with a further increase in the grant. After the lamented death of Prof. Henry Smith in 1883, General (now Sir Richard) Strachey became chairman; his great administrative power and ability in the direction of the constantly increasing work and usefulness of the office (with Mr. Scott, and more recently Mr. Shaw, as secretary), are too well known to require further comment here. The work of all departments, relating to marine meteorology, weather forecasts, and the discussion of the observatory and other records, attained a high degree of excellence, and compares favourably with that performed by any foreign meteorological organisation.

A new method of exactly standardising thermometers between 0° C. and $-4°.0$ C. has been devised by Prof. T. W. Richards and Mr. F. G. Jackson; it is described in the Proceedings of the American Academy (vol. xli., No. 21), and consists in observing the temperatures recorded for the freezing point of dilute hydrochloric acid solutions of known concentration. A table is given of the values for the freezing point of solutions of different strengths. The method should be of special service in standardising thermometers used for accurate physical-chemical researches, particularly in measurements of the freezing point of dilute solutions.

In the Proceedings of the American Academy of Arts and Sciences (vol. xli., No. 20) Prof. Theodore W. Richards and Mr. R. C. Wells deal with the possibility of utilising the

temperature of transition of sodium bromide dihydrate into the anhydrous salt as a fixed point in accurate thermometry. As the result of their investigations they conclude that when the salt is quite pure the transition of the dihydrate into the anhydrous salt takes place at a temperature of 50°.674 C., but that the exact value of the transition point is slightly modified by the presence of traces of impurity. Considerable difficulty is experienced in preparing pure sodium bromide free from sodium chloride; it cannot be obtained by re-crystallising the ordinary bromide, but must be made from pure bromine and pure sodium carbonate. Details are given of the methods used in purifying these materials, the sodium bromide ultimately obtained giving a value of 23.008 for the atomic weight of sodium; this value agrees closely with that recently found for the atomic weight by the same investigators using a method based on the analysis of sodium chloride.

THE variation of the properties of the hydroxyl group of alcohols as the nature and number of the alkyl radicals attached to the carbon atom are varied forms the subject of a suggestive paper by Prof. Louis Henry in No. 12 of the Bulletin of the Royal Academy of Belgium. The observations are of interest both from practical and classificatory standpoints. It is pointed out that as the number of alkyl groups is increased in passing from a primary to a tertiary alcohol, the properties characterising the hydroxyl pass from those associated with the hydroxyl radical of water to those characteristic of the hydroxyl of bases, such as potash. In particular the different behaviour is emphasised of the three classes of alcohols towards the halogen hydrides, towards acetyl chloride, and during esterification by means of hydrogen chloride and a fatty acid. The generalities established can be utilised as a means of predicting the behaviour of the mixed alkyl ethers when subjected to the decomposing action of the halogen acids.

A WELL-ILLUSTRATED price-list of sundials and sundial pedestals has just been issued by Messrs. Newton and Co. Many forms of horizontal and vertical dials, and also pocket dials, are described in the catalogue, which should be seen by anyone who desires to possess a timekeeper of this kind as a reminder of the days when hours were marked by shadows on a dial.

A COPY of the report for 1905 of the Rugby School Natural History Society has been received. It is to be regretted that "a distinct falling off in the keenness of the sections taken as a whole" during 1905 was, according to the preface, noticed by the officers of the society. It may be hoped that the present year will, by its exceptional exhibition of vigour, retrieve the character of what has been a hard-working society.

THE Journal of the Royal Sanitary Institute (vol. xxvii., No. 3) contains the full text of the important series of papers read at the conference on smoke abatement in December, 1905. The list includes the address by Sir W. H. Preece, K.C.B., on factory and trade smoke abatement; and papers on stoking, by Commander W. F. Caborne; on the abatement of smoke from factories, by Dr. S. Rideal; on the artificial production of persistent fog, by the Hon. Rollo Russell; on the destructive effect of smoke in relation to plant life, by Mr. Arthur Rigg; on the work of the Hamburg Smoke Abatement Society, by Mr. J. B. C. Kershaw; on observations on smoke densities, by Mr. J. W. Lovibond; and on the effect of smoke on plant life, by Miss M. Agar.

OUR ASTRONOMICAL COLUMN.

THE CONTINUOUS SPECTRUM OF THE CHROMOSPHERE.—An interesting communication dealing with the question of the existence of a continuous spectrum in the radiations emitted by the chromosphere was communicated to the Paris Academy of Sciences by M. Deslandres on March 26.

M. Deslandres made special preparations for the eclipse in August last in order to determine whether the continuous spectrum (*i.e.* the radiations emitted by solid or liquid *particles*) of the chromosphere is brighter, as bright, or less bright than that of the neighbouring corona. Employing coloured screens, which absorbed the gaseous radiations, he photographed the uneclipsed ring of chromosphere and corona directly, and, in order to determine what proportion of the transmitted radiations was due to the light emitted by the metallic prominences, &c., he simultaneously employed two grating cameras which disclosed the presence and intensity of the latter.

Comparing the images photographed through screens with similar ones obtained in the usual manner by Count de la Baume Pluvinel, it was seen that the former exhibited many striking peculiarities in the large group of prominences in the north-east quadrant. On the screen photographs the prominences were much shorter than on the ordinary photographs, whilst their base and a series of nuclei towards the north were much brighter than the other portions, features not noticeable on the ordinary negatives. Spectrograms of the corona secured at Palma by Dr. W. J. S. Lockyer confirmed the results of this comparison.

M. Deslandres concludes that these prominences did emit a continuous spectrum which was more intense than that of the neighbouring parts of the corona, and were far richer in incandescent particles. A programme for the prosecution of this important research in future eclipses accompanies M. Deslandres's communication (*Comptes rendus*, No. 13).

OBJECTIVE-PRISM DETERMINATIONS OF STELLAR RADIAL VELOCITIES.—Circular No. 110 of the Harvard College Observatory contains a brief description of some results recently obtained with the objective-prism method of determining radial velocities. In this method an exposure is made in the usual way, then the prism is turned through 180° and a similar exposure made, or the telescope may be reversed and the photographic plate turned through 180°. Stars with known velocities serve as standards for the displacement of the corresponding lines in the two spectra.

A reproduction of a spectrogram of the Pleiades, taken on January 29 with the 11-inch Draper telescope, is given in the Circular. On this plate about a dozen stars could be measured, and the probable error in the resulting velocities would be about ± 3.5 km. The scale is $52''.6 = 0.1$ cm., and the exposures were thirty-seven and thirty minutes respectively. On another plate, secured on January 29 with two exposures of about twenty minutes each, about 100 stars could be measured, although a number of them, owing to distortion at the edge of the plate, could only be employed to ascertain the corrections necessary.

In No. 2, vol. xxiii., of the *Astrophysical Journal*, Mr. Geo. C. Comstock discusses a similar method for determining radial velocities, but he proposes two similar direct-vision prisms placed in front of the objective. Formulæ for calculating the velocities from the measures obtained accompany Mr. Comstock's paper.

THE OBSERVATION OF LONG-PERIOD VARIABLES.—In Circular No. 112 of the Harvard College Observatory Prof. Pickering publishes a plea for the organised observations of long-period variable stars, observations which are especially suitable for amateur observers. In order to facilitate this work various catalogues of such stars have already been published by the Harvard observers, and a new one, bringing the results up to date, is now in the printer's hands. When published, copies of this catalogue will be given to all observers who can make use of it.

A number of enlarged copies of Father Hagen's charts of the fainter variables are also being prepared, and will be supplied at cost, or given, to observers qualified to use them. Instructions as to the improved method of making these observations are included in the present Circular.

GEOLOGY IN PRACTICE.[1]

IT will be sufficient to mention such names as the Black Hills, the Bighorn Mountains, the Foxhills and Laramie Range, and the Garden of the Gods to indicate that the preliminary report on the Central Great Plains (1) includes some classical and highly interesting ground. The area covered by the report comprises the greater part of South Dakota, Nebraska, and Kansas, and the eastern part of Colorado and Wyoming an area of no less than 1½ million square miles.

A good deal has already been written about one portion or another of this vast region; the first half of this volume gives a clear generalised account of the stratigraphy and structural geology of the whole; it is, however, by no means a mere abridgment of previously gathered information—it embodies the results of much original work.

From the time when the middle-Cambrian sea washed the Rockies and the adjacent highlands up to the latest physiographic conditions, the geological history of the region is here depicted in a broad manner. One feature of this country at once arrests attention, viz. the repetition in one epoch after another of widespread, uniform conditions of sedimentation—thus the great expanse of Dakota-Lakota sandstone in Cretaceous times, the equally widespread Arikaree sands of the Tertiary, and to-day the sandy alluvial deposits laid down by the rivers when they can no longer bear their load, and spread far and wide as the streams slowly turn from course to course. Less striking, perhaps, but equally widespread, are the argillaceous deposits like the Pierre shale of the Cretaceous. Here, as in other parts of the world, a series of "Red Beds" puzzles the geologist to place a limit to the top of the Carboniferous or the base of the Trias.

But it is not so much for the pure geology that this report will be read as for a guide—a very practical guide—to the sources of underground water. The general conditions governing the underground water system of the Great Plains are simple. A thick succession of alternating sandy and impervious sediments constitutes the rocky floor of the country. These beds are tilted up in the north and west, and dip thence gradually southward and eastward. Water-bearing beds are found in the Cambrian and in every other formation locally up to the recent hills of blown sand; but by far the most important is the Dakota sandstone, which spreads out as a great sheet 150 feet to 300 feet thick beneath the entire area of the plain. This sandstone is underlain by the Red Beds or by the Carboniferous limestone and shale, or, in East Dakota, by the Sioux quartzite; it is overlain by the great mass of clays and shales of the Benton, Niobrara, and Pierre formations. The principal zone of intake lies 4000 feet to 6000 feet above sea-level on the flanks of the Rocky Mountains and the Black Hills; as a result, high pressures are found in wells hundreds of miles from this region.

In this country we trust that the bearing of geological structure upon the amount and quality of water to be obtained in any given area is as well understood as it is across the Atlantic. Yet, although to be "like mother makes it" may express the excellence of a soup, the same can in no wise be said of geo-hydrological literature. We have a curious shyness about graphic modes of presenting information, a diffidence about making unavoidably clear, so that he who runs may read. It is in this direction that the volume under discussion excels, there are no fewer than fourteen maps, and twelve of these bear directly upon water-supply problems.

The landowner, the engineer, the manufacturer, rarely has the time or the requisite special knowledge to sift the information usually conveyed in records of well borings. He cannot afford to spend hours in the endeavour to discover whether the "ratchel" of one sinker is the "muck and rubble" of another, whether "blue bungum" can really be distinguished from "hard bind," or Kimmeridge clay from Gault. The geologist must know these things; what the landowner asks him is, How deep must I sink for water here? and How much may I expect to find? It is true that none but Providence or the "dowser" could answer these questions in terms of precise exactitude, but the report before us proves how much can be done by taking the subject seriously and by the application of graphic methods to focus the geological information in its varied forms into one or more simple images, so that even the "man in the street" can see at a glance what are the possibilities of any particular situation. The maps, in addition to giving the general geology, show also the underground areas occupied by the more important formations separately, and, by means of contours, the depth of the bed-rock beneath superficial deposits, the depth of the

FIG. 1.—"Toadstool Park" in badlands west of Adelia, northern Sioux county, Nebr. Sandstones overlain by Brule clays

most important water-bearing stratum, and the altitude of the head of water, as well as other useful information.

The volume is profusely and beautifully illustrated. Three of the plates, exhibiting forms produced by erosion, have been reproduced to accompany this notice.

Mr. Taff in his report (2) describes the structure and stratigraphy of the two groups of hills, the Arbuckle and Wichita Mountains, which rise abruptly, like islands, from the Red Rock plain in Oklahoma and Indian Territory, a region which lies south-east of that described in the previous report.

These two hill-groups have a common alignment, their axes trending north-westward and south-eastward. Their geological history appears to be identical; underlying the sedimentary rocks in each case are pre-Cambrian granites, granite-porphyries, and aporhyolites—the oldest rock is a gabbro, in the Wichita group. The succeeding Cambrian and Ordovician strata bear no evidence of folding; the period of uplift which has led to the exposure of the igneous pre-Cambrian rocks began in the middle of the Pennsylvanian (Carboniferous) epoch and culminated near its close, before the deposition of the Red Rocks (? Carboniferous or Permian) which in this region constitute the prevailing surface rock.

We are glad to see that the field staff records its appreci-

[1] Reports of the United States Geological Survey. (1) Preliminary Report on the Geology and Underground Water Resources of the Central Great Plains. By N. H. Darton. 1905. (2) Preliminary Report on the Geology of the Arbuckle and Wichita Mountains in Indian Territory and Oklahoma. By J. A. Taff. With an Appendix on Ore Deposits by H. Foster Bain. 1904. (3) The Geology of the Perry Basin in South-eastern Maine. By G. O. Smith and David White. 1905

ation of the arrangement by which the palæontologists were enabled to accompany the party—a very proper plan, and one which in this case greatly facilitated the speed and exactness of correlation and mapping, besides accumulating material for an important monograph on the fossils.

The report contains two geological maps and several views of the scenery. An appendix on the reported ore deposits of the Wichita Mountains, by Mr. H. Foster Bain, should be of use as a warning to prospectors.

(3) Henceforth let no man say there is coal in Perry. For seventy years have the dwellers in south-eastern Maine cherished the hope that coal lay within their borders; and had they not good reason? Perry lies near the edge of a structural basin, and they had been told that the "Perry" beds were Triassic, consequently that coal might be found beneath them; the Canadian Geological Survey had coloured the beds Carboniferous on their map—in spite of Sir William Dawson's diagnosis of the plants—and mining "experts," glancing at the same obscure plant remains, had said, "Here you are, the very thing," and had gladly bidden the people to bore; and they bored, through the Perry beds into the Silurian lavas, but into no coal. Still in hope, the sum of 15,000 dollars was asked for to put down more bore-holes; it was decided, however, first to call in the aid of the U.S. Geological Survey Department, with the result that Messrs. Smith and White were sent to examine the ground. Then, hey presto! the obscurity vanished—a ten days' reconnaissance was enough. There is no coal in the Perry beds, only conglomerate with a little sandstone and shale and interstratified basic lava. Subsequent examination of the badly preserved plants confirmed the age of the beds to be Devonian, probably Chemung, and, incidentally, produced two new generic types. The plants are figured in six plates.

STUDIES OF TEMPERATURE AND PRESSURE OBSERVATIONS.

METEOROLOGISTS will be interested in a paper recently published by Dr. van Rijckevorsel, and entitled "Konstant auftretende secundare Maxima und Minima in dem jährlichen Verlauf der meteorologischen Erscheinungen," part ii. (Rotterdam: Van Hengel, 1905). This is really the second portion of a previous publication, only in this instance the number of stations dealt with is more numerous, and the stations themselves more generally distributed over the earth's surface.

By the method explained in the pamphlet the author has obtained for twenty-two stations the mean annual temperature variations, the resulting curve representing the mean of observations of altogether 3636 years. The author then proceeds to eliminate the annual period of twelve months, and also discusses the residuals. The main result at which he arrives is that, no matter whether he deals with all the observations collectively, with the European stations alone, or with stations collected in north or south hemispheres, there is over the whole earth's surface during twelve months a half-yearly period of temperature the epochs of which are identical. It shows maxima in the beginning of March and September, and two minima in the first days of June and December. Another oscillation which is referred to is one composed of a series of very small maxima and minima.

With regard, however, to the six-monthly oscillation of temperature, a variation which seems to be clearly marked, it is interesting to note that the epochs of maxima seem to pick out the times when the north and south poles of the sun are consecutively turned towards the earth.

As the author finds that stations representing the north and south hemispheres give practically identical results, it would be interesting if he would try an east and west system of grouping of stations, and see if the same result is obtained. In the light of recent work, it seems quite possible, but not probable, that if stations in North-West Africa, South and North America, Honolulu, and Siberia be formed into one group, and the rest of the world into another, the same variation, but of opposite or nearly opposite phase, might be the result. The attempt is well worth trying, since the author has all the material at his hand, and the more stations employed in South America to counterbalance the larger number used and more easily obtained in the European area the better. In this pamphlet curves are given showing the variations derived, and

numerous tables containing the data for stations which possess observations extending more or less continuously over fifty years or more.

In a recent number of the *Meteorologische Zeitschrift* (January) Prof. Hofrat Hann has contributed a new determination of the mean temperature of the earth's atmosphere. In the second edition of his classical "Lehrbuch der Meteorologie," recently noted in this Journal, he gave us the results of a discussion of the material then available, but the publication of more data by Prof. Mohn dealing with the air temperature in the region of the North Pole renders a slight modification of the mean values necessary.

Prof. Mohn has just completed a study of the meteorological observations made during Nansen's memorable North Polar expedition in 1893–6, and has been able to make a new determination of the mean temperatures of the air for the parallels of latitude 60° to 90° north. These new values have enabled Prof. Hann to re-calculate afresh the mean temperature of the whole northern hemisphere, using the results obtained in the investigation of Spitaler for the parallels from 0° to 55° N. The value obtained for the mean of the northern hemisphere was finally 15°·1 C. For the southern hemisphere Prof. Hann had previously determined the value to be 13°·6 C., so that the mean value for the whole earth comes out as 14°·35 C. It is interesting to remark that the northern hemisphere appears to be 1°·5 C. warmer than the southern. Spitaler in 1886 came to a similar conclusion, his figures being:—

Northern hemisphere	15°·4 C.
Southern hemisphere	14°·8 ,,
Whole earth	15°·1 ,,
Excess of N. over S.	0°·6 ,,

Prof. Hann points out that the meteorological observations made during the recent Antarctic expeditions will be of special interest in relation to this question, since a new and better determination of the value for the southern hemisphere is rendered possible.

Attention is directed to the investigation of Prof. Supan, who formed the mean air temperatures into two groups, namely, east and west hemispheres, the dividing lines being 20° W. and 160° E. In this case the eastern hemisphere appears to be the warmer, as can be judged from the following mean temperatures calculated by Prof. Hann:—

	Hemisphere West	Hemisphere East
North Pole to equator ...	14°·6 C. ...	15°·6 C.
North Pole to 30° N. ...	5°·0 ,, ...	5°·4 ,,
30° N. to equator	24°·1 ,, ...	25°·8 ,,
Equator to 30° S.	23°·1 ,, ...	23°·6 ,,
Equator to 50° S.	19°·6 ,, ...	19°·4 ,,

It is only when more southern latitudes are included in the regions investigated that the resulting values give an excess of temperature for the western hemisphere.

In the northern hemisphere the land exceeds the water surface, while the opposite is the case in the southern hemisphere. The figures given above for these districts indicate, therefore, that the land has a capacity for raising the mean temperature of the air, the temperature of the northern in excess of the southern hemisphere being 1°·5 C.

According to General Tilto, there is a greater proportion of land to water in the eastern than in the western hemisphere, the values being

	Per cent. land	Per cent. water
Western Hemisphere (80° N. to 70° S.) ...	17 ...	83
Eastern ,, ,, ,, ...	37 ...	63

From this, therefore, the eastern hemisphere should be warmer than the western. The above figures show that this is actually the case, thus corroborating the deductions made for the relative temperatures of the north and south hemispheres.

In an article which appeared in these columns in 1904 (vol. lxx., p. 177) entitled "A World-wide Barometric See-saw," an account was given of the results of a study by Sir Norman Lockyer and myself of barometric changes of short period, which brought to light the existence of two large regions on the earth's surface, antipodal to one another, which behaved in an inverse manner to each other. In this article a chart was given illustrating the distribution of the different types of pressure variation, and it was pointed out that the further any station was placed from the centres of the two main regions, namely, India and Cordoba, the less the barometric variations were like those of these two regions.

In a recent paper by Dr. Wilhelm Krebs, of Grossflottbek, entitled "Barometrische Ausgleichsbewegung in der Erdatmosphäre" (*Das Weltall*, Jahrgang 6, Heft 8, p. 118), the distribution of this short-period barometric change is discussed, and the author constructs an isophase chart from some of the data published in the original communication from which the above-mentioned article was an abstract.

The method adopted by Dr. Krebs is to call the Indian (Bombay) barometric change 100 per cent., and determine the percentage of the changes in relation to India at nineteen other stations distributed over the earth's surface. This procedure is really not valid, because there are two stations, namely, Bombay and Cordoba, which should both be taken as 100 per cent. each, the one positive and the other negative. Calling Bombay 100 per cent., Dr. Krebs deduces Cordoba as 31 per cent.! Since the Cordoba pressure change is the inverse of that of Bombay, it is difficult to see how the 31 per cent. is obtained. Further, the chart becomes very misleading, for the isophase lines connect up places which have a totally different short-period barometric variation. Thus, for instance, his 70 per cent. line passes through Norway and Sweden, European Russia, Arabia, the Indian Ocean, and Australia. The pressure changes in the latter three regions are closely similar, but all very different from those existing in the first three regions named.

As a matter of fact, the chart already referred to as published previously in this Journal was really an isophase map. In it each of the different signs there adopted, namely, +, +?, −, −?, &c., represented types of barometric changes, the + signs, for instance, representing all places which behaved like India, and therefore represented as 100 per cent. according to Dr. Krebs's method. A more minute differentiation than this seems at present impossible until a much larger number of stations are employed in the survey.

William J. S. Lockyer.

THE MINERAL WEALTH OF ALASKA.

Recent developments have shown that Alaska as a mining field stands in the front rank among the possessions of the United States. Its annual gold production represents a value of some 1,600,000*l*. It produces silver, copper, and coal in considerable quantities, and its recently discovered tin and petroleum deposits are of great promise. During the past year the investigation of the mineral resources of Alaska has been energetically carried on by the United States Geological Survey under adverse conditions, and the Bulletins (Nos. 259, 250, and 236) recently published by Mr. A. H. Brooks, Mr. G. C. Martin, and Mr. C. W. Wright afford striking evidence of the excellent work that is being done in this direction by officers of the survey. Attention has naturally been directed chiefly to the gold placers. The placers of the Seward Peninsula, a field embracing an area of 20,000 square miles, still hold the first place in gold production in Alaska. Seven distinct types of alluvial gold deposits are met with in Alaska:—

(1) Creek placers, at the level of small streams.

(2) Hillside placers, on slopes.

(3) Bench placers, in ancient stream deposits 50 feet to 300 feet above present streams.

(4) Gravel-plain placers, in the coastal plain of Seward Peninsula.

(5) Sea-beach placers, on shore to which waves have access.

(6) Lake-bed placers, in beds of present or ancient lakes.

(7) River-bar placers, on gravel flats near the beds of large streams.

The mining of placer gold in Alaska is carried on during June, July, August, and September; and mining operations are rendered difficult not only by the short available season, but also by the lack of fall in the streams, the poor supply

of water and timber, the half-frozen condition of the gravel, and the high cost of labour and transport. In spite of these obstacles the wide and uniform distribution of alluvial gold, the healthy climate, and the proximity of the phenomenally rich goldfields of the British Yukon territory justify prospecting and mining for gold over so extensive an area. The methods of gravel and placer mining in vogue are well described by Mr. C. W. Purington. Hydraulic methods are the favourites, and the construction of the requisite ditches has gone on with great activity, about a hundred miles being under construction and a similar length in use. In the Porcupine district in south-eastern Alaska, near the international boundary, hydraulicing has proved economical. The gravel is attacked in this way, and sluice-boxes are lain on bed rock, everything being worked into them by the powerful stream from the hydraulic nozzle.

Of the gold-ore deposits in Alaska by far the most important is that of the Alaska-Treadwell mine on the eastern side of Douglas Island. The ore bodies consist of mineralised albite-diorite occurring in the form of intrusive dykes in black slates. The dykes are distributed throughout a zone about 3000 feet in width, extending along the strike for three miles. The ore consists mainly of rock impregnated with pyrites, in part filled by veins of calcite and quartz. The average value of the rock mined is 8*s.* per ton. The ore dykes have been developed along the dip for a distance of about 1000 feet. Hot ascending solutions, possibly of magmatic origin, appear to have been the cause of mineralisation, and the evidence is in favour of only one period of concentration.

None of the metals of the platinum series has yet been found in the Alaska alluvium, but stream tin discovered on the Anikovik River in 1900 has been found over an area of 450 square miles. During the season of 1904 development work on tin lodes was in progress at Lost River and Cape Mountain, and new discoveries of tin lodes were reported at Brooks Mountain, Ears Mountain, and in the Darby Mountains, all in Seward Peninsula.

The attempts to develop petroleum fields in Alaska which were begun in 1901 have been continued, but so far without any commercial production.

Promising surface indications of petroleum have, however, been found in the Controller Bay, Cook Inlet, and Cold Bay fields. Though only a few wells have been bored, Mr. Martin's studies have shown that there is ample justification for further prospecting, and that the Pacific Coast region of Alaska may prove an important source of illuminating oil. In this connection it is of interest to note that the Bering River coal is the best that has yet been found on the Pacific Coast. An average of twelve analyses showed 75·65 per cent. of fixed carbon, 15·06 per cent. of volatile matter, 7·07 per cent. of ash, 1·30 per cent. of moisture, and 1·24 per cent. of sulphur. Coal, mostly of a lignitic character, is also widely distributed in south-western Alaska, whilst the coals of the Cape Lisburne region are of two distinct classes, low-grade bituminous coal of Mesozoic age, and high-grade bituminous coal of Palæozoic age. The former covers an area of 300 square miles with 150 feet of coal in forty or fifty seams, ten of which seem to be of economic importance. The Palæozoic coals are also undeveloped. They occur in limited areas, and the beds are much crumpled and broken, so that mining will be difficult and expensive. The product will, however, probably command as good a price as the best coals shipped to Alaska.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—The electors will proceed to the election of a Sibthorpian professor of rural economy on June 9. The professorship has now been made tenable for life, subject to the liability of the holder to vacate it by deprivation for sufficient cause. The present stipend of the professorship is about 700*l.* a year.

Cambridge.—Applications for the John Lucas Walker studentship, the holder of which must devote himself (or herself) to original research in pathology, are invited, and should be sent, accompanied by references—not testimonials—not later than May 8, to Prof. G. Sims Woodhead, Pathological Laboratory, New Museums, Cambridge, to whom also applications for further information regarding the studentship may be addressed. The studentship is of the annual value of 200*l.* (grants may also be made for assistance and apparatus), and is tenable, under certain conditions, for three years from July 1.

Mr. Earle has been appointed to succeed Sir A. Pedler as Director of Public Instruction in Bengal.

Dr. J. Moeller, of Gratz University, has been appointed professor of pharmacognosia in Vienna University in succession to Prof. von Vogl.

Prof. J. Precht has been appointed to succeed Prof. Dieterici as professor of experimental physics in the Technical High School, Hanover.

Prof. Dr. E. Knoevenagel has been appointed director of the Heidelberg University chemical laboratory in succession to Prof. Theodor Curtius, ex-prosector of the University; while Prof. A. Klages has been deputed to take Prof. Curtius's lectures on experimental organic chemistry.

It has been decided to add to the University of Nancy a new physical institute, toward the cost of which the Government has promised 300,000 francs, while a further contribution of 50,000 francs has also been announced. This will mean that, apart from buildings for the medical faculty, there have been added within quite recent years new institutes for chemistry, electrotechnics, and applied mechanics, whilst the brewing school has been newly organised.

It is announced in *Science* that Mr. Andrew Carnegie has given 400,000*l.*, in addition to previous gifts, for the maintenance of the Carnegie Technical Schools, Pittsburg. From the same source we learn that by the will of the late Andrew J. Dotger, of South Orange, N.J., the Tuskegee Institute will receive 131,000*l.* on the death of his wife. It is also interesting to record that about 10,000*l.* has already been raised for the new professorship of lumbering in the Yale Forest School of the 30,000*l.* which is sought as an endowment. In fourteen western States 8800*l.* was raised from sixty contributors.

Among the courses of lectures to be held during May, arranged for advanced students and others in connection with the University of London, the following may be mentioned. A course of about seven lectures on the morphology of the Bryophyta will be given at the Chelsea Physic Garden by Prof. J. B. Farmer, F.R.S., beginning on May 8; a course of eight lectures on the physiology of nerve will be delivered in the physiological laboratory of the University by Dr. N. H. Alcock, commencing on May 8; and a course of four lectures on the atmospheric circulation and its relation to weather will be given on May 1, 8, 15, and 24 by Dr. W. N. Shaw, F.R.S.

In the Journal of the Royal Sanitary Institute (vol. xxvii., No. 3) Dr. G. Reid gives drawings of a new type of elementary school now adopted by the Education Committee of Staffordshire. The central hall type of building hitherto in favour was found to present difficulties in making adequate provision for ventilation by natural means, and a plan of building was adopted in which one semi-detached hall would serve for three departments, the class-rooms being designed in pavilion form with veranda communication. The cost of erection of the new type is considerably less than that of the central hall type, the cost of schools to accommodate 1020 and 628 children respectively being 10*l.* 10*s.* and 11*l.* 1*s.* in the former case as compared with 15*l.*, which was the average cost per head of the central hall type of building.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 7, 1905.—"On the Inheritance of Coat Colour in Horses." By C. C. **Hurst**. Communicated by W. Bateson, F.R.S.

Analysis of the Stud Book shows that in thoroughbred horses chestnut is a Mendelian recessive to bay and brown, which are dominants. Omitting other colours, it appears that when mated with chestnuts, bays and browns are either (*a*) pure DD, giving no chestnut foals, or (*b*) DR, giving, on an average, equality of chestnuts and of dominants.

Chestnuts mated with chestnuts (of any ancestry) breed true to chestnut, with about 1 per cent. of exceptions (9 in 1104), which may perhaps be due to errors in the records.

These observations differ from those of Prof. Pearson, who found no intrinsic difference between the inheritance of chestnut and other colours (Phil. Trans., A, vol. cxcv.), and has declared (*Biometrika*, ii., p. 214) that Mendelian principles do not apply to horse-colours.

(*Note added January* 31.)

In the paper read January 18 Prof. Weldon disputes these conclusions, while admitting that chestnuts breed true with about 1·5 per cent. of exceptions. His argument depends on the recorded exceptions. The Stud Book is very accurate, but many of the records are afterwards corrected, and there is sufficient margin of demonstrable error to make it possible that the rare exceptions which cannot be eliminated may be due rather to mistake than to physiological peculiarity in the animals. Very few of the supposed exceptions have appeared in public uncorrected. Genuine exceptions may perhaps occur, but the returns have scarcely the extreme precision necessary to establish such occurrences. Similarly the records show occasional exceptions to the purity of the pure dominants—about 1 per cent.

It is no doubt by including the families in which these exceptions occur among those from the DR dominants that Prof. Weldon has found a large excess of dominants from the mating DR × R.

Finally, the distinct properties of chestnuts must be ascribed to segregation and not to ancestry, for their behaviour in heredity is entirely different from that of bays and browns, though their ancestral composition may for several generations have been the same.

January 25.—"Observations and Photographs of Black and Grey Soap Films." By Herbert **Stansfield**. Communicated by Prof. Schuster, F.R.S.

This paper describes some work on soap films that originated with an examination of the two kinds of black films, undertaken in connection with a continuation of Reinold and Rücker's researches on soap films. The two kinds of black soap film were first described by Newton. Reinold and Rücker made electrical measurements which indicated that one black film was twice the thickness of the other, and this result has been confirmed by Johonnott's measurements with a Michelson interferometer. Johonnott found that the limiting thickness of the thicker black was 12 $\mu\mu$ (micromillimetres), after which it changed abruptly to the thinner black, 6 $\mu\mu$ thick.

Vertical plane films were examined by reflected light with a low power magnification, and it was found that the abrupt change from the thicker to the thinner black could readily be observed with films made from a solution of sodium oleate in water. It was also found that the change from one black to the other was the last and most striking of a series of similar changes that take place as a film thins. The process of thinning appears to be continuous and gradual until a thickness of about 100 $\mu\mu$ is reached, but after that it is accompanied by a series of abrupt steps. The photographs, taken with a camera and film box made for the purpose, show the two black films and three stages between the coloured part of the film and the thicker black which are called the first, second, and third greys, the numbers increasing with the thickness as in Newton's orders of colours.

The photograph reproduced in Fig. 1 shows a vertical frame, made of thin glass rod, supporting a film which is in the act of changing from the thicker to the thinner black; the small white discs that are formed on the advancing boundary of the thinner black appear to consist of material removed in the process. A narrow line of the first grey and traces of the thicker greys can still be seen between the coloured part of the film and the black.

A film shut up in an air-tight glass cell containing some of the soap solution does not thin beyond the thicker black stage if the equilibrium between the film and the water vapour is not disturbed. The thinner black is formed if

FIG. 1.—Oleate of soda film. Magnification 9. Photograph showing formation of the thinner black, and remnants of the grey stages.

evaporation takes place from the film; it may be produced by bringing a light near to the cell. Johonnott has recently shown that the same effect can be produced by a sudden increase of pressure in the cell. The change back again from the thinner to the thicker black, or to still thicker stages, can be produced by causing water vapour to condense on the film.

The paper also deals with the formation of the coloured patches which are often seen moving down through a coloured film. They have round heads and drawn out tails, and bear some resemblance to tadpoles. The head often shows concentric rings of colour, indicating that it is like a convex lens in shape. These tadpoles, or lens-

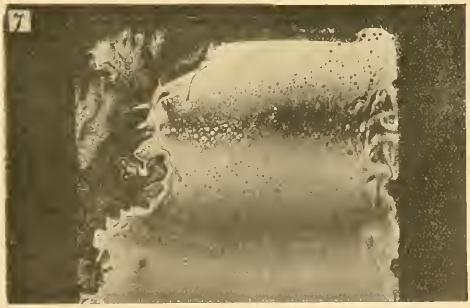

FIG. 2.—Oleate of potash film. Showing a growth of solid material on the left side, and lens-shaped thickenings falling through the coloured part of the film.

shaped bodies, often have their origin in minute grains which form in the black at the top of the film.

Fig. 2 shows the way in which solid material sometimes grows in a film. The film represented, instead of thinning in the usual way and becoming all black, only developed a few millimetres of black at the top, and then continued for hours to produce swarms of lens-shaped thickenings. When a film is behaving in this way, the grains in the

black and the lens-shaped thickenings in the coloured part of the film may be seen shooting into the tips of the dendritic growth of solid material.

The separation of solid matter in a soap film is probably connected with the formation of solid pellicles on the surfaces of aqueous solutions, which has been described by Ramsden, and it supports the theory of churning, advanced by Agnes Pockels, that the butter separates out in the bubbles formed in the churning process.

A film which is thinning rapidly owing to rapid evaporation often develops a curious "grey pattern" when a considerable amount of black has been formed. This pattern sometimes shows five or six grey stages of thickness, and seems to be produced by material spreading out into the film from thickenings which have accumulated during the thinning process.

It is suggested that the grey pattern, the grains in the black, and the lens-shaped thickenings are formed, like the solid growths in the films, by the concentration of the soap solution.

February 15.—"The Influence of Increased Barometric Pressure on Man. No. I." By Leonard **Hill**, F.R.S., and M. **Greenwood**.

The results of the present investigation show that

(1) A man can be submitted to a total pressure of seven atmospheres without untoward effects, provided decompression be effected gradually, and the capillary circulation be aided by repeated contractions of muscles, joint movements, and changes of posture.

(2) There is no sense of increased barometric pressure so long as the former is constant.

It is probable

(1) That the subjective effects of increased pressure, apart from voice changes and lip anæsthesia, depend upon psychical conditions, such as anxiety and excitement.

(2) The changes in the percentage of carbon dioxide in the alveolar air are conditioned solely by physical variations, and not by any increase or diminution in the respiratory metabolism.

In conclusion, the authors remark that they were unable to find any evidence in support of Snell's opinion ("Compressed Air Illness, or so-called Caisson Disease," London, 1896, Lewis, p. 212) that the presence of CO_2 in the respired air exercises a peculiarly unfavourable influence under increased pressure. Thus in one experiment the percentage of CO_2 in the chamber air, at +31lb., was 0·62 (equivalent to more than 1·8 per cent. at +0), and no untoward results occurred on decompression.

Society of Chemical Industry (London Section), April 2.—Mr. A. G. Salamon in the chair.—Ropiness in flour and bread, its detection and prevention: E. J. **Watkins.** Breads most frequently attacked by this disease are such as contain bran or low-grade white flours. In the present investigation it has been sought by means of culture experiments and the artificial production of ropiness in sound flour to establish the identity of an organism isolated from specimens of ropy bread and flour obtained in England. Cultures made from this bread yielded a small motile bacillus which, after repeated subculturing, was used in a series of experiments made with a known sound flour. Varying proportions of the culture were added to the water used for making dough. Such doughs when fermented showed no sign of bacterial effects, and the bread produced was of normal character when it left the oven. The bread when kept in a moist atmosphere at temperatures of 25° C. to 35° C. became ropy in about twenty-four hours. When the temperature was kept below 18° C. the disease did not appear. Dryness of the air generally prevented ropiness even when the temperature was high. Acids exercise a powerful influence in preventing the growth of the bacillus, it being found in a series of tests with varying quantities of acetic acid in the dough that the bread did not become ropy when kept long periods under conditions suitable to the bacillus. The cultural and microscopic characters prove the organism to be *Bacillus mesentericus* (Flügge).—The Röse-Herzfeld and sulphuric acid methods for the determination of the higher alcohols; a criticism: V. H. **Veley.** The two methods generally adopted for the determination of the higher alcohols are the Röse-Herzfeld (officially recognised in this country, Germany, and Switzerland) and the sulphuric acid method, adopted in France, consequently practised in this country, and officially used as a general qualitative test for the purity of all kinds of alcohol in Russia. Since these methods give very divergent results in the hands of different analysts, the author records various experiments to determine the accuracy or otherwise of the processes, and also criticises them.

Entomological Society, April 4.—Mr. C. O. Waterhouse, vice-president, in the chair.—Specimen of the very rare ant *Formicoxenus nitidulus*, a neuter, found in a nest of *Formica rufa* at Weybridge during the present month: H. St. J. **Donisthorpe.**—Specimen of *Platypsylla castoris*, Ritsema, a coleopterous parasite of the beaver, from France: G. C. **Champion.**—Specimens of a Noctua, believed to correspond to Dr. H. Guard-Knagg's original description of *Agrotis helvetina* ("Entomologist's Annual," 1872): W. S. **Sheldon.**—Examples of butterflies taken last year in Majorca showing injury to the wings, caused apparently by the attacks of lizards: A. H. **Jones.**—An account of the calcara observed on the legs of some Hymenoptera: Rev. F. D. **Morice.** The calcara were, the author said, quite constant in each species, and useful, therefore, as distinguishing characters, the only hymenopteron he had come across without them being the ordinary hive-bee. Kirby and Spence considered that they were used for climbing purposes, but this was unlikely, as the spurs occurred in species which did not climb at all. So far as he had noticed, they were used by members of this order for the purpose of cleaning their antennæ. Mr. C. O. Waterhouse said that similar spurs existed in the Trichoptera, though they did not assume beautiful forms as in the Hymenoptera; but as to their uses, he was not aware that any observations had been published or made on the subject. Mr. G. C. Champion remarked that they were also well developed on the hind-legs of some Coleoptera.

Linnean Society, April 5.—Dr. A. Smith Woodward, F.R.S., vice-president, in the chair.—Some plants new to the pre-Glacial flora of Great Britain: Clement **Reid.** Fifty photographs were exhibited derived from material procured at Pakefield, near Lowestoft. The remains were black, and therefore troublesome to photograph, but the specimens themselves could not long be preserved, as an efflorescence occurred, and they fell to pieces, but experiments were now being conducted with the view of permeating the fruits with paraffin, and so ensuring their preservation.—A second contribution to the flora of Africa: Rubiaceæ, and Compositæ part ii.: S. **Moore.** In a former memoir composite plants were alone dealt with. In the present paper are submitted descriptions of Rubiaceæ as well as of Compositæ. To the former natural order twelve new additions are proposed, referable to the following genera:—Otomeria, Oldenlandia, Heinsia, two species of Tarenna, Randia, Tricalysia, Polysphæria, and two species each of Canthium and Diodia. The Compositæ regarded as new number fifteen, of which Helichrysum claims six species; Vernonia, Inula, and Senecio two each, and Felicia, Bidens, and Dicoma one each.—The structure of the stem and leaf of *Nuytsia floribunda*, R. Br.: E. J. **Schwartz.** *Nuytsia floribunda* is a member of the Loranthaceæ and a native of West Australia, and, unlike other members of this order, it is non-parasitical and a tree attaining a height of some 30 feet.—Taiwanites, a new genus of Coniferæ from the Island of Formosa: B. **Hayata.** Dr. Masters considers the genus a valid one, judging from a small scrap which he had received from the author, who believed his new genus to be intermediate between Cryptomeria and Cunninghamia; he himself pointed out that it combined the foliage of Athrotaxis with the cone of Tsuga; in any case it is a very interesting genus.

Royal Astronomical Society, April 11.—Mr. W. H. Maw, president, in the chair.—Explanation of the apparent secular acceleration of the earth's orbital motion: P. H. **Cowell.** The author had found that certain arbitrary assumptions with regard to the sun and moon satisfied the conditions of six ancient solar eclipses. He concluded that it was wrong to assign an arbitrary secular acceleration to the moon and none to the sun, and to justify this by

supposed tidal influence. The rate at which the day increases appears to be 0.005s. per century, this being about ten times greater than previous estimates.—Planetary inversion: F. J. M. **Stratton.** The author had been led to this investigation by Prof. Pickering's suggested explanation of the cause of the retrograde motion of Phœbe, the ninth satellite of Saturn. It was assumed that at the time this satellite was thrown off from its primary the latter had a retrograde motion of rotation, which subsequently became changed to a direct motion by the inversion of the planet's axis. The author concluded that while the theory remains for the present a speculative hypothesis, it is supported by the theory of tidal friction, and gives the only explanation of certain facts that has so far been put forward.—High-level chromospheric lines and their behaviour in sun-spot spectra: Prof. A. **Fowler.** The observations showed that enhanced lines appear as high-level lines in the chromosphere, and that the corresponding Fraunhofer lines are generally enfeebled in the spectra of sun-spots.—Discussion of the Harvard observations of the eclipses of Jupiter's satellites, 1878–1901: Prof. R. A. **Sampson.** The author gave an account of this discussion, which will be published by the Harvard Observatory.

CAMBRIDGE.

Philosophical Society, March 12.—Dr. Fenton, vice-president, in the chair.—A theory of the widening of lines in the spectrum: Prof. J. J. **Thomson.** The view put forward is that the widening of the lines is due to resonance. The luminous molecules emit waves of light, and as these are also waves of electric and magnetic force, a luminous particle produces a strong electrical field in its neighbourhood; this will act on the vibrating electrified particles in a neighbouring luminous molecule, while this second molecule will exert similar forces on the first molecule. Two adjacent luminous particles thus exert forces on each other, and, if the natural periods of the two are equal, the action between them may result in a considerable change in the period. As the vibrating systems are surrounded by many systems, some at one distance and others at another, the changes produced in the periods will not be constant, but may have any value included between certain limits, the range between the limits increasing with the number of luminous molecules. This range in the value of the periods causes the original bright line to be spread out into a band.—The transmission and reflection of the radiation from radio-active substances: Prof. J. J. **Thomson.** The amounts of secondary, tertiary, and radiation of a higher order transmitted through and reflected from a plate of matter placed in the path of radiation from radio-active substances are calculated, and methods obtained for comparing the total ionisation produced by the secondary and other rays with that produced by the primary rays.—(1) The asymptotic expansion of the integral functions

$$\sum_{n=0}^{\infty} \frac{x^n \Gamma(1+an)}{\Gamma(1+n)} \text{ and } \sum_{n=0}^{\infty} \frac{x^n \Gamma(1+n\theta)}{\Gamma(1+n+n\theta)}.$$

(2) The asymptotic expansion of integral functions defined by generalised hypergeometric series: Rev. E. W. **Barnes.**—A method of following the course of certain chemical actions, and a period of induction in the action of water on monochloracetic acid: P. V. **Bevan.** The method described was to determine the resistance of the solution in which the chemical action was taking place. In dilute solutions, when an acid such as hydrochloric acid is set free as the action progresses, this method affords a very delicate way of observing the rate of decomposition. The action of water on monochloracetic acid was investigated, and was found, except just at the beginning, to follow the normal monomolecular course.—The radio-activity of metals and their salts: N. R. **Campbell.** Measurements of the activity of metals and their salts show that the radio-activity of ordinary materials is an atomic property. The identity in respect of this property of samples of the same salt prepared by different methods shows that the apparent activity cannot be due to impurity.—A relation between the velocity and the volume of the ions of certain organic acids and bases: T. H. **Laby** and G. A. **Carse.** A method of finding the relation between the velocity and linear dimensions of an ion is to calculate the latter by taking the cube root of the ionic volume found from the molecular and atomic volumes, and combine this with the ionic velocity. It is found that the product of these two quantities is approximately constant for the members of the homologous series which the authors have examined, viz. the fatty acids, amines, pyridines, and anilines, but varies from series to series.—A preliminary note on the maiotic phenomena in the eggs of the hermaphrodite *Angiostomum nigrovenosum* (*Ascaris nigrovenosa*): S. A. **McDowall.** The synapsis of the chromosomes is very clearly shown in this animal.—The reduction of the general ternary quintic to Hibbert's canonical form: H. W. **Richmond.**

DUBLIN.

Royal Dublin Society, February 20.—Dr. W. E. Adeney in the chair.—The vapour pressure of a pure liquid at constant temperature: Prof. Sydney **Young.** In order to find whether the statement contested by Battelli and others, that the vapour pressure of a pure liquid is independent of the relative volumes of liquid and vapour, is borne out by experimental observations, the author has collected together the results of his determinations of the vapour pressures of twenty-seven carefully purified liquids. He points out (1) that errors due (*a*) to the presence of dissolved air and other impurities, (*b*) to the vaporisation of mercury, and (*c*) to readings being taken too rapidly, would have the effect of making the observed pressures higher at small than at large volumes; (2) that those errors must be smaller when readings are taken during evaporation than during condensation; (3) that the errors are likely to be greater at high temperatures than at low ones. With twenty-one out of the twenty-seven pure substances, forty-five series of determinations were successfully carried out, the liquids having been almost free from air, and no signs of decomposition having been observed. There were 493 determinations of vapour pressure, each being the mean of, as a rule, four readings taken at different volumes. That the mean observed fall in pressure during evaporation for the 257 determinations at temperatures up to 180° was less than 1 in 10,000 may be regarded as a proof that the vapour pressure is really independent of the volume. At temperatures above 180° the mean fall in pressure for 236 determinations was 1 in 1450.—Views illustrating the permo-Carboniferous glaciation of South Africa: Prof. G. A. J. **Cole.**

March 20.—Prof. Sydney Young, F.R.S., in the chair.—Electromagnetic mass: Prof. A. W. **Conway.** This was a continuation, in an expanded form, of the paper read at the meeting held January 16.

PARIS.

Academy of Sciences, April 9.—M. H. Poincaré in the chair.—Some problems in mathematical physics appertaining to the equation of M. Fredholm: Émile **Picard.**—A means of controlling a system of clocks synchronised electrically: G. **Bigourdan.** In a system of clocks controlled electrically the synchronism may be disturbed owing to various causes. By the use of a galvanometer attached to each controlled clock, and the suppression of the directing current once in each minute, at the zero second, any deviation can be measured.—Concerning the presentation of a number of the "Catalogue photographique du Ciel" from the Observatory of Toulouse: M. **Lœwy.** This number is chiefly devoted to the measurements of the rectilinear coordinates of stellar images taken photographically with a view to the determination of the solar parallax by means of the planet Eros.—The transformations of systems of partial differential equations of the second order: J. **Clairin.**—The dichroism, double refraction, and conductivity of thin metal plates obtained by kathode pulverisation: Ch. **Maurain.** The effects described were shown most strongly by bismuth, but similar results were obtained with gold and nickel.—Gaseous osmosis through a colloidal membrane: Jules **Amar.** From the experiments described the author concludes that gaseous osmosis through the tissue employed is in accord neither with the experimental laws of Bunsen and Graham nor with the theories of Stefan and O. Meyer.—The variations of the absorption bands of a crystal in a magnetic field: Jean **Becquerel.** Some of

the results obtained can be most readily explained by assuming that certain bands correspond to the vibrations of positive ions.—The production of high vacua by means of liquid air: Georges **Claude** and René J. **Lévy**. The arrangement is based on the absorption of gases by charcoal at the temperature of liquid air.—The acoustic properties of certain halls for speaking: M. **Marage**. Experiments confirming the views put forward on the resonance of halls by Wallace Sabine.—The variations of some properties of quartz: H. **Buisson**. Two fine specimens of quartz were compared, measurements being made of their density, coefficient of expansion, double refraction, refractive index, and rotatory power. There were distinct differences between the two specimens, all the deviations being in the same sense. It is thus clear that quartz, even well crystallised, cannot be considered as a perfectly pure substance with absolutely defined properties, or even as a homogeneous body.—The radio-activity of springs of drinking water: F. **Dienert**.—Some pyrophosphoric compounds: J. **Cavalier**. The preparation and properties of the pyrophosphoric esters of ethyl, propyl, butyl, and amyl alcohols are described. They all proved to have molecular weights corresponding to the formula $R_4P_2O_7$, determined by the cryoscopic method.—Barium iodomercurates: A. **Duboin**.—The pure ferromolybdenums: Em. **Vigouroux**. In the direct combination of iron and molybdenum with the iron in excess, the definite compound Fe_2Mo is formed, and no other compound containing less molybdenum appears to be capable of existence.—The influence of the ketonic and acid grouping in the same molecule: L. J. **Simon**.—The condensation of the acetylenic amides with phenols. A general method for the synthesis of ethylene-oxyphenol amides: Ch. **Moureu** and J. **Lazennec**.—The genesis of an iron mineral: L. **Cayeux**.—A preliminary note on globoids and certain granulations of seeds, resembling the metachromatic corpuscles in some of their properties: J. **Beauverie** and A. **Guilliermond**.—The Khaya of Madagascar: H. **Jumelle** and H. Perrier **de la Bathie**. Reasons are shown for regarding this as a new species, *Khaya madagascariensis*.—Study of the variations of nitrogen and phosphoric acid in the juices of a grass plant: G. **André**.—The treatment of seed with copper salts: E. **Bréal**. The superficial sterilisation of seeds by copper solutions not only prevents cryptogamic diseases, but also causes a good utilisation of the reserves.—The heats of combustion and the composition of the bones of the skeleton of the guinea-pig, considered as a function of the age: J. **Tribot**.—The nucleus of the red blood corpuscles in birds: M. **Piettre** and A. **Vila**.—The Pleistocene glaciers in the valleys of Andorra and the neighbouring high Spanish valleys: Marcel **Chevalier**.—Contribution to the Tertiary flora of northern Morocco: Ed. **Bonnet**. Observations on moving shadows at sunset and sunrise: Cl. **Rozet**. The phenomenon of moving shadows has hitherto been observed only during an eclipse of the sun. The author points out the conditions under which the same phenomenon can be seen at sunset and sunrise.—Measurements of the variations of the gravitation constant in the Simplon Tunnel: Marcel **Brillouin**. The results of atmospheric studies in the region of the trade winds: L. **Rotch** and L. Teisserenc **de Bort**.

CAPE TOWN.

South African Philosophical Society, February 28.—Dr. J. C. Beattie, president, in the chair.—Rock specimens showing the occurrence of Glacial beds in the Griqua Town series of Hay: A. W. **Rogers**. Flattened and striated stones, the peculiarities of which can at present only be attributed to glacial agencies, occur in a hard ferruginous rock near the top of the Griqua Town series in Hay. They are of various sizes, from an inch or two up to 18 inches long. They consist of chert; a few grit pebbles are found, but as yet no granites or other igneous rocks are known from those beds; some hollows, now partly filled with specular iron, may represent limestone fragments. The boulders are scattered at wide intervals through the matrix in most cases, though gravelly grits also occur.—Under water in south-eastern Bechuanaland: A. L. **Du Toit**. The term south-eastern Bechuanaland is used as including the divisions of Mafeking and Vryburg as far westwards as Kuruman.—A set of linear equations connected with homofocal surfaces: Dr. Thos. **Muir**.

DIARY OF SOCIETIES.

MONDAY, APRIL 23.

SOCIETY OF ARTS, at 8.—Ivory: Alfred Maskell.

VICTORIA INSTITUTE, at 4.30.—Review of Sir Henry H. Howorth's "Ice or Water": Prof. Edward Hull, F.R.S.

WEDNESDAY, APRIL 25.

GEOLOGICAL SOCIETY, at 8.—Trilobites from Bolivia, collected by Dr. J. W. Evans in 1901–1902: Philip Lake.—Graptolites from Bolivia, collected by Dr. J. W. Evans in 1901–1902: Dr. E. M. R. Wood.—The Phosphatic Chalks of Winterbourne and Boxford (Berkshire): H. J. Osborne White and Llewellyn Treacher.

THURSDAY, APRIL 26.

ROYAL INSTITUTION, at 5.—The Digestive Tract in Birds and Mammals: Dr. P. Chalmers Mitchell.

SOCIETY OF ARTS, at 4.30.—Seistan, Past and Present: Colonel A. H. McMahon.

THURSDAY, APRIL 26, 1906.

THE NEW ORGANIC CHEMISTRY.

Chemie der alicyklischen Verbindungen. By Prof. Ossian Aschan. Pp. xlv + 1163. (Brunswick: Vieweg und Sohn, 1905.) Price 40 marks.

FEW reflections are more curious than those which contrast the manifold complexity of the organic chemistry of the present day with the crude simplicity of the fundamental conceptions upon which it has been built up. Broadly speaking, these conceptions are but two in number—first, the almost repulsively mechanical atomic theory of Dalton, which we still retain in practically its original form, and second, the irritatingly mysterious doctrine of valency introduced by Frankland and Kekulé, also still preserved much as it was enunciated, but which eludes our grasp and sets us chasing shadows so soon as we attempt to translate it into definite mechanical conceptions. Yet, on the ground-work afforded by these two conceptions, so irreconcilable in their nature and so hopelessly crude in the eyes of the physicist, the organic chemist has built up a purely experimental science which embraces hundreds of thousands of different substances within a scheme as perfect as any known to science, which classifies with similar perfection the reactions by means of which those substances are produced and the behaviour which they exhibit, and has led to the synthetic preparation of hosts of compounds the production of which our immediate predecessors regarded as amongst the most intimate secrets of animal and vegetable life.

This result has been attained by the systematic development of experimental methods, and by applying those methods, as they became sufficiently powerful, to the consecutive study of the diverse classes of compounds occurring in organic chemistry. Long ago, experimental methods were sufficiently strong to permit of their successful application to large numbers of aromatic compounds. To-day, the rough methods of the older chemists have become largely superseded by far more delicate ones, by methods which render possible the building up, piece by piece, of the fragile molecular structures numbered amongst the alicyclic compounds. The organic chemist has probably always realised the filamentary character of his hypotheses, and, knowing that he has no prophetic or far-reaching mathematical theory with which to eke out his own cunning, has been led to rely very largely upon his own manipulative skill. For this reason, and more especially is this the case in the branch of the subject now under consideration, organic chemistry partakes of the nature of an art as much as of that of a science, and to be successful, the organic chemist must be endowed with a sort of intuition which education cannot impart and instruction cannot destroy.

The systematic study of the alicyclic compounds dates back only some twenty-five years. At that time the wonderful successes achieved amongst the aromatic compounds by Kekulé and his followers seem almost to have suggested that all complex organic substances might be benzene derivatives. One of the most important alicyclic compounds known to us, namely, camphor, was formulated by Kekulé as an aromatic substance, and for long the Kekulé constitution for camphor held its own, in spite of objections raised by Armstrong and others. Gradually, however, as the early work of Freund, and especially of W. H. Perkin, jun., was developed, it became clear that benzene derivatives are not the only possible closed chain carbon complexes, and derivatives of 3, 4, 5, and 6 membered closed carbon chains were prepared synthetically; it was thus demonstrated that there exist in nature many important closed ring compounds which belong to a class totally different from that of the aromatic compounds, and which may be termed, as Bamberger first suggested, the alicyclic compounds.

A work like the present, which aims at giving a full and complete account of all that has been done in a subject which has grown so rapidly, and is even yet but in its childhood, is greatly needed, and probably no one is better equipped for successfully carrying out the colossal task involved in its production than Prof. Aschan, of Helsingfors. For the worker in this subject, such a book as Aschan has produced is invaluable, if only as an aid to the mnemonic arrangement of his knowledge, and for the student, face to face with the task of studying hundreds of lengthy memoirs, such a classified digest of the whole subject as is here provided offers invaluable indications as to what must be read and what may be safely disregarded.

The classification adopted in the work consists primarily of a division into a general and a special part; further, each division of the subject is ushered in by an historical introduction, which is both interesting and of considerable educational value as leading up, tersely and plainly, to the main theme. The general part includes an introductory chapter defining the scope of the subject dealt with, a theoretical discussion relating to the development of the subject, a discussion as to the influence of ring formation upon the chemical and physical properties of ring compounds, and an exposition of the stereochemistry of alicyclic substances. The special part comprises a systematic description of the methods of formation and preparation of alicyclic compounds, followed by a detailed and equally systematic presentation of our present knowledge of monocyclic, bicyclic, tricyclic, and polycyclic carbon compounds.

The variety of types and the complexity of detail involved in the study of the alicyclic compounds possibly make essential the primary division of the work into a general and a special part; the instances which can be quoted in which some repetition results from the introduction of a general summary as a preliminary to the detailed section are therefore, perhaps, unavoidable in a work of this kind. At the same time, any duplication of matter in the general summary and the detailed description has some drawbacks, because it increases the actual number of pages to be got through without essentially affecting the

amount of information which is imparted: and the stream of literature incessantly poured upon the unfortunate chemist is now so voluminous that few can attempt to read even the most interesting work in detail; the pages have to be merely skimmed through, and the task of forming and storing an adequate visualisation of the whole is possible only to the highly trained memory.

The general arrangement of the book, although highly systematic, sometimes leads to difficulties in finding any desired subject. Thus, the dihydrophthalic acids are dealt with on p. 827, the tetrahydrophthalic acids on p. 771, and the hexahydrophthalic acids on p. 702; yet all these substances were prepared by v. Baeyer at the same time and described in the same paper. The difficulty of finding one's way about the book would, however, be far greater were it not for the excellent index and detailed table of contents.

In the sections devoted to the terpenes and the camphor group, we cannot but miss the spirit of selection and criticism which lends such fascination to the account of the same branch of organic chemistry given by Prof. Harries in Meyer and Jacobson's "Handbuch der organischen Chemie." But, after all, Aschan's book is so replete with valuable detail that any serious attempt on his part to exercise the critical faculty might have impaired the usefulness of the whole work. At the same time, the value o the book as a comprehensive digest would certainly be the greater if more stress had always been laid on investigations which really mark an epoch. Thus, the brief mention made on pp. 501 and 563 of Perkin and Thorpe's recent synthesis of α-campholytic and isolauronolic acids appears quite inadequate in view of the way in which this synthesis cleared the field and settled definitely the question of the constitutions of these two important acids.

A similar objection may be raised in connection with the otherwise excellent discussion of the constitution of pinene on pp. 170 to 186, from which it is by no means easy for the casual reader to discern the really essential points in the complicated argument. The whole discussion relating to this problem centred for a long time upon the constitution of isocamphoronic acid, and for this Tiemann and Semmler offered the formula

$$HO.OC.CMe_2.CH(CH_2.CO.OH)_2,$$

whilst v. Baeyer suggested

$$\begin{array}{l} \quad\;\; CMe_2.CH_2.CO.OH \\ \qquad\;\; | \\ HO.OC.CH.CH_2.CO.OH \end{array}.$$

The discussion was settled once and for all by Perkin, who prepared both these acids and proved thereby that the Tiemann and Semmler constitution correctly represents isocamphoronic acid. No mention seems, however, to be made in the work of these two syntheses, although they are vital to the argument.

In such a comprehensive work as the one under consideration it is surprising that so few slips and omissions occur. On p. 22, lines 13 to 32, and p. 23, lines 10 to 37, the action of sodioacetacetic ester upon trimethylene bromide is stated, in accordance with the original paper of 1883, as leading to the formation of acetyltetramethylenecarboxylic ester,

$$CH_2\begin{array}{c} \diagup CH_2 \diagdown \\ \diagdown CH_2 \diagup \end{array}C\begin{array}{l} \diagup COMe \\ \diagdown CO.OEt \end{array},$$

but no mention is made of Perkin's subsequent demonstration that this reaction, both in the case of acetacetic and of benzylacetic ester, really leads to the production of oxygenated ring compounds, thus:—

$$\begin{array}{l} CH_2{-}CH_2{-}C.CO.OEt \\ | \qquad\qquad\quad \| \\ CH_2{-}{-}O{-}{-}CMe \end{array} \quad \text{and} \quad \begin{array}{l} CH_2{-}CH_2{-}C.CO.OEt \\ | \qquad\qquad\quad \| \\ CH_2{-}{-}O{-}{-}CPh \end{array}$$

although when sodiomalonic ester is employed a tetramethylene derivative actually results. The reaction is correctly stated in the special part of the work at p. 418.

Further, on p. 38, v. Baeyer's old condensation of three molecules of malonic ester into one of phloroglucintricarboxylic ester is still figured in all that simple symmetry which constitutes one of the glories of our elementary text-books. No mention is made of Moore's proof (*Trans. Chem. Soc.*, 1904, 165) that the product is really the phloroglucindicarboxylic ester of Bally, although v. Baeyer himself refers to the correction in his recently published collected works.

A curious slip occurs on p. 585 probably as the result of confusion with the work of Zelinsky—where Perkin and Haworth are represented as having prepared hexamethylene by the action of sodium on *bromocyclohexane* in boiling *alcoholic* solution, but where an equation is given representing the action of sodium on hexamethylene bromide. The synthesis was actually effected by the action of sodium on hexamethylene bromide in metaxylene solution; the action of sodium in boiling alcoholic solution would obviously have led to the production of normal hexane.

A valuable section is devoted to the discussion of the stereochemical relationships which may exist between isomeric alicyclic compounds, and the elucidation of the isomerism is materially facilitated by the use of carefully designed figures; the somewhat intricate stereochemistry of these substances can hardly be brought home to the reader more clearly than is here done. On p. 354 an erroneous constitution is assigned to isolauronic acid, and the deduction drawn therefrom that this acid can exist in four optically active modifications; isolauronic acid actually contains no asymmetric carbon atom, and, as is clear from the correct constitution assigned to it on p. 698, is incapable of exhibiting optical activity.

The section dealing with irone, ionone, and allied substances possessing the odour of violets forms a particularly lucid exposition of the finest piece of work done by Tiemann. Amongst the copious references given is to be noted one of the first fruits of the system of abstracting chemical patents introduced into the *Chemisches Centralblatt* during the last few years. Now that so much of the pioneer work in organic chemistry appears for the first time in patent specifications, references to the patent literature are

as necessary as references to the ordinary scientific journals.

In reading chemical compilations of German origin we are sometimes struck by the scant attention received by work done in this country, and are often forced thereby to the conclusion that the author's study of English chemistry is limited to the system of abstracts issued by the Berlin Chemical Society. No such fault can be found here; the author is obviously as much at home in the Journal of the Chemical Society as in the Continental journals, and gives full credit to all results, from whatever source they are derived.

For Aschan's new book, as a whole, nothing but praise is possible, and the few points to which objections have been made rank as nothing when regarded as raised from the perusal of a book 1200 pages long, which aims at giving a systematic account of the alicyclic compounds. The study of these substances has been mainly carried out at fever heat during the past quarter of a century, and the necessarily ragged way in which the results have been laid before the world in the current journals must have offered immense difficulties to the compiler.

We cannot close this book, containing as it does a lucid account of one of the most important and intricate sections of organic chemistry, without reflecting with pleasure that the intense but systematic work which has led, during the last twenty years, to the synthetic building up of such complex molecular structures as those of camphor and of the terpenes has been largely carried out in our own country.

W. J. P.

THE SYSTEM OF THE FIXED STARS.

Der Bau des Fixsternsystems mit besonderer Berücksichtigung der photometrischen Resultate. By Prof. Hermann Kobold. Pp. xi+256. (Brunswick: Vieweg und Sohn, 1906.) Price 5.60 marks.

To prove that the stars form a stable system is a problem that has had attractions for many philosophical minds. The problem has not been solved, possibly may not be capable of solution, but the attractiveness of the speculation remains. Analogy with the solar system has suggested, and given support to, such an idea. The harmony that is to be perceived in the ordered motions of the planets, permitting countless revolutions to be performed without permanent change or irregularity, might well give rise to the hope that the same principle that governs the solar system could be detected in the larger scheme of the stellar universe. Such an idea would naturally have sway at a time when speculation was little fettered by numerical data drawn from rigorous observation. If there was little evidence to support the notion, there was nothing to contradict it. Kant or Lambert could suggest without difficulty that the stability of the system was secured by each star moving in a definite orbit, which ensured the maintenance of the general form and arrangement. The influence that that thought has exercised on modern investigation is of more importance than the thought itself. To suspect the influence of the Milky Way in the scheme of the Cosmos, and to make its investigation the centre of inquiry, was to bequeath us a legacy which is by no means exhausted. Later schemes suggested by improved instrumental appliances have widened the scope and raised fresh issues, but the significance of the Milky Way remains. Similarly with the problem of the sun's motion, which a hundred years ago Herschel solved so satisfactorily, considering the character of his material. Disputed by Bessel and supported by Argelander and a host of later astronomers, the solution has passed through many stages and given rise to novel methods of treatment, involving the application of fresh hypotheses. In these later times we have pressed into the service the results brought to light by the spectroscope, especially difficult of interpretation as they are, and allowing the exercise of much ingenuity. But the essential problem remains the same. The only question is, What advances have we made in solving the riddle which perplexed earlier investigators?

In proportion as the problem becomes more and more complicated, either by repetition of similar processes or the introduction of fresh ones, the greater is the necessity for the examination of the evidence to test its value in combination, and of bringing the whole material to bear in one consecutive argument. This is the task which Dr. Kobold has undertaken, and in which he has acquitted himself with credit. One may not in every case draw the same conclusion, or with the same certainty, that the author does, but the evidence is at least presented with completeness, and we have the opportunity of bringing our critical faculty to bear upon the various lines of argument which are marshalled in review. Such a book is instructive to the tyro and suggestive to the expert. The one may adopt the conclusions which the author has drawn up, as indicating the general position of science towards this problem, the other may see the necessity for pursuing fresh lines of research, or of supporting alternative explanations of the results presented. In any case it is an advantage to see what has been attempted and what has been accomplished.

The author divides his book into three sections. In the first he describes on broad lines how the facts which may aid in solving the problem of the construction of the universe have been collected. The reader who comes fresh to this subject, without any previous acquaintance, gains an intelligent notion of the manner in which the positions of the stars have been ascertained, and can grasp clearly the supreme importance of an accurate determination of the precession constant when the question of proper motion is considered. The brilliancy and the colour of stars are both discussed, though the practical bearing of the latter point on this particular problem is not very clear, and in any case is more conveniently dealt with in discussing the spectroscopic observations, which are also brought under notice. Parallax and stellar distribution are adequately described, and therefore in this section we get a tolerably complete sketch of the main processes of stellar observation, except in-

the department of double and variable stars. Into the significance of variable, and especially of "new stars," the author does not enter. Doubtless he is well advised in considering the introduction of such topics premature, but the omission shows that we have a certain class of facts which cannot yet be brought into line with other data. We have not yet succeeded in weaving our information into a consistent whole.

In the second section we have the results of observation mainly as exemplified in the production of star catalogues, whether of place or of spectrum, of brilliancy or of distance, for in these catalogues, applying, as they do, to large areas in the sky, must be contained the information which is to solve the problem of the universe. No inconsiderable portion of this section is occupied with the question of proper motion and the proper method of its treatment. Here we have raised for us, in an acute form, the question of the parallactic as distinguished from the actual motion of the star, and the legitimacy of the assumption as to the absolute lawlessness of direction of the star's own motion. On this and similar points a certain amount of controversy exists, and Dr. Kobold is known to hold very definite views. Fortunately we do not consider it necessary to enter into any of these differences of opinion. We are simply concerned in pointing out the general direction to which the combined information points, and its bearing upon the existence of a stellar system. These conclusions Dr. Kobold collects in his third section, and, greatly daring, has summarised "on half a sheet of notepaper." This statement is so succinctly expressed that it may be reproduced almost literally. Throughout a finite space of spherical form are scattered bodies very different in mass and in physical conditions. With gaseous nebulæ at very low temperature occur other bodies in a condition of glowing heat and advanced condensation. The arrangement of the separate masses is not uniform; they are crowded together in clusters about certain centres of concentration. These groups possess a loose relationship, and are arranged in the form of a spiral having many branches. In the more distant parts of this spiral the hotter and gaseous stars predominate. The sun is comparatively near to the centre of this spiral, and the stars which stand in closest connection with it have also similar physical conditions. On the sun is impressed a motion towards a point in the Milky Way, the principal plane of the whole spiral, and a great number of stars near the sun participate in this same motion. Among the stars there are numerous groups having an apparent motion directed to points in the Milky Way. The stars of each group are in one plane, and their true motion, on the character of which definite information is still wanting, takes place in this plane.

This may seem a very small outcome for so much work, but it will hardly be urged that the author has erred on the side of caution. In any case this "Schlusswort" is valuable, since it expresses the opinion of one who is especially qualified to speak on a subject which possesses in an equal measure both interest and difficulty. W. E. P.

A PHYSIOLOGICAL STUDY OF THE BRITISH FLORA.

British Flowering Plants. By the Right Hon. Lord Avebury. Pp. xxiii+450. (London: Macmillan and Co., Ltd., 1905.) Price 15*s.* net.

LORD AVEBURY has given us in the past several delightful books on botanical subjects, dealing more especially with the forms and functions of leaves, flowers, and fruits. At the time when the earlier of these books were published there was a tendency to reduce botanical morphology to a cut-and-dried series of shapes and forms, each designated by a Latin name the correctness of which received more attention than the purpose served by the various modifications. In "Flowers, Fruits, and Leaves," and "British Wild Flowers in Relation to Insects," Sir John Lubbock adopted the more natural treatment of studying form in the light of function, with the result that on account of their broad conceptions and the appeal they made to the reasoning faculty, these books obtained a wide circulation, and even now they maintain their position among the foremost contributions to the subject. In the circumstances the author has drawn freely from his previous works in writing this volume, which is restricted to British plants, and contains shorter or longer references to all our flowering plants. It provides, therefore, a running commentary to British floras in general and to Bentham's "British Flora" in particular.

On the details of buds and stipules, a subject that Lord Avebury has studied very carefully, much information is provided. In the genus Lathyrus the shape of the stipules varies from the large foliaceous type of *Lathyrus maritimus* through the narrow sagittate stipules of *Lathyrus pratensis* to the minute, slender stipules that occur in *Lathyrus nissolia.* These and other forms found in the genus are collated, and it is pointed out how the shape fits in with the attachment of the leaf to the stem. The complex nature of the stipules of the hawthorn also receives elucidation. A full account is given of the winter buds of the beech, the pine, and the spruce. It will be seen from these that the examination and dissection of the winter buds of trees and shrubs provide a capital exercise for a nature-study class. Considerable attention has been paid to the dichogamous and diclinous conditions of flowers. The ordinary strawberry furnishes a good instance. Darwin distinguished female flowers producing plenty of fruit, complete flowers less fertile, and male flowers naturally bearing no fruit. Schulz observed for the same plant gynomonœcious, andromonœcious, gynodiœcious, and androdiœcious forms. This is only one of several types of variation in the flower that too frequently pass unnoticed. A certain amount of work has been published on floral variation, more recently by students of biometric problems, but there is plenty of opportunity for observations continued over a series of generations to obtain more definite conclusions on the subject of small variations.

An introductory chapter deals with categories and types, as for instance, flowers of water plants,

methods of protection of the flower against rain, &c. The table on p. 18 collating the modes of dispersal of the fruits of our trees and shrubs brings out the facts very distinctly, and similar tabulations will readily suggest themselves. With regard to the individual descriptions, it seems a pity that many are so short and that the vegetative parts have not received more consideration, but obviously in the limits of a single volume this could not be managed. The absence of technical terms, except for the few that are defined in the glossary, renders the book available to all interested in botany. The book is confined mainly to elementary topics, but students of advanced botany will find that they also can learn much from the information supplied, and can obtain not a few references to questions awaiting explanation or requiring more evidence to verify the explanations that have been offered. The illustrations are numerous, well produced, and appropriate.

OUR BOOK SHELF.

Rowing and Track Athletics. Pp. ix+449. The American Sportsman's Library. Edited by Caspar Whitney. Rowing, by Samuel Crowther. Track Athletics, by Arthur Ruhl. (London: Macmillan and Co., Ltd.; New York: The Macmillan Co., 1905.) Price 8*s*. 6*d*. net.

IN this book the history and progress of rowing and track athletics in America are described in a very interesting manner. From the British sportsman's point of view the book will be read with very great pleasure, for it shows how eagerly the Americans have strived, and not in vain, to excel the prowess of the athletes this side of the Atlantic. From the scientific point of view this history is also of value, for it shows the evolution of ideas which have culminated in the present methods.

The old order changeth for the new, and a race cannot now be won as in the old days, when it was customary "to have your friends out in boats on the course and to impede the other crew as much as possible; the race was not always to the swift—if the home man happened to be the slower," as the author here narrates.

At the present day the successful oarsman or track athlete is he who is able to combine with the greatest efficiency a number of variables. In the case of the former, some of these variables include personal fitness, easiness of style, length of oar and width of blade to suit his particular capability, length and weight of boat, and alertness of brain to take advantage of prevailing conditions and possibly unforeseen eventualities.

In this book we see how hard the struggle has been in America to acquire efficiency, and possibly the reason why. In many national characteristics climate plays a very important part, and, in the case of rowing or track athletics, the influence of climate can be clearly detected. The British style of rowing, for instance, has been evolved by Britishers under British weather conditions. The lines on which this efficiency has been secured need not, and should not necessarily, be identical with those evolved in America, since the climate of the latter country is so different from that of the British Isles.

In track athletics the same principle holds, and this is borne out by the fact that, on the average, the American is the fastest sprinter, while the Britisher is best at long distances. In fact, as the author states, "There is, undoubtedly, something magnetic in our American air, at least in the sort of atmosphere that is found in the north-eastern Atlantic States. . . . What the English climate lacks in this stimulating effect it seems to make up in its general soothing and nourishing influence, and if the athlete who has been bred in it is deficient in snap and nervous spring he is strong in endurance and vitality."

Without going into further detail, the reader must be left to read the book for himself. The illustrations, though not very numerous, are typical, and a capital index concludes the volume.

Économie Forestière. By G. Huffel. Tome Premier. Pp. ix+422. (Paris: Lucien Laveur, 1904.) Price 10 francs.

FRANCE has always taken a leading part in sylvicultural science, and the above volume is a good indication of the thorough manner in which this nationally important subject is practised in that country. The French Government has learned by past experience the disastrous results which the injudicious destruction of the forest inevitably brings, but at the same time France can furnish unrivalled examples of the benefits of proper forest management and administration.

The present work is divided into four parts. The first part deals with the use of the forest, both as regards the production of materials applicable to the needs of man and the beneficial influence it has upon the climate. A very interesting historical summary is given of the uses to which the forest was formerly put. This was pretty much the same in all countries, viz. the chase and pasturage. Then came the time when the forest was principally of value in regard to its wood production, especially in France, for firewood, until this was to some extent superseded by coal and other substitutes. A most interesting table is included giving the variations in the price of timber during the nineteenth century in France and Austria. The author also goes into the numerous uses to which timber may be put, and the different substances which are to be got from it by chemical means, from the crude products of distillation to the finest silk. The author further gives a survey of the colonial forests and their products. Then follow two or three chapters dealing with the very important but formerly too frequently disregarded aspect of sylviculture, namely, the influence of the forest on the climate. Very interesting statistics regarding the daily, monthly, and yearly variations of temperature inside and adjacent to the forest are given. Further, the forest influences the humidity of the air. It increases the rainfall. It regulates and preserves the soil-moisture and controls the "flow off" in such a way that disastrous floods and equally pernicious droughts are prevented. The protection forest, and the necessity for its preservation in the high collecting ground, is dealt with in a masterly manner. The forest regions of France, the hygienic influence and æsthetic aspects of the forest, each receives its due share of attention.

In parts ii. and iii. we have a historical account of the forests of France from the very earliest time. Forest administration in all its branches, together with the equipment and training for the State forest service, are fully treated. Part iv., which concludes this volume, contains a vast amount of statistics concerning the present forests and forest regions of France.

The author has evidently spared no pains to make this volume as complete as possible in every way, and it cannot fail to be of great service to those for whom it is written.

Physiologie des Menschen. By Dr. L. Luciani. German Edition by Dr. S. Baglioni and Dr. H. Winterstein. Part v. Pp. 161–320. (Jena: G. Fischer.) Price 4 marks.

THE fifth part of Dr. Luciani's text-book of physiology deals with the mechanical and chemical phenomena of digestion in the alimentary canal, with the absorption and storage of the food-stuffs, and with the excretory functions of the intestinal tract.

The first chapter gives an excellent account of the gastric movements, and of the nerve mechanism controlling them. The second chapter deals with the digestion of the various food materials by means of the pancreatic and intestinal juices, and of the bile. An exceptionally full *résumé* is given of the results following upon removal of extensive portions of the small intestine in animals and in man. The products and probable significance of bacterial digestion are also fully described and discussed.

The account of the peristaltic movements of the intestines and of the nerve mechanism controlling them is well brought up to date, giving briefly the results of the most recent researches in this field.

The final chapter treats of absorption in the stomach and intestines. The channels and mechanism of absorption of different food-stuffs—carbohydrates, fats, and proteids—are fully described. A very interesting epitome is given of the synthesis of the products of proteolysis and lipolysis by means of the intestinal epithelium. The theories with regard to the formation and fate of glycogen in the liver and muscles are critically reviewed. A brief account is also given of the various forms of pathological and experimental diabetes.

The fifth part of the work well maintains the high standard for accuracy and clearness set by its predecessors. J. A. MILROY.

Seta Artificiale. By G. B. Baccioni. Pp. 231. (Milan: Ulrico Hoepli, 1906.) Price L3.50.

THIS is an interesting account of "artificial silk" or "lustra cellulose," an industry which has now assumed serious proportions; in fact, the present production of these new textile threads may be estimated at not less than six tons per day, chiefly manufactured in France, Germany, and Belgium. In the preface it is stated that a Società Italiana della Seta Artificiale in Pavia is the first organisation to undertake developments in Italy. The technology of the industry is briefly outlined in six chapters (pp. 230), attention being chiefly directed to the systems based upon the spinning of collodion (nitrocellulose). The alternative systems, based upon the Cuprammonium and "Viscose" solutions of cellulose, are also described.

The work is a compilation from various sources in the technical literature of cellulose, and makes no claim to an original treatment of the subject-matter. Its appeal will be chiefly to specialists.

The book is original as to binding, for which a silk fabric is employed—as a covering to the humble "board"—the weft of which is a lustra-cellulose yarn.

Zwölf Vorlesungen über die Natur des Lichtes. By Dr. J. Classen. Pp. x+249; diagrams. (Leipzig: G. J. Göschen, 1905.) Price 4 marks.

THESE lectures consist in a series delivered in the winter of 1904–5 in Hamburg to a popular audience. The theme of the lectures is the development of the wave-theory, culminating in the special form of this theory which postulates the essential identity of luminous and electromagnetic waves. The lectures were illustrated experimentally, and a special feature in connection with them is the care taken in devising experiments of a simple and attractive kind. Although they were delivered to a lay public, it must not be supposed that they are popular in the bad sense. They are infused throughout with the scientific spirit; there is no sacrifice of accuracy on the altar of simplicity. The subject is dealt with in a way which must have proved very welcome to the non-professional listener who had some very elementary knowledge of it and desired to have the fundamental experimental facts brought before him in a consecutive way. Geometric propagation, dispersion of colour, interference and diffraction phenomena, double refraction and polarisation, electric oscillations and their quasi-optical properties, the explanation of the demonstrated relations between electrical conductivity and the optical properties of metals—these, in brief outline, are some of the chief phenomena which are expounded. Each experiment is described with the help of a diagram.

We have little but praise for this somewhat unpretentious volume. We note only that the devices attributed here (as usual) to Lecher and Blondlot are essentially the same as that employed previously by Sir O. Lodge in the investigation in which he was engaged when Hertz published his demonstration of the possibility of producing electromagnetic waves.

A la Poursuite d'une Ombre. By Prof. Moye. Pp. 98. (Montpelier: G. Firmin, 1905.)

IN the seven chapters contained in this volume Prof. Moye gives a popular account of the observations made by the Société astronomique Flammarion de Montpelier, at Alcalà de Chisbert, during the total eclipse of the sun on August 30, 1905. The eclipse party consisted of eleven persons, who made a series of valuable observations of the corona and the chromosphere with portable telescopes, spectroscopes, and cameras, and with the naked eye.

In addition to the account of the actual observations, the author discusses eclipse phenomena in general at some length, and gives the results obtained by previous observers since the commencement of detailed eclipse work. A number of drawings and photographs illustrate his remarks.

To anyone unfamiliar with solar eclipse work who desires to make a general survey of all the associated phenomena, and the methods employed in observing them, the book will afford a useful introduction to the subject, and will give him just an insight into the present theories concerning the different portions of our luminary.

Ueber Vererbungsgesetze. By C. Correns. Pp. 43 (Berlin: Gebrüder Borntraeger, 1905.) Price 1.50 marks.

ALTHOUGH only six years have elapsed since De Vries re-discovered the laws of heredity originally propounded by Gregor Mendel, Abbot of Brünn, in 1866, the subject has received so much attention—and in this country especially valuable work has been carried out—that many accounts of the general principles have been written. Prof. Correns, one of the foremost workers on the subject, publishes in this brochure the substance of a lecture delivered at Meran, dealing almost entirely with the botanical side. The account does not go far beyond Mendel's propositions, but the subject of *cryptomeric* is explained with the help of an excellent coloured plate of flowers of Mirabilis, and the writer refers to Galton's theory and the extent to which characters *mendelise, i.e.* develop according to Mendel's laws.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Diurnal Variation of Ionisation in Closed Vessels.

THE connection between the periodicity in the ionisation in closed vessels and the variation in the intensity of the electric field near the earth's surface suggested by Messrs. Campbell and Wood in NATURE of April 19 (p. 583) may readily be explained on the theory of conduction through gases if we assume that the ionisation is caused by radiation from extra-terrestrial sources.

The view of the origin of the earth's field which appears to be in closest agreement with the facts is that it arises in rainy regions on account of the negatively charged rain conveying its charge to the earth, which thus becomes negatively charged. This leaves a high positive potential in the atmosphere immediately above the rainy region which very rapidly distributes itself over the earth's surface by means of discharges in the upper regions of the atmosphere where the pressure is low enough for ionisation by collisions to occur. Owing to the high conductivity of the upper regions of the atmosphere, therefore, the potential will differ only to a relatively slight extent over different regions of the earth's surface; most of the fall of potential between the positive charge over the rainy region and any point of the earth's surface will occur in the badly conducting layer of air at a high pressure, which is comparatively close to the earth's surface.

The above theory is due to Mr. C. T. R. Wilson, with whom I have recently discussed the matter. The explanation of the connection between the earth's field and the ionisation in closed vessels which follows might be made to fit other views of the nature of the earth's field, but I have selected Mr. Wilson's, as it appears to be the most probable.

The distribution of the earth's field, then, reduces itself to a case very similar to that between two plane electrodes immersed in a gas and maintained at a constant difference of potential. Consider what happens if we increase the ionisation near one electrode to a greater extent than that near the other. The potential gradient will become smaller where the ionisation is greatest, and conversely. In the case of the earth the ionising rays presumably come from extra-terrestrial sources, and will be absorbed to some extent by the earth's atmosphere. They will therefore be more intense further away from the earth's surface, and when for some reason or another they increase in intensity they will increase the ionisation at a point some distance from the earth's surface to a greater extent than at a point near to it. From what has been said above, an increase in the ionising rays should therefore produce an increase in the electric intensity close to the surface, and *vice versâ*.

This corresponds exactly with what Messrs. Campbell and Wood have found to be the case; the maxima and minima in the earth's electric field are simultaneous respectively with the maxima and minima in the ionisation in a closed vessel.

It may be of interest to add that Borgmann (*Jurn. Russk. Fisik. Chimičesk. Obščestva* [physical part], xxxvii., No. 4, pp. 77–98, 1905) has also recorded a minimum at about 3 p.m. in the ionisation in a closed vessel. The fact that the time is nearly the same at Cambridge and St. Petersburg seems to indicate that the ionisation is caused by radiation coming from the sun. The fact that the daily variations in the earth's field are conditioned by the sun has already been remarked by meteorologists (*cf.* Arrhenius, "Kosmische Physik," ii., p. 890).

I wish to point out finally that the above explanation of the changes in the earth's field does not depend essentially on radiation coming from extra-terrestrial sources. Any cause which simultaneously increased the penetrating radiation near the earth and the ionisation further away from it would work in the same way.

O. W. RICHARDSON.

Trinity College, Cambridge, April 22.

The New Spot on Jupiter.

THE recent outbreak of dark material in the north equatorial belt and north tropical zone of Jupiter has further intensified, and forms a very prominent and striking feature in the region north-following the red spot. The slanting belt, alluded to in my letter published in last week's NATURE (p. 584), appears to be rapidly extending in a longitudinal direction, and the large dark oval spot on its following side has been several times re-observed here. Transits were obtained as under:—

	h. m.	Longitude
April 15	6 8	75·2
20	5 22	77 5
22	7 2	77·7

The rate of motion appears, therefore, to conform very nearly with that of the red spot and of system ii. of Crommelin's ephemerides (9h. 55m. 40·6s.). On April 20 the north tropical spot was very distinctly seen nearly two hours before sunset, and the transit obtained on that date was regarded as accurate.

The preceding side of the slant-belt is moving much faster than the north tropical spot, and it is highly probable that in a few weeks a new and conspicuous belt will have formed and entwined itself completely round the planet. In this phenomenon we have a repetition of that observed in the spring of 1860 (see Monthly Notices R.A.S., April, 1860, and December, 1898, vols. xx., p. 244, and lix., p. 76).

W. F. DENNING.

Bristol, April 23.

Utilisation of Nitrogen in Air by Plants.

YOUR reviewer (p. 531) of the above work has, like others, failed to furnish any proof against my theory of the fixation of free nitrogen by plants. He desiderates direct chemical proof of the increase of nitrogen in the plant, beyond the nitrogen that is provided by the seed and the soil. Those acquainted with agricultural chemistry know the difficulty of directly determining a slight increase in the quantity of nitrogen, in the circumstance of the comparatively large quantity of nitrogen in the soil necessary to produce a vigorous plant, and they will understand how difficult it is to produce such proof; with the greater information now available, however, it may now be forthcoming. But for this difficulty, the fixation of nitrogen would have been found out long ago.

The experiments at Rothamsted conducted by Lawes and Gilbert are identified with the subject of nitrogen. The idea of the inability of plants to fix free nitrogen is largely based on their experiments. As mentioned in a book written by the recently appointed director at Rothamsted—Mr. A. D. Hall—it occupied their minds "from the very beginning of their experiments until the end." It was their "dominant idea." I may therefore refer to experiments carried out there which show that Lawes and Gilbert themselves found (as many others have done) an increase in nitrogen in growing crops, the source of which could only be ascribed to the atmosphere; thus (see p. 10), "As a result of three years' cropping with barley and clover, and then with clover only, an average amount of 319·5 lb. of nitrogen was removed, yet the soil contained, on analysis at the end of the experiment, 2832 lb. of nitrogen per acre in the top 9 inches, or a gain of 175 lb per acre in the three years, making a total, with the crop removed, of nearly 500 lb. of nitrogen per acre to be accounted for." This was a troublesome fact. It was sought to be explained by the tubercles on legumes, but that an increase was got without legumes is shown by another set of experiments (see p. 8):—"the various crops were grown continuously with mineral manures, but without any supply of combined nitrogen; the following average amounts of nitrogen per acre were taken away:—

			lb.
"Wheat	24 years		22·1
Barley	24 ,,		22·4
Root Crops	30 ,,		16·4
Beans	24 ,,	of which two fallow	45·5
Clover	22 ,,	6 crops only	39·8"

Here again was an increase, and one which legume tubercles could not be brought in to explain. It was only when Lawes and Gilbert, trying to get chemical evidence, grew feeble, unnatural plants under unnatural conditions that they failed to get a similar increase of nitrogen. On this ground alone they supported the theory of the inability of the plant to draw nitrogen from air, and thus supported themselves in the notorious controversy with Liebig, the distinguished German who has done more for agriculture than any other man of science, and who, by the way, denounced the Rothamsted experiments in no measured terms (see the "Natural Laws of Husbandry," pp. 157 and 298).

Obviously, therefore, to show that plants fix free nitrogen is to undermine the work with which Rothamsted is chiefly identified.

Your readers will understand the value of the critique when they know that the initials under it are those of the director at Rothamsted. THOS. JAMIESON.

Glasterberry, Milltimber, April 10.

I AM glad to see that Mr. Jamieson does recognise the necessity of some proof of his assertion that nitrogen has been fixed by the plants he has been examining; he now says that "it may now be forthcoming." When Mr. Jamieson's "may" has been converted into "is," chemists and botanists may begin to consider his speculations as to how the process is effected. For let us bear clearly in mind that Mr. Jamieson's theories only deal with the question of *how* the nitrogen is fixed; that it is fixed at all he takes for granted.

But what an unlucky series of experiments to enforce his argument has Mr. Jamieson selected from Rothamsted. He quotes three non-leguminous crops, wheat, barley, and roots, which when grown continuously on the same land for a period of twenty-four to thirty years have removed on the average 16 lb. to 22 lb. of nitrogen per acre per annum. But at the beginning of the experiments the soil was estimated to contain about 3000 lb. per acre of combined nitrogen, *i.e.* five times as much as the thirty years' cropping has removed. Furthermore, analyses have been made and published which show that the soil has lost nitrogen during this period; the average loss on the unmanured wheat plot from 1865 to 1893 was 10 lb. per acre, which if added to the 5 lb. per acre of combined nitrogen brought down by the rain pretty well accounts for the 19 lb. per acre removed in the crop. Knowing as we do that there are great reserves of nitrogen in the soil, and that they slowly become available for the plant, there is no reason to suspect that these non-leguminous plants have needed to take any nitrogen from the air to yield the crops that are recorded.

Then Mr. Jamieson quotes the output of nitrogen from two leguminous crops, clover and beans, and it is just about double that of the non-leguminous crops; very much more than double, in fact, if calculated on the number of crops actually obtained, and not spread over an average of years. Yet Mr. Jamieson goes on to say that the "legume tubercles" cannot be brought in to explain this; when the only crops yielding anything like an average amount of nitrogen are the two, beans and clover, which by accepted theories obtain nitrogen from the air by means of the bacteria in the "tubercles" on their roots. Most people regard these experiments as a very sound piece of evidence for the fixation of nitrogen by leguminous crops alone.

Let us consider these results from another point of view; the wheat crop without nitrogen, but with phosphoric acid and potash, at Rothamsted averages about fifteen bushels per acre, barley about twenty bushels per acre, the root-crops (mangels) about 5·4 tons per acre; this is the sort of level that is reached when the crop has to rely upon the air and the original stock of nitrogen in the soil. Is Mr. Jamieson proposing to recommend farmers to grow crops of this size, for that is what they must come to when they have only the air to draw upon for their nitrogenous food?

In his concluding paragraph Mr. Jamieson appears to suggest that Lawes and Gilbert ran the Rothamsted experiments as a sort of conspiracy to disguise the truth in favour of a prepossession of their own, and that after their death the body of scientific men who constitute the committee of management engaged their present director to continue the traditional fraud; this is a "theory" which, like others of Mr. Jamieson's, must require a robust confidence in the credulity of his disciples. A. D. H.

A Horizontal Rainbow.

I SHALL be much obliged if a reader of NATURE will kindly give me an explanation of the following:—

I was on Loch Lomond yesterday, a perfectly still, cloudless day, with haze as from east wind over the mountains. There had been hoar-frost in the morning. About 10.15, from the deck on the steamer at Balloch, I observed a broad patch of strong prismatic colours on the absolutely calm surface of the loch about half a mile from the pier, my back being turned to the sun. I watched this patch with interest, and, as the steamer approached it, it gradually lessened and almost disappeared; but in its place a rainbow, faint but distinct, lay horizontally on the surface of the water, one end resting beside the bow of the steamer and the arc curving for perhaps 150 yards ahead, the sun still being behind me. I never saw anything of this kind before, and was much interested. The loch was absolutely calm, reflections of sea-gulls, &c., being perfect.

The only explanation I can think of is that, after the hoar-frost and possible sea-fog of the earlier morning, there was just a film of fog left undisturbed on the calm surface of the water, sufficient to break up the rays of the sun into their component parts. W. R. M. CHURCH.

Western Club, Glasgow, April 12.

THE SAN FRANCISCO EARTHQUAKE OF APRIL 18.

IN the immediate presence of a great catastrophe, in which hundreds of lives have been lost, and San Francisco, the "Queen of the Pacific," has been almost entirely destroyed, it is not to be expected that details of much scientific value should be recorded. All that is here possible is to describe briefly the course of events, to trace in rough outline their connection with former shocks and with the geological history of the district, and to refer to the unfelt earth-waves registered at distant observatories.

NATURE AND EFFECTS OF THE EARTHQUAKE.

Though the coast of California from San Francisco to Los Angeles is one of the chief seismic regions of the globe, the first and greatest shock was heralded by no warning tremors or earth-sounds. It occurred at 5.13 a.m. (that is, 1.13 p.m. Greenwich mean time), perhaps, as the seismographic evidence would imply, a few minutes earlier. As in all tectonic earthquakes of the first magnitude, the duration of the shock was considerable, not less than two or three minutes, and it was in this time that the chief part of the destruction, so far as it was directly due to the earthquake, was accomplished. Five minutes later another and less violent shock was felt, and, in the midst of almost continuous tremors, a third prominent shock took place at 8.15 a.m., and others shortly before 10 a.m., and about 1.30 and 7 p.m. None of these seems to have been registered in European observatories, but they sufficed to throw down walls already damaged. Soon after the first shock fires broke out in several parts of the city, and spread rapidly, the water-mains having been injured. Attempts, on the whole successful, were made to limit their extension by blowing up passages through the crowded parts, with the result that about one-quarter of the city may be ultimately saved.

Like Charleston, which was so seriously damaged by an earthquake twenty years ago, San Francisco is

built upon a peninsula; and the effects of the two shocks, as revealed by the distribution of the damage, were very similar. Although the whole of both cities suffered severely, the chief destruction was confined to houses built on low-lying "made" land. In San Francisco this land is occupied by business houses and warehouses, and, in the southern part, by cheap tenements and poorly-built lodging-houses. At 5 a.m. most persons were in bed, and thus there was little loss of life in the business district, and much in that covered by the tenements. The better-class residential district, situated on the hills, escaped with comparative impunity, so far as the earthquakes were concerned, though the fires afterwards spread to that quarter.

That San Francisco was situated within or close to the epicentral area is shown by the continuous after-shocks, and by the effects of the shock. Observers in the open air state that the streets could be seen to bulge and wave as if about to crack open. Three miles of railway have sunk out of sight between Suisan and Benetia; several railway tracks have been destroyed for scores of miles; and on the harbour-front the earth appears to have sunk from six to eight inches. Great cracks were formed in the streets, and these cracks were twisted into all shapes. The houses, before they were destroyed by fire, were also seen to be out of alignment.

Outside San Francisco many towns are known to have suffered severely, especially San José, Santa Cruz and Santa Rosa; others less seriously, from Mendocino on the north to Monterey on the south. With our present information (and the absence of news from neighbouring places, and especially from the Lick Observatory, is disquieting), the meizoseismal area is a band extending along the coast and parallel to the Coast Range, about three hundred miles in length and not more than fifty miles in width. The extent of the disturbed area will remain unknown until inquiries have been made, but it is curious how few details on the subject have yet been published. Los Angeles (only 350 miles S.E. of San Francisco) does not seem to have been affected to any extent by the principal earthquake, though the shock was felt severely throughout the whole of the neighbouring State of Nevada, and there are vague reports of more distant observations.

Position of the Epicentre and Seismic Sea-Waves.

If the line drawn so as to bound the known area of destruction be even approximately correct, there can be no doubt that the epicentre was submarine and situated some little distance from the coast. The fact that the shock was felt at San Francisco two or three minutes after the epicentral time implied by the seismic records is also in favour of this conclusion. The chief difficulty in accepting it lies in the absence of any very great sea-waves. Much of San Francisco is only about twelve feet above high-water mark, and would have been submerged by any considerable wave. There seems, however, to have been some disturbance of the sea. Many vessels, it is said, were washed ashore with each disturbance, and washed out again by the receding waters. There are also unconfirmed reports that Terminal Island, a seaside resort about twenty miles from San Francisco, has been destroyed by a sea-wave, and that other places on the Californian coast have also been swept away. At present it is probable that the first decisive evidence of sea-waves, if any existed, will come to us from the eastern shores of Japan, which would be reached by them in about ten and a half hours after the earthquake.

Geological Relations of the Earthquake.

The earthquakes of California have been studied for some years by Messrs. Holden and Perrine, of the Lick Observatory, and the geology of the State is being revealed through the labours of Messrs. Russell, Diller and Lawson; while an admirable summary of their relations was recently presented in M. de Montessus' valuable work on "Géographie séismologique" (pp. 404–412). Between the Rocky Mountains and the Pacific are the parallel chains of the Sierra Nevada and the Coast Range. Among the Rocky Mountains earthquakes are few and slight; on the eastern slopes of the Sierra Nevada they are more frequent, and sometimes, as in the Owen's Valley earthquake of 1872, of considerable severity. The western portion of the Sierra Nevada, the Cascade Range, is remarkably free from earthquakes, though it is worth noting by those who see an intimate relation between volcanic and seismic actions that it contains the recently extinct cones of Shasta, Mount Hood and Mount Rainier. Again, the Coast Range, and especially the districts surrounding San Francisco and Los Angeles, is one of the great seismic regions of the globe. Lastly, to the west of California the sea-bed deepens rapidly, the contour of 4000 metres lying only a short distance from the land, and from this region many of the strong Californian earthquakes are known to proceed.

Recent studies have established a close connection between these earthquakes and the geological structure of the district. Whether the earthquakes take place under the Coast Range or beneath the adjoining ocean, the longer axes of the isoseismal lines are either parallel or perpendicular to the sub-oceanic contour-lines, the crust-folds of the Coast Range and the long lines of fault of the Pacific seaboard. It is difficult to resist the conclusion that in the western United States we are presented with mountains in four successive stages of growth. In the Rockies we have ranges so ancient that they have almost ceased to grow; in the Sierra Nevada to the west another which is approaching old age; the Coast Ranges are in the stage of youthful, vigorous growth, with the possibility of a long and active life before them; while, still farther to the west and not yet risen above the ocean, there seems to lie an embryonic range, of which the San Francisco and other earthquakes are the birth-throes.

The Unfelt Earth-Waves.

In all parts of the world delicate seismographs soon afterwards recorded the occurrence of a violent earthquake. The first waves reached Victoria (B.C.) at 1.16 p.m.; at Washington the movement was so strong that the pen passed off the recording sheet. In a quarter of an hour the seismographs of Great Britain took up the tale, large disturbances being recorded at Shide, Bidston, and Edinburgh; at Birmingham the pointer of the Omori horizontal pendulum swept three times off the drum. Passing over to the Continent, they set to work the instruments at Berlin, Heidelberg, Vienna, Laibach, Turin, Rome, and many other places. The pendulums at Florence shared the fate of those at Washington and Birmingham. The seismograph at Cape Town also registered the movement, while those in Japan were disturbed by the waves proceeding in the opposite direction across the Pacific. Only the scantiest details are as yet made known, but, if we may judge from the diagram at Birmingham, the complete series of records will be one of great interest and value.

The first series of preliminary tremors reached Birmingham at 1h. 25m. 3s. p.m. (G.M.T.); they were

small in amplitude and had an average period of 6·4 seconds. At 1h. 35m. 7s. they were followed by the second series of preliminary tremors, much larger in amplitude and with an average period of 11·4 seconds. These tremors, as is now well known, traverse the body of the earth with velocities of about 10 or 11 and 5 km. per second respectively. At 1h. 45m. 13s. began the principal portion of the movement, consisting of undulations which travel over the surface with a nearly uniform velocity of 3·3 or 3·4 km. per second. In the initial phase of this portion the undulations had an average period of 44·1 seconds; in the slow-period phase (which began at 1h. 50m. 22s.) of 25·2 seconds, and in the succeeding quick-period phase of 16·2 seconds. Unfortunately, this portion of the record is incomplete, for the pointer of the pendulum swept off and on the drum three times, several waves being thus lost, and the initial epoch of the quick-period phase cannot be determined. The end-portion of the disturbance began at 2h. 1m. 4s., and consisted of a long series of unusually clear and regular waves with an average period of 15·0 seconds. The duration of this portion is uncertain, for these waves were reinforced at 3h. 28m. 38s. by the undulations of the principal portion which travelled through the antipodes along the major arc joining San Francisco and Birmingham. At 3h. 56m. 57s., however, the trace becomes nearly steady, but a careful examination reveals another series of long, low undulations from 4h. 58m. 32s. to 5h. 6m. 34s., which represent the return of the first series of surface-undulations after they had completed the tour of the globe and travelled once more as far as Birmingham. The interval between the first and third passages of these waves is 3h. 13m. 19s., and corresponds to a mean velocity of 3·36 km. per second.

MAGNITUDE OF THE SAN FRANCISCO EARTHQUAKE.

The mere fact that the earth-waves should disturb a seismograph after travelling 30,000 miles is sufficient evidence to show that the earthquake belongs to the very front rank. If we might estimate the intensity of a shock by the maximum range of movement at Birmingham, we should have to regard the San Francisco earthquake as much stronger than the Indian earthquake of April 4, 1905, but as inferior to the remarkable Central Asian earthquakes of July 9 and 23, 1905. The period of the larger waves approaches, however, so closely to that of the pendulums themselves that it by no means follows that the range and epoch of the maximum displacement of the instruments correspond with those of the earth's crust. Nor can we infer much from the extent of the destruction of the lofty, badly-founded houses of San Francisco. If the Colchester earthquake of 1884 had originated beneath the city and west-end of London instead of beneath the villages of Peldon and Rowhedge in Essex, the damage would have been considerable, and the earthquake would have held a higher place in our estimation. When, however, we consider the great area covered by the injured towns in California, the displacement of the superficial soil, the crumpling of the railway tracks, and the widespread registration of the unfelt waves, it is clear that we must give to the San Francisco earthquake a place inferior, no doubt, to the Lisbon earthquake of 1755 and the Indian earthquake of 1897, but probably one in the same rank as the Neapolitan earthquake of 1857, the Japanese earthquake of 1891, and the Indian earthquake of 1905.

C. DAVISON.

THE LIFE OF THE AUSTRALIAN BLACKS.[1]

BOTH for the anthropologist, who wants well-sifted and trustworthy material, and for the ordinary reader who would like to know something about the life of the native Australian, this is a most useful book. In fact, for the latter purpose it may be said to stand entirely alone. There is no other work on the Australians which gives anything like so good a general view; it is clear of superfluous technicalities, eminently readable, and written with so much sympathy that we cease to be surprised at the success of the writer in getting at such secret matters as male initiation ceremonies and beliefs about Byamee, all of which are strictly forbidden lore to the Euahlayi woman. Mr. Lang's introduction explains the bearing of the book on current controversies.

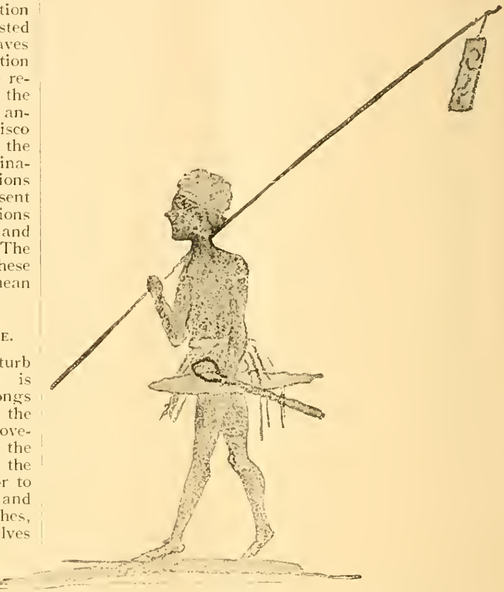

FIG. 1.—A native carrying a message-stick. From "The Euahlayi Tribe."

Besides these two important subjects, Mrs. Parker has much to tell us about the social organisation, magicians and their initiation, a witch woman whose feats are distinctly mystifying, the life of children of both sexes up to and including the initiation ceremonies, burial customs, dress, amusements, the provision of food, and mythology; and on many points we learn something which throws light on previous knowledge. Although we hear nothing of the so-called sex-totem among the Euahlayi, they hold that the male children are made by a lizard, the female by the moon, who is sometimes assisted by the crow. This looks like the raw material of the sex-totem. It

[1] "The Euahlayi Tribe, a Study of Aboriginal Life in Australia." By K. Langloh Parker; with an Introduction by Andrew Lang. Pp. xxvii+156; with 6 illustrations by a native artist. (London: A. Constable and Co., Ltd., 1905.) Price 7s. 6d. net.

may be noted that the lizard is one of the forms of the sex-totem in South Australia. In connection with children, it is interesting to note that we have in the Euahlayi a variant of the Arunta belief recorded by Strehlow, which has also a close connection with the belief of the northern Arunta visited by Spencer and Gillen.

An important subject, on which little information was previously available, is that of the *yunbeai* or individual totem, which is usually confined to medicine men, but among the Euahlayi is held to be granted to their special favourites. More important still is the information about Byamee. Unless Mrs. Parker's evidence can be impeached on the ground of European influence, it will henceforth be impossible to deny that the Australians have gods and a religion. We learn from this work that prayers are offered to Byamee both at the Bora and at the funerals of men.

Mrs. Parker alludes to the boomerang, and provides mathematicians with another problem in the shape of the performances of the *boodthul*, a miniature club which travels further if it is thrown through the top of a bush than if it has an unimpeded flight. The book contains six illustrations by a native artist. Mrs. Parker does not mention them, but she has informed the present writer that the artist had no European training. It may, however, be surmised that he had seen European pictures. N. W. T.

BORIC ACID AS A FOOD PRESERVATIVE.[1]

THE report of the English departmental committee on the use of preservatives in foods contains voluminous evidence on the harmful nature of most of the antiseptics employed in commerce. It was issued in 1901, and among its recommendations one finds that the use of any preservative in milk should be constituted a punishable offence. It, however, makes an exception in the case of butter and cream, which are substances taken in relatively small amounts, and allowed 0.5 per cent. of boric acid in the former, and 0.25 per cent. in the latter case.

Those who have had the time to read the evidence will be struck with the almost complete unanimity of the medical witnesses on the harmful effects produced by boric acid and its compounds. Unfortunately there will always be some who disagree with the majority, and it is particularly unfortunate from the point of view of the public welfare that one of these is Dr. Oscar Liebreich, whose opinion is on most subjects entitled to careful consideration and respect. The special pleading on behalf of boric acid and borax contained in Dr. Liebreich's former publications are repeated in the pamphlet just issued, and we fear that the useful work of those who are trying to prevent adulteration, and protect the public from those tradesmen who cover their misdeeds and want of cleanliness by the employment of antiseptics dangerous to health, will be seriously impeded thereby.

The question has also become an acute one in America, and the United States Department of Agriculture appointed Dr. Wiley, their principal chemist, to investigate the matter on a large scale by experiments on human beings, over a long period. Dr. Wiley's report was most unfavourable to the use of these preservatives; the ill-health set up in the subjects of his experiments, and the alterations in bodily metabolism to which this was due, are described in detail, and furnish systematic evidence on the subject which confirms what was known from clinical experience, and to those who had experimented previously on animals. To the unprejudiced observer Dr. Wiley's report settled the matter once and for all.

The special object of Dr. Liebreich's new brochure is to criticise some details in Dr. Wiley's work. This is always an easy thing to do when the subjects of an experiment are numerous, and in the human subject in particular it is often difficult to obtain precise details. Some of these, on account of the ill-health set up by the drug, had to abandon the continuation of the observations. This obviously reduces the number of observations, but at the same time is in itself a striking piece of evidence against the continued use of borax and boric acid. Dr. Liebreich does not dispute the ill-health of Dr. Wiley's willing subjects, but he is driven to attribute this to other causes, like inefficient hygienic surroundings. He does not dispute the loss of body weight, but says this is not by any means always injurious.

Those interested in this most important question should of course read both sides, and one sincerely trusts that in this instance the weight of a great name will not be allowed to overbalance the all but universal testimony of others to the contrary.

[1] "Third Treatise on the Effects of Borax and Boric Acid on the Human System." By Dr. Oscar Liebreich. Pp. vii+70. (London: J. and A. Churchill, 1906.) Price 5s. net.

PROF. W. F. R. WELDON, F.R.S.

THE 'seventies of last century may be said to have witnessed the renaissance of biological studies in Cambridge. It was in the year 1870, if we mistake not, that Michael Foster, at the invitation of Trinity College, became prælector in physiology and founded the great school for which the university has since been famous. Of his pupils the greatest was F. M. Balfour. He very soon became the centre of a new system which was thrown off, so to speak, from the main body, and rapidly acquired form and influence.

Weldon was one of the most distinguished products of the zoological school which was in this way established. He was the son of Mr. Walter Weldon, F.R.S., the distinguished chemist, and was educated at King's College, London. He entered at St. John's College, Cambridge, in 1878, of which foundation he became first a scholar and in 1884 a fellow. After taking his degree in 1881 he at once threw himself with characteristic vigour and disinterestedness into zoological teaching and research. He became demonstrator in comparative anatomy in 1884, and held the office for one year. In 1885 he was appointed to the newly-established lectureship on the morphology of the invertebrata, which office he held until he left Cambridge in 1891. As a lecturer Weldon is not likely to be forgotten by those who heard him. He was remarkable for the ease and mastery with which he handled his subject, and for the earnestness and clearness of his teaching. It was impossible to sit inert under him; he had the gift of compelling attention.

Weldon's early researches were mainly concerned with morphological problems, the study of which had been so strongly stimulated by the work of Darwin. In the 'sixties, 'seventies and early 'eighties of last century the hope existed that it would be possible by minute morphological study actually to trace the pedigrees of existing organisms and to get some comprehension of the wonders and complexities of animal structure. In the 'eighties, however, with the progress of experience it began to be obvious that these hopes could not be realised, that the problem could not be solved by morphology, and that we must turn to other sources if we wanted to progress in ideas. Weldon was soon touched by the scepticism which thus arose, and cast about in the latter part of his time at Cambridge for new methods. These he saw must come in part at least from an exact study of variation, and

his work was henceforth mainly directed to that subject. He spent his vacations at the laboratory of the Marine Biological Association at Plymouth and in the Zoological Laboratory at Naples, and devoted himself to laborious and systematic measurements of the parts of various marine organisms. These researches were continued with increased vigour at University College, London, where in 1891 he succeeded Prof. Ray Lankester as Jodrell professor of zoology. Here he entirely fulfilled the expectations which had been formed of him at Cambridge. Effective and enthusiastic as a teacher, he soon gathered around him a body of young workers whom he inspired by his own intensive fire.

During his career at University College he played a leading part in initiating the changes which, after some set-backs, resulted in the recent reorganisation of the University of London as a teaching body. In the completion of this most important work he was debarred from active participation, for in 1899 he was appointed the Linacre professor of comparative anatomy in the University of Oxford.

At Oxford he devoted himself with signal success to the duties of his professorship, paying special attention to the subject of variation. He again formed the centre of an active school of research, and founded in conjunction with Prof. Karl Pearson the journal *Biometrika* to advance the subject which he had so much at heart. Of his biometric work much might be said, but this must suffice. He was the one English biologist who actually realised what the whole attempt to give quantitative exactness to biological concepts really means; and he was the first to calculate organic coefficients of correlation and to suggest their important bearing on evolution.

Weldon held the chair at Oxford until his death on Good Friday last, after an illness of little more than twenty-four hours. He was born in 1860, and was therefore a comparatively young man when he died. He had about reached the stage of life when the germinating processes of the brain have attained their maximum and the mind begins to take stock of its ideas and to seek for means of coordinating them and of so bringing them before the world. He had several works on hand, all of which are unfinished. The most important, perhaps, is that in which he hoped to set down the conclusions he had reached on the great subject of the origin and the handing on by heredity of the properties of organisms.

His work, therefore, is not finished, but of whom can it be said that his work is finished? He has at least carved out the steps by which others will mount. He has sown the seed. It is for us who remain and for those who come after us to reap the fruits of his labours.

He was essentially a good man, and happiness was his portion in this life. Blessed in his domestic circumstances, and in holding one of the most distinguished positions the zoological world has to offer; in the possession of good health, of considerable bodily strength and activity, of indomitable energy, of a quick and penetrating intellect which rendered all intellectual effort pleasurable, of acute literary and artistic instincts, of a simple, honest, and lovable nature which endeared him to all who came in contact with him, he had everything which is necessary for earthly happiness. So amply had nature lavished her gifts upon him that he might well have been counted among her spoilt children. But he was lofty in his aims and strenuous in his life. His early death is a grievous blow to science; to his friends it is an affliction hard to be borne; to those who loved him it can only appear as a cruel and unnecessary calamity; but yet, can we say that he was not happy in his death, as in his life?

> Under the wide and starry sky
> Dig the grave and let me lie,
> Glad did I live and gladly die
> And I laid me down with a will.

PROF. PIERRE CURIE.

M. PIERRE CURIE, co-discoverer with his wife, Mme. Sklodowska Curie, of the element radium, and the investigator of many of its properties, met his death as the result of a street accident in Paris on Thursday, April 19. He was crossing the Place Dauphine when he was knocked down by a cab and fell under a heavy van coming from the opposite direction. The wheels passed over his head, and when taken to the police station life was found to be extinct.

Cut off in the midst of a career of active scientific investigation, in the flower of life and at the height of a unique reputation, brilliantly won and universally acknowledged, his death will be mourned by the whole civilised world. In this country, where the importance of his work and discoveries was early and fully recognised, and where the fame attaching to his name has spread widely, deep sympathy will be felt for Mme. Curie in her tragic bereavement, coupled with a sense of loss that a partnership in science so illustrious and fruitful has been brought to so untimely a close.

Born in Paris on March 15, 1859, Pierre Curie received his early education at the Sorbonne, where he attained the degree of Doctor of Science. He was made professor of physics in the Municipal School of Physics and Chemistry in Paris in 1895, and in 1900 he became professor at the Sorbonne. His earlier researches, extending over the period 1885–1894, included investigations into the phenomenon of piezo-electricity, in conjunction with his brother, J. Curie, the construction and use of electrometers and guard-ring condensers, the magnetic properties of iron, oxygen, and other substances at different temperatures, and the construction of sensitive aperiodic balances.

In 1895 M. Curie married Marie Sklodowska, one of the senior students at the Municipal School, where he was professor, and joined his wife in the new field of research opened up by M. Henri Becquerel's discovery of the radio-activity of uranium and its compounds. From 1898 onwards appeared the remarkable joint publications dealing with the discovery of radium and the investigation of its properties. The great advances made by the two investigators in this field may be traced to the collaboration of a trained physicist and a skilled chemist in a subject which may truly be described as a meeting ground of the two sciences. M. Curie's earlier results on piezo-electricity, and the construction and use of electrometers and condensers were ingeniously applied to the requirements of the new work, and in his hands resulted in a ready and trustworthy method for the electrical measurement of radio-activity being worked out. In the detection and initial stages of the separation of radium and polonium in pitchblende, the method accomplished what in the hands of Bunsen the spectroscope had accomplished in the detection and separation of cæsium and rubidium in the waters of Durkheim. When sufficient radium had been obtained, M. Curie and his pupils investigated the physical properties, while Mme. Curie devoted herself to the more purely chemical problems, the determination of the atomic weight of the new element, and the attempt to separate polonium.

M. Curie's most important contributions to the study

of the nature of the new element comprise the discovery, in conjunction with Mme. Curie, of the so-called induced activity conferred by radium on surrounding objects, and the proof that the penetrating radiations transport negative electricity even after they have been made to pass through a sheet of metal connected to earth. In conjunction with M. Laborde he discovered and measured the spontaneous evolution of heat from radium compounds.

In 1903 the Davy medal was conferred by the Royal Society on M. and Mme. Curie, and they shared with M. Branly the Osiris prize, and with M. Becquerel the Nobel prize for physics. M. Curie was made a member of the Institute of France in 1905. He will be remembered in this country for the lecture on radium, delivered with characteristic modesty and simplicity of manner, at the Royal Institution in 1903. He refused the Cross of the Legion of Honour offered by the French Government, on the ground that he preferred to remain a simple citizen, holding no doubt the view that scientific discovery is its own sufficient reward.

It has been said by a recent writer that there will come a time when men will date the coming in of their kingdom to the day when Curie and Laborde discovered the spontaneous evolution of heat from radium. Certainly no limit can be set to the consequences in the near or distant future which may be expected to flow from the discoveries with which the name of Curie is associated.

Like Röntgen shortly before, Curie emerged at one step from comparative obscurity to universal fame, and what they achieved is still within the horizon of the humblest investigator. Like the soldiers of Napoleon, each of the rank and file of the army of patient investigators carries in his knapsack a marshal's baton. The career of M. Curie illustrates this, and continues as an inspiration and encouragement to others. None have set in motion more pregnant influences. No one stands in less need of the historian to perpetuate his memory. F. S.

NOTES.

In the disastrous earthquake at San Francisco, a detailed description of which is given in another part of the present issue, it is reported that upwards of 1000 persons lost their lives, and that material damage was done to the value of more than sixty million pounds sterling. There seems little reason to doubt that most of these lives and the greater part of the property were lost in the fire which followed the earthquake, and that a little forethought would have prevented, or at least greatly lessened, the awful calamity. Electric mains were broken by the earthquake shock at a time when the current was being supplied, and gas and water mains were shattered. The electric current does not appear to have been stopped at the power stations, and the consequent numerous short circuits which occurred soon inflamed escaping gas and set fire to buildings in many parts of the city. The broken water mains obliterated the water supply, and the only means of checking the fire seems to have been the demolition by dynamite of property in its path. The steel buildings in the city appear to be almost intact. The earthquake did not damage them, and the fire only consumed the woodwork. Despite the rumours which have been in circulation as to damage to universities and observatories in the disturbed area, it is gratifying to know that there is as yet no confirmation of such calamities. Upon inquiry at the Royal Astronomical Society, we learn that no news has been received about any of the Californian observatories. Astronomers are particularly anxious as to the fate of the Lick Observatory, situated as it is very near to the centre of disturbance, and in view of a rumour that has reached a London fire insurance company of serious injury to the observatory. The Solar Observatory at Mount Wilson—near Pasadena, which is ten miles N.N.E. of Los Angeles—is probably too far to the south to have been damaged.

Some changes in the organisation of the Geological Survey of Canada have recently been made by the Premier, Sir Wilfrid Laurier. For more than five years Dr. Robert Bell, F.R.S., has been the acting-director of the Survey, and has managed the business as well as the scientific affairs to the satisfaction of the scientific, mining, and the general public. In this period he has accomplished much valuable work, initiated many useful new features, and raised the standing of the Survey in general estimation. Since the Survey began, sixty-three years ago, about 470 maps have been prepared and issued, and nearly one-third of this number have been published during the past five years, while others are nearly ready. By the change of organisation which has just been instituted, a business administrator has been appointed, while Dr. Bell is given the title of Chief Geologist of the Dominion. Dr. Bell will continue to prepare his reports, maps, and other works, and will have a free hand in geological matters, so that he ought apparently to be congratulated on being relieved of a troublesome and difficult part of his work.

The bi-centenary of the birth of Benjamin Franklin was celebrated by the American Philosophical Society at Philadelphia on April 17–20, in accordance with the programme announced in Nature of March 29 (p. 515). Addresses were read from the universities of Oxford, Cambridge, Glasgow, and Edinburgh, the Paris Academy of Sciences, and many other institutions. A statue of Franklin, presented to the City of Paris by Mr. J. H. Harjes, was to have been dedicated on April 20 at an international festival, in which the French Government had arranged to take part, but the celebrations were postponed in consequence of the catastrophe at San Francisco.

Prof. W. Ostwald has been elected a foreign member of the Danish Academy of Sciences.

Prof. Gabriel Oltramare, who for fifty years held the chair of mathematics at Geneva University, died on April 10, in his ninetieth year.

The death is announced, at sixty-five years of age, of Dr. N. S. Shaler, professor of geology at Harvard University and dean of the Lawrence Scientific School.

The annual meeting of the South African Association for the Advancement of Science will be held at Kimberley on July 9–14, under the presidency of Mr. G. F. Williams.

Dr. Dudley Buxton has been elected chairman of the council of the Selborne Society for the ensuing year, during which the society will attain its majority, having been founded in 1885. The annual *soirée* will be held on May 25, when the president, Lord Avebury, will deliver an address.

A telegram from Sarajevo, Bosnia, states that at 11 a.m. on April 19 a short, sharp earthquake shock was felt there. The shock was undulatory in character, and travelled from west to east. An earthquake shock was felt at Grants Pass, Oregon, at 1.11 a.m. on April 23. The Wellington correspondent of the *Times* reports that both the Eastern

Company's cables between New Zealand and Australia suddenly broke on April 23, as the result, it is presumed, of submarine disturbances. A sharp earthquake shock was felt at San Francisco at 10.30 p.m. on the same date. It lasted about three seconds, and the motion was from east to west.

Dr. V. F. L. Matteucci, director of the Vesuvius Observatory, has issued the following reports:—*April* 18.—A very violent squall blew the plume of smoke which hung over Vesuvius on to the observatory, bearing with it a quantity of dust and asphyxiating gases. The crater, though shrouded in thick mist and rain, seems to be quiet. *April* 20.—The shower of ash has ceased and the cloud of dust has dispersed, leaving visible the crater, which continues to eject, though more calmly, globular masses of vapour containing lesser quantities of dust, which fall on the eastern slopes of the volcano. No further shocks have occurred, only very slight movements being reported by the more sensitive seismographs. *April* 23.—The seismic instruments are very steady. The crater is emitting grey vapour, together with small quantities of dust at intervals.

According to the *Chemiker Zeitung*, the number of patents applied for during 1905 in Germany was 30,085 as against 28,360 in 1904, whilst the number of patents fully taken out was 9600 against 9189. Of the different applications, 22,030 were by Germans, 1769 by Americans, 1410 by Frenchmen, 1264 by Englishmen, 873 from Austria, 707 from Switzerland, 473 from Belgium, 249 from Hungary, 246 from Russia, 230 from Denmark, 188 from Italy, 174 from Sweden, 48 from Norway, &c. The largest number of new patents for the year came under the heading of electrotechnics. During the year 8623 patents expired or for other reasons ceased to be worked, while at the end of the year 32,430 patents remained in force.

From Budapest we learn that the director of the Hungarian Chemical Agricultural Institute has presented a strong petition to the Government urging the complete reorganisation of the institute, which was opened twenty-five years ago by the Minister of Agriculture as a central experimental station for agricultural chemistry. In the first instance it is proposed that no further analyses for private persons be undertaken, as this is not only unfair to the private laboratories, but provides so much work for the institute as to hinder members of the staff from following up any line of scientific research. Great stress is laid upon the advisability of bringing all the experimental stations into intimate union with the Imperial Institute of Hungary. According to the director's proposal, the reorganised institute shall be divided into seven departments, each under the supervision of a head chemist.

The Easter party of naturalists and students at the Liverpool Marine Biology Committee's station at Port Erin, in the Isle of Man, has been larger than usual, and the available accommodation in both hatchery and laboratory has been fully occupied. In addition to senior students from the botanical and zoological departments of the universities of Manchester and Liverpool, the following professional workers have occupied tables in the laboratory:—Dr. H. E. Roaf (bio-chemistry), Mr. J. Pearson, Mr. W. Gunn and Prof. Herdman, and Mr. Chadwick, the curator of the biological station. In the sea-fish hatchery the season has been a good one. Although the first fertilised plaice eggs were obtained from the spawning pond on February 13, only one day earlier than last year, embryos in large numbers appeared comparatively early in the season, and the output of young fish is now about a million in advance of the corresponding date in 1905. Five and three-quarter million plaice eggs have now been obtained from the pond, and nearly three and a half million larvæ have been set free in the Irish Sea. The largest number put out on one day was 470,000, on April 20.

The latest report of the Decimal Association, of which Lord Kelvin is a vice-president, states that it is proposed to open a new Parliamentary campaign to prepare the way for the introduction of a Bill in the House of Commons, on the lines of the Bill which has already passed the House of Lords. The report goes on to point out that advocates of the metric system of weights and measures in the United States of America have been encouraged by the introduction of a Bill in the House of Representatives by Mr. Littauer, which provides for the exclusive use of metric weights and measures in all Government departments. This Bill, as has been recorded already in these columns, is now before a Standing Committee of the House of Representatives, and there is every hope that it may be reported on favourably. The executive committee of the association records in the report its thanks to the Association of Trade Protection Societies for its continued advocacy of the compulsory adoption of metric weights and measures. Since this association represents retail as well as wholesale traders, its support may be taken as a distinct refutation of the assertion that the shopkeepers of the country do not wish to see the adoption of the decimal system of measurement. The report mentions also that the Canadian Government has appointed as lecturer a professor of the University of Toronto to devote a year to the task of explaining the metric weights and measures in all the leading cities from Halifax to Vancouver.

Reports are being received of twilight glows and of the deposition of dust, supposed to be due to the recent eruption of Vesuvius. Prof. Stanislas Meunier has collected on the roof of his house in Paris dust said to be identical with the dust of the eruption of 1872. At Southall, Middlesex, Mr. G. Gibson has also collected dust apparently of similar nature. Dr. F. A. Bather, writing from Wimbledon, informs us that on the evening of April 18 the sunset was strongly reminiscent of the Krakatão glows. It will be interesting to learn whether similar observations have been recorded in other localities. The distribution of the dust would depend chiefly upon the upper air currents, which are usually different from those at the surface, and although the surface winds have recently been from north and north-east, the dust may have been carried to north-west Europe by currents in the upper air.

It is stated in the *Cologne Gazette* that the German Government is making preparations for the issue shortly of weather forecasts for agriculturists. The forecasts will be sent free or at a nominal charge, and the success of the undertaking will be judged from returns of the subsequent weather supplied by the recipients of the information. We think this is a step in the right direction; the experiment has already been made with much success in the United States and elsewhere. Prof. Willis Moore, *e.g.*, in an article in the *National Geographic Magazine* for June, 1905, says:—"No large grower of fruits or vegetables is content to be excluded from the receipt of the frost forecasts." During the hay and corn harvest (June–September) special forecasts have been, for many years, issued to farmers in this country by the Meteorological

Office. The only charge now made is for the actual cost of the telegrams, and the success of the work is judged, as proposed in the German scheme, by the returns made by the recipients themselves. From the last published annual report (1904–5) we see that the total and partial success of the forecasts amounted to 92 per cent. for the country generally, and that 58 per cent. were completely successful.

The Bulletin of the Italian Meteorological Society is now issued in two-monthly parts, and includes original contributions and monthly results of observations at a considerable number of stations. The issue for February-March contains an interesting account of the ascents of two unmanned balloons in August last, near Treviso, Venice, in both of which readings were obtained at altitudes exceeding 10,000 metres. The first important inversion of temperature, amounting to 6° C., was experienced between 10,000 metres and 10,385 metres, on August 4, notwithstanding the fact that a few hours previously a very violent thunderstorm occurred at the station. The second ascent was made on August 30, at the time of the solar eclipse; the inversion of temperature was not so marked as in the previous case, but amounted to 3° C. between the heights of 18,000 metres and 20,000 metres. The exact altitude of the inversion during this ascent is somewhat uncertain, as the barometric trace was partially obliterated by the peasants who picked up the records. Thunderstorms were also prevalent about twelve hours prior to the time of this ascent. The discovery of such inversions of temperature is known to be one of the most interesting results connected with the recent explorations of the upper air.

To vol. xxvi., part iv., of Notes from the Leyden Museum, Dr. H. W. van der Weele contributes three papers on Malay Neuroptera, the most important of these dealing with the representatives of the family Sialidæ. Among other notes, Dr. J. G. de Man discusses and redescribes certain Malay crustaceans of the genus Palæmon, while Dr. R. Horst describes a parasitic copepod crustacean of the genus Penella infesting a large fish from the Moluccas.

A hand-list of Philippine birds has been drawn up by Messrs. R. C. McGregor and D. C. Worcester, and published at Manila by the Bureau of Government Laboratories. A slip inserted within the cover announces that the publication of the Bulletins of the Bureau has been discontinued, and that in their place will be issued a new serial, the *Philippine Journal of Science*, while the Bureau itself becomes the Bureau of Science of the Philippine Islands.

The January issue (vol. x., part i.) of the Transactions of the Leicester Literary and Philosophical Society contains a report of the president's address at the annual meeting in October last, in which attention is directed to the decadence of artistic feeling and good taste in the design and execution of architectural and kindred objects in and around Leicester. The contents include a paper by Mr. J. R. Plant on the geological history of molluscs, and a second, by Mr. H. Donisthorne, on Isle of Wight beetles.

No. 1442 of the Proceedings of the U.S. National Museum is devoted to notices of the type specimens of Ordovician and Silurian Bryozoa collected and described by Mr. U. P. James. These fossils, which came from the Cincinnati group, are mostly in the Walker Museum at Chicago, although some are preserved at Washington. According to the author of the paper before us, Mr. R. S. Bassler, the original determinations were for the most part erroneous. Descriptions of new South American moths, by Mr. W. Schaus, of Twickenham, form the subject of No. 1444 of the same serial.

The life-history of the North American cave-salamander, *Spelerpes maculicaudus*, by Messrs. A. M. Banta and W. L. McAtee, forms the subject of No. 1443 of the Proceedings of the U.S. National Museum (vol. xxx., p. 67). This handsome salamander appears to be confined to the Mississippi valley, where, although commonly found in caves, it may occasionally be met with in woods. When in caves, it is generally to be found at no great distance from the entrance, usually but little beyond the twilight zone. For breeding purposes, however, these creatures penetrate deeper into the recesses of the caves, where the larvæ are produced; such full-grown larvæ as are met with in the open country having probably been washed out by freshets. Within caves the adult salamanders are usually to be found in crevices or upon rock-shelves.

The March number of the *Museums Journal* contains an account, by Dr. W. E. Hoyle, of the new zoological institute at Breslau; while Prof. J. T. Wilson's paper on the Australian Museum, Sydney, which was read last year at the Worcester conference, is printed in full. In another article it is stated that Mr. E. Lovett, of Croydon, has formed a large collection of manufactured objects which he is desirous of using as the basis of a "Folk Museum." A schedule is given of the collection of appliances and allied objects used by primitive man, arranged to illustrate the evolution of idea, form, and design, with the amount of superficies required for their proper display in a museum.

In parts i. and ii. of vol. xxxv. of Gegenbaur's *Morphologisches Jahrbuch*, Prof. B. Hatschek, of Vienna, commences a series of studies on the theory of the primitively segmental structure of the vertebrate skull, dealing in this instance with the anterior extremity of the spinal neural system of the lancelet. Dr. Fleischmann's series of papers on the morphology of the cloaca and related organs in the amniote vertebrates is continued by Messrs. H. Dimpfl and J. Schwarztrauber, who respectively discuss these structures in the guinea-pig and the sheep. In a long paper Mr. G. Ruge brings to a conclusion an elaborate series of studies of the external form of the liver in the Primates, dealing in this instance with the monkeys of the Cercopithecus group. As might have been expected, these display a very generalised character in respect to this organ, which is markedly different from that of the anthropoid group. Among other papers on vertebrate morphology is one by Mr. H. Braus on the question whether the formation of the skeleton is dependent on the muscular layer, and a second, by Prof. G. Jelgersma, on the origin of the vertebrate eye. For the conclusions in both these cases we must refer our readers to the original papers, as they are too long to be given here.

The authors of a forthcoming monograph upon "Eclipse"—the famous racehorse—ask us to announce that they would be very glad to be informed of any references to this celebrated horse in contemporary literature; to his breeder, the Duke of Cumberland; to his purchaser, Wildman; and to his subsequent owner, Dennis O'Kelly. The monograph will be as completely illustrated as possible from contemporary paintings and engravings and other sources, and will contain detailed photographs of the

anatomy of "Eclipse" and the most famous of his descendants, which should prove interesting both to biologists and breeders. It is important that information should reach the authors before June 1 if possible, and all letters, manuscripts, prints, or pictures addressed to "Eclipse," c/o Mr. W. Heinemann, 21 Bedford Street, London, W.C., will be acknowledged before that date, and will be treated with the greatest care.

Mr. Henry S. Wellcome, of Snow Hill Buildings, E.C., is organising an exhibition in connection with the history of medicine, chemistry, pharmacy, and the allied sciences, and has issued a circular indicating the range of the proposed exhibition. The loan of any objects of interest is solicited; these will be insured and carriage paid both ways. The date of the proposed exhibition has not yet been definitely settled.

In the *Comptes rendus* of the Paris Academy of Sciences (April 2, p. 823) M. Lortet gives an account of an examination of the contents of four vases containing the viscera of King Rameses II., the Sesostris of the Greeks, who is believed to have died about 3164 years ago. Profs. Hugounenq, Renaut, and Rigaud were associated with M. Lortet in the examination, and three of the vases were surmised to contain the stomach, intestine, and liver of the great king preserved with soda and aromatic resinous substances, and enclosed in linen bandages. A fourth jar contained the heart of the monarch, hard and horn-like, but on microscopical examination showing the typical bundles of muscle fibres of cardiac muscle, crossing one another.

In the April number of the *Monthly Review*, Mr. Paul Uhlenhuth writes on the blood-relationship of man and apes, and describes how, by means of the precipitin test, various albuminous substances and the blood of different animals may be distinguished from one another. The test has also considerable medico-legal importance, and biologically may be employed to ascertain the relationship of various animals to one another. In this way it may be shown that the anthropoid apes are most nearly akin to man, while the lemurs are but distantly, if at all, related to him.

Some years ago Dr. A. Gallardo advanced a dynamical interpretation of the karyokinetic figures in cell division that was explained in Nature of November 13, 1902, by Prof. M. Hartog. Dr. Gallardo has somewhat modified his former theory, and applying the results obtained from a study of the properties of colloids, he postulates in a paper published in *Annales del Museo Nacional de Buenos Aires*, vol. xiii., a negative charge for the chromatin and a positive charge for the cytoplasm around the poles of the spindle. In proof of his theory the writer reproduces the figures obtained with special apparatus on a metallic plate forming one electrode in an electrolytic solution.

It is remarkable that, despite the numerous investigations during the last ten to twenty years into the coffee-leaf disease caused by species of Hemileia, the complete life-history of the fungus has not been worked out. Mr. G. Massee directs attention to the want of information concerning the æcidial stage in his revision of the genus published in the Kew Bulletin, No. 2, 1906. Four species, two of them recently determined by Mr. Massee, are described, and the probability of the æcidial stage is considered. In addition to an announcement regarding the publication, and a list of the contents of a volume on the "Wild Fauna and Flora of Kew Gardens," a supplementary list of fungi prepared by Mr. Massee is given, among which three species new to science are described and illustrated.

According to the *Pioneer Mail*, the Bombay Government has decided that arrangements should be made for the starting of experiments in the cultivation of rubber plants both in the southern and northern circles, and in the garden of economic botany which is about to be established in Bassein. In the northern circle Mr. Ryan has been requested to prepare and submit, under the direction of the conservator, a scheme for the plantation of the *Ficus elastica*, and for experiments with a view to ascertain the yield of rubber and its commercial value, and to suggest other rubber plants likely to show good results. At the Bassein garden Mr. Gammie has been asked to prepare a scheme of experiments on a smaller scale with numerous rubber-yielding plants with the object of ascertaining which are the most likely to succeed in the coast districts of the Bombay Presidency. For the southern circle orders have been given for the preparation of a scheme for experimental plantation, more particularly of Hevea, in one or more localities under the direction of the conservator.

Mr. O. F. Cook, in an article entitled "The Vital Fabric of Descent," published in the Proceedings of the Washington Academy of Sciences (vii., p. 301), urges that kinesis is the main factor in the evolution of organisms. "Kinesis is not a mysterious force or mechanism to be sought in reproductive cells; it is a general property of organisms, as gravitation is of matter. And of kinesis we know more than of gravitation. Two factors and two results are already obvious. The factors are heterism, or intra-specific diversity, and symbasis, or inter-breeding in a specific network of descent. . . ." "Natural selection neither originates species nor actuates their further development; progressive change would go on whether selection were active or not, and whether the environment were uniform or not. Nevertheless, selection conduces to adaptation, since by permitting changes in some directions and forbidding them in others, it deflects the specific motion. The workings of natural selection are adequately explained only by the kinetic theory."

In the *Zeitschrift* of the Berlin Gesellschaft für Erdkunde (1906, No. 3) appears the first part of an interesting historical paper on the measurement of geographical areas before the invention of the planimeter, by Dr. W. Schmiedeberg.

The new issue (vol. xix., part i.) of *Mitteilungen aus den deutschen Schutzgebieten* contains papers on the daily variation of temperature and pressure at Windhuk, German South-West Africa, and of temperature at Herbertshöhe, Bismarck Archipelago, by Dr. J. Hann. Dr. P. Heidke contributes a paper on the meteorology of German East Africa, dealing with the means for the years 1899 to 1902 from twenty-two stations.

The April number of the *Bollettino* of the Italian Geographical Society contains an extremely interesting paper, by Dr. Roberto Almagia, on the earliest Italian contribution to oceanography. The pamphlet described is the "Relatione del Mare" of Giovanni Botero, published in Rome in the year 1600, and it is remarkable that not only the main division of the subject into statical and dynamical sections, but the subdivisions of each of these into special parts, follow closely the method of treatment adopted in modern research.

We have received a reprint from the *Numismatic Chronicle* of a paper, by Sir John Evans, K.C.B., describing the silver medal or map of Sir Francis Drake, which commemorates the voyage round the world completed in 1580. Three, or at most four, examples of this medal are known, two of which are in the British Museum and one in Sir John Evans's collection. Sir John Evans agrees with Mr. Miller Christy that the silver map and that which is attached to the work of Peter Martyr, "De Orbe Novo" (Paris, 1587), are from the hand of the same engraver, about whom it is only known that the initials of his name were "F. G."

Two reports (Nos. 107 and 108) have been issued by the British Fire Prevention Committee containing particulars of experimental tests of the fire resistance of concrete floors. The two floors were practically identical in design, and were subjected to the same conditions. The results of the tests were, however, very different according to the concrete aggregate used. The one having Thames ballast concrete for the protection of its steel-work failed, whilst the other, with clinker concrete and coke breeze protection to the girders, remained intact. No independent fire tests on such a scale with floor areas measuring 15 feet by 22 feet have been previously carried out.

At the Institution of Civil Engineers an interesting paper on the resistance of iron and steel to reversals of direct stress was read by Dr. T. E. Stanton and Mr. L. Bairstow on April 10. The results of their experiments, which were carried out at the National Physical Laboratory, may be summarised as follows:—The superiority, in resistance to reversals of stress, of moderately high-carbon steels over low-carbon steels and wrought irons, which was discovered by Wöhler to exist when the rate of reversals was 60 per minute, still holds when this rate is increased to 800 per minute, although, according to Reynolds and Smith's experiments, this superiority no longer exists when the rate of reversals is in the neighbourhood of 2000 per minute. So far as comparisons can be made between the results of the authors' experiments and those of Wöhler and Sir Benjamin Baker, there is no marked reduction in resistance due to raising the rate of reversals to 800 per minute. Experiments in which the ratio of tension to compression varied from 1·4 to 0·72 indicated that between these limits the value of the maximum range of stress was practically independent of the actual values of the limiting stresses in tension and compression. The resistance of the materials in three typical cases of rapid reduction of area of the specimens has been determined. The failure of iron specimens due to the development of the slip-lines of Ewing and Rosenhain into cracks has been determined for the case of direct stress, and the failure of moderately high-carbon steel, due to the development of cracks in the ferritic areas of the structure, has also been established.

Messrs. Archibald Constable and Co., Ltd., will publish shortly a work on "Recent Advances in the Physiology of Digestion," by Prof. E. H. Starling, F.R.S.

Sir Martin Conway has written a history of Spitsbergen which the Cambridge University Press will shortly publish under the title of "No Man's Land."

The London Stereoscopic and Photographic Company, Ltd., has issued a new catalogue of photographic apparatus intended primarily for the use of amateurs. The list is attractively produced and conveniently arranged, and copies may be obtained post-free on application.

The Country Press, 19 Ball Street, Kensington, has published a series of twelve picture post-cards of the leaves of British trees and shrubs showing the exact venation in each case. These cards are intended for the use of children and others taking up nature-study; but it is to be hoped that teachers will prefer to direct the attention of their pupils to the actual leaves of plants, and to encourage the children to collect and study natural objects themselves rather than pictorial representations of them, however correct and artistic these may be.

OUR ASTRONOMICAL COLUMN.

Employment of Selenium Cells during Total Solar Eclipse.—During the total eclipse of August last, the observers at Tortosa made use of selenium cells for the double purpose of determining the variation in sunlight during the progress of the eclipse, and of ascertaining the exact moments of the beginning and end of totality.

As is generally known, the electrical conductivity of selenium increases on exposure to sunlight, being especially sensitive to the less refrangible end of the spectrum; therefore, by placing the cell in series with a battery and a delicate reflecting galvanometer, the amount of light falling on the selenium may be registered by registering the movements of the galvanometer beam of light.

Whilst the decrease of light, during an eclipse, is not *visible* until the eclipse is well advanced, the galvanometer needle at Tortosa was seen to move immediately after first contact, and for nearly an hour showed a uniformly increasing resistance.

Assuming that the light during totality was of the same quality as that obtaining at dawn, the results derived from the observations show that its brightness was about equal to that of the sky some thirty or forty-five minutes before sunrise.

The results obtained regarding the instants at which totality began and ended were very satisfactory, and it is suggested that, by placing similar equipments along the line of totality during future eclipses, far better results could be obtained than by the visual observations hitherto depended upon (*Astrophysical Journal*, No. 2, vol. xxiii.).

Catalogue of Pleiades Stars.—We have received from Dr. R. S. Dugan, of the Princeton (N.J.) Observatory, a copy of the inaugural dissertation presented by him for the doctorate of the Heidelberg University.

This publication contains the magnitudes and mean places (for 1900·0) of 359 stars of the Pleiades group. In addition to the catalogue, Dr. Dugan discusses the methods employed in measuring the plates and reducing the data thereby obtained. A chart of the group, on which the catalogue number of each star is shown, also accompanies the dissertation.

The Total Solar Eclipse of the Sun of January, 1907.—Among the numerous important papers communicated to the meeting of the Astronomical and Astrophysical Society of America, held at New York on December 28–30, 1905, there is one by Prof. David Todd which will probably be found to be of special interest to eclipse observers.

Prof. Todd and Mr. Baker have computed the essential data for ten possible stations, and have discussed the latter and the means of getting to them. It appears that the new railway across Russian territory will afford the greatest facilities for reaching the Turkestan stations, whilst observations will also be possible some 600 miles north-west of Peking. The complete discussion is to be published in the *American Journal of Science* (*Science*, No. 586, vol. xxiii., N.S.).

Observations of Nebulæ.—Since the year 1884 M. Bigourdan, of the Paris Observatory, has been assiduously employed in making a complete survey of nebulæ.

The results of this survey are to be published in five volumes, of which two (iv. and v.), dealing with the nebulæ situated between 14h. and 24h., have already appeared.

At the meeting of the Paris Academy of Sciences held on March 19, M. Bigourdan presented the second part of

vol. i., including the measures of nebulæ situated between oh. and 2h. of right ascension. The first part of this volume will contain the introduction, and will include a full description of the instruments and methods employed in the research.

Vol. ii., including the section 2h.–9h., is to appear soon, and will be followed by vol. iii., giving the results for the region 9h.–14h. (*Comptes rendus*, No. 12).

A LARGE PHOTOGRAPHIC NEBULA IN SCORPIO.—On examining the photographs obtained during his sojourn at Mount Wilson last year, Prof. Barnard found that an immense region near to π and δ Scorpii is occupied by a large nebula which is comparable in size, and in the peculiarities of its several branches, with the great nebula in Orion and the extended nebulosity of the Pleiades.

A short description of this nebula, together with a splendid reproduction of a photograph of it, taken with the 10-inch Brashear lens of the Bruce doublet, is given in No. 2, vol. xxiii., of the *Astrophysical Journal*.

The nebula extends some $4\frac{1}{2}°$ or $5°$ in a north and south direction, and its brightest portion lies about $\frac{1}{2}°$ to the south of π Scorpii.

A striking fact in connection with this object is that all the larger stars connected with it are, as might be expected, of the Orion type.

Prof. Barnard thinks that the branching, straggling character of this and similar nebulæ tends to discredit the accepted form of the nebular theory of stellar evolution, and doubts whether that theory would have ever been constructed if, at the time, our present knowledge of the appearance of nebulæ, as shown by photography, had been available.

CANADIAN TIDES.

A PAPER on tide levels and datum planes on the Pacific Coast of Canada was read recently by Mr. W. Bell Dawson, the engineer in charge of the tidal survey, at the meeting of the Canadian Society of Civil Engineers. The survey of the Canadian waters on the Atlantic side has been in progress now for some years under Mr. Dawson's charge, and has so far advanced that permanent tide gauges have been fixed at several representative parts of the coast, and sufficient tidal observations obtained to enable the Marine Department to issue tide tables for most of the principal ports. The survey has now been extended to the Pacific Coast.

In the paper under notice the bench marks and data used by the Admiralty, the Hudson's Bay Company, and the town authorities on the coast have been connected up by levelling, and the bench marks at Victoria, Esquimault, Vancouver, and other tidal stations referred to one common standard. These levels are given in the pamphlet. The importance of publishing such results is emphasised by the fact that the bench marks of former surveys are now to a great extent useless, because they were never made public, and the level books containing the records of these surveys have been destroyed by fire, and so a large amount of good work has been rendered useless, and subsequent trouble and expense caused.

The tides on the Pacific Coast are peculiar, the leading feature being a pronounced diurnal inequality which accords with the declination of the moon, and is subject to an annual variation with the change in the declination of the sun; also there is an unusually large solar effect relatively to the lunar, especially in the northern part. In some parts of the coast during the greater part of the day there is a long stand or only slight fluctuation near high-water level, with a sharp, short drop to the lower low water which occurs once in the day. Owing to this diurnal inequality the two highest and lowest points in the tide curve for the month may be as much as five days before or after the full and new moon. While the tides on the Atlantic side of Canada follow the phases of the moon, and accordingly the alternations of spring and neap tides are the dominant features, the tides on the Pacific side may be described as declination tides.

The careful study of the tides and of the mean sea-level appears to indicate that this coast is rising at a rate as great as 1 or 2 feet in the century.

THE INTESTINAL TRACT OF MAMMALS.

IN a memoir "On the Intestinal Tract of Mammals" (Trans. Zool. Soc. of London, xvii., part v., December, 1905, pp. 437–536), Dr. Chalmers Mitchell extends to mammals the line of investigation which has already, in his hands, yielded results of great interest when applied to birds, namely, the systematic study of the pattern and arrangement taken by the folds and coils of the intestinal tract. With this object, the author describes the pattern of the intestinal coils in a great number of mammals dissected by him, representing examples of each of the principal subdivisions of the entire class. The descriptions are supplemented by an excellent series of text-figures, which show the arrangements in a semi-diagrammatic, but clear and accurate, manner. In the case of mammals of which the author has not been able to procure specimens for dissection, he quotes from the existing descriptions of other authors such details as apply to the problems which are the object of his investigation. Thus the memoir before us gives an account, which is practically complete, of what may be called the general morphology of the mammalian intestinal tract, that is to say, of that portion of the gut comprised between the stomach and the anus. From his investigations the author arrives at a number of interesting conclusions, of which only a few can be mentioned in the limits of this article.

Starting from an ancestral type of vertebrate, in which the alimentary canal ran a straight course through the body, suspended by a mesentery from the dorsal wall of the body-cavity, the gut becomes thrown into a series of folds as the result of a process of growth, whereby it becomes longer than the straight length between its extreme points. The process of elongation can be traced both phylogenetically, by a comparison of different vertebrate types, and ontogenetically, in the development of any given species. The more or less complicated folding of the gut which results involves the dorsal mesentery, and also the blood-vessels draining from the different parts of the gut, which tend to take short circuits between portions of the gut approximated to each other by the process of folding.

The intestinal tract, in both birds and mammals, is divided into two regions, anterior and posterior, by the outgrowth at a certain point of a cæcum or pair of cæca. Probably in all cases a pair of cæca were primitively present, as is usually the case in birds. In mammals, as a general rule, a single cæcum is formed, but in some cases two complete cæca, or a rudiment of a second in addition to the usual one, still occur. In a few cases, however, all trace of a cæcum has disappeared entirely. The intestinal tract anterior to the cæcum is divisible into two regions, the duodenum and the small intestine, or "Meckel's tract," as the author proposes to call it. The latter represents only a very short portion of the primitive straight gut, not more than two or three body-somites; but in nearly all birds and mammals it becomes the longest portion of the gut, growing out to form the greater part of what is known as the "pendant loop" in mammalian embryology, and is the chief absorbing portion of the gut. The intestinal tract behind the cæcum may be called the hind-gut, and corresponds to a much larger portion of the primitive straight alimentary canal than the duodenum and Meckel's tract together. In birds the hind-gut is relatively very short. In mammals, however, it is always long, sometimes extremely so, and becomes divided into two regions, the colon and the rectum. The colon is often greatly lengthened, and thrown into loops or coils. The rectum may also be considerably lengthened, but, as a rule, it is not very much longer than the portion of the primitive straight gut which it represents.

In certain groups of mammals a very primitive type of intestinal tract is still found. As the author points out, however, likenesses which are due to the common possession of primitive features, once possessed by the whole group, cannot be regarded as evidence of near relationship. Equally useless for proof of affinity are resemblances due to the loss or reduction of parts that were once the property of the ancestral stock. Clues to affinity must rather be sought in resemblances depending on definite anatomical peculiarities that are new acquisitions, and the more

complex these structures, the more convincing the evidence they furnish, since it then becomes so much the less probable that the same anatomical device should have been produced twice than that it should have been acquired once only. In the Artiodactyla, for example, "a definite case of an anatomical peculiarity, so well marked and complex as to be a safe guide to affinity," is seen in the elongation and spiral coiling of the proximal portion of the colon. The Perissodactyla and rodents supply other examples of evolution along a definite radius from the ancestral centre. From his investigations the author deduces inferences of importance for the general theory of evolution, especially as regards the limitation of the possible range of variation of organs in any set of animals which have once come to occupy a particular radius. Further changes and elaborations are then restricted by the past history, that is to say, by the limited material which it has furnished for further specialisation. In this way a simple explanation is given for the definite grooves, recognised by many writers, along which the specialisation of organisms must necessarily move, without having recourse to the assumption of any mysterious directive forces. E. A. M.

SCIENTIFIC REPORTS OF THE LOCAL GOVERNMENT BOARD.[1]

THE first half of the volume under notice is devoted to the medical officer's report, statistical data, and details of various inspections and inquiries by the Board's inspectors. The second half contains reports of the auxiliary scientific investigations carried out for the Board. The first of these is a memorandum by Dr. Theodore Thomson on rats and ship-borne plague. The conclusion arrived at is that "the part played by the rat in transmission of plague to man, although real, falls far short of the importance which has generally been attributed to it." This may be true, but in view of the predominant part played by the rat in the dissemination of plague in the various Sydney epidemics, it is to be hoped that the campaign against this rodent will in no way be relaxed.

Bearing on the same subject, Drs. Haldane and Wade report on methods of rat destruction and disinfection on ship-board. In this especial attention is directed to the Clayton process, in which sulphur is burned at a high temperature, and air charged with the products of its combustion is pumped into the ship's hold. The gas is rapidly fatal to rats and other vermin, and is germicidal to non-sporing microbes, but it does not penetrate a loaded hold well, and has a deleterious action on certain articles. On the whole, however, it seems to be the best method to employ for rat destruction. Dr. Klein details further experiments on the two types, virulent human and less virulent rat, of the plague bacillus differentiated by him and described in a previous report. Dr. Klein also records some interesting observations on the influence of symbiosis on the virulence of microbes.

An important paper on the differentiation of various streptococci and staphylococci is contributed by Dr. M. H. Gordon. Hitherto the differences exhibited by the members of these classes of micro-organisms, particularly the streptococci, have been slight and indefinite, but by making use of culture media containing various mono-, di-, tri-, and poly-saccharides and glucosides, important differential characters are obtainable. Dr. Sidney Martin has continued his studies on the toxic action of microbes, dealing in the present volume with that of the *Proteus vulgaris*. The results, however, in this case are somewhat indefinite, the toxic reaction being mainly evinced by the development of agglutinin in the blood. Dr. Houston gives a detailed report of the bacteriological examination of normal human dejecta, and of the intestinal contents of sea-fowl and of fish. All gulls contained typical *B. coli* in their excrement in enormous numbers, but guillemots did not contain *B. coli* of any sort. As regards fish, those obtained "from a source seemingly above all suspicion of objectionable contamination, may contain sometimes apparently typical *B. coli* in their interior; in the great majority of cases the results were either wholly negative or the microbes that were isolated proved to be atypical in character."

Dr. Alan Green contributes further observations on chloroformed calf vaccine which prove that the quality of the lymph prepared by this method is of a high order.

The above brief review shows that this report contains matter of the greatest interest and importance which should be studied by all bacteriologists and by those to whom the care of the public health is entrusted.

INFRA-RED SPECTRA.[1]

THE record of an enormous amount of work on the absorption spectra of organic compounds and emission spectra of various metals and gases in the infra-red region is given in the volume under notice. The investigations were commenced whilst the author was a graduate student at Cornell University, and completed under the auspices of the Carnegie Institution of Washington.

Even to summarise the mass of valuable information contained would exceed the limits of our present space, but it may be said at once that, to workers along similar and related lines, these results, and the descriptions of the apparatus and methods whereby they were obtained, are indispensable.

Part i. occupies nearly seven-eighths of the whole volume, and deals with the absorption spectra of 131 organic compounds up to 15 μ. As is pointed out in the very complete historical review, all previous workers in this subject have abandoned the investigation at 7 μ for the alcohols and 10 μ for some few other compounds.

The description of the apparatus and methods is exhaustive and invaluable. From 0·8 μ to 2·5 μ a quartz prism was employed, beyond that, and up to 15 μ, one made of rock-salt. The source of the radiations was a Nernst lamp "heater," which gives a spectrum of which the energy curve is smooth and continuous. A reflecting spectrometer of 35 cm. focal length was employed for the explorations of the spectrum up to 15 μ, and a considerable portion of the work up to 7·5 μ was repeated with a spectrometer of 1 m. focal length.

The distribution of the energy in each spectrum was determined by means of a radiometer similar to that devised by Nicholls, but with some modifications.

The principal reasons for this investigation were the determination of the influence of molecular weight upon absorption spectra, and also the effect of molecular structure. The results show that in different compounds each of these causes in turn acts separately, whilst in other compounds the absorption is produced by the combined effect.

In recording the quartz-prism results the author deals separately with each absorption band in the nineteen compounds investigated, whilst in the other results the compounds are treated separately, notes being made of the chemical structure and properties of each substance where necessary.

Numerous tables set out the numerical results in various forms, whilst 140 full-page *transmission* curves show them graphically. In addition to these the author has written seven brief appendices dealing with side-issues in connection with the apparatus and the investigation and its results.

In part ii. Mr. Coblentz deals with the infra-red emission spectra of various metals, metallic chlorides (alkalies), and gases. The metals were employed as the poles for the arc producing the radiations, whilst the chlorides were volatilised on carbon arcs. The apparatus was very similar to that described in part i., except for a few modifications rendered necessary by the greater intensity and unsteadiness of the radiations.

With the metals, a black-body spectrum due to the oxides, and sufficiently strong to obliterate any emission lines which might be present, was found, and in the alkali chloride spectra no lines were discovered beyond 2 μ. Of the gases investigated—in vacuum tubes—N was found to be the only one having strong emission lines in its infra-red spectrum. CO_2, CO, and the vapour of C_2H_5HO were

[1] "Investigations of Infra Red Spectra." By William W. Coblentz. Pp. vi+331. (Washington, D.C.: The Carnegie Institution, 1905.)

found to exhibit a very strong emission band at 475μ. The emission spectrum of C_2H_5OH shows that a vapour in a vacuum tube can emit a continuous spectrum.

Ångström's conclusions—deduced from the fact that the total radiation *increases*, while the luminous radiation *decreases*, with increase of pressure in the gas—that there are two kinds of radiation present during the electrical discharge are found to be in close agreement with the observed facts. These different discharges were named "regular" and "irregular" (*i.e.* luminescence) by the previous observer. An interesting theoretical discussion of the action of pressure in this connection is given in the volume.

W. E. R.

DISEASES OF VINES.[1]

TWO parts of the *Annales de l'Institut Central Ampélologique Royal Hongrois*, devoted to two of the vine diseases, have lately reached us.

In one of these parts (part iii.) an account is given of the little known disease caused by the attacks of *Phyllosticta Bizzozeriana*. The disease was first noticed in the year 1900, and it has been kept under observation since then, with the result that its spread has been traced in some detail. The symptoms are somewhat similar to those of the dreaded "black-rot," but it does not appear as if it will prove so dangerous a parasite. In addition to a brief life-history of the fungus, illustrated by an excellent plate, a useful compendium of the species of Phyllosticta occurring on the vine is given.

Part iv. contains an unusually complete account of the "grey-rot" caused by *Botrytis cinerea*. This is one of the parasites of the vine which the cultivator most dreads. All aërial parts of the host-plant are attacked indiscriminately, and quickly become covered with a greyish or brown mould, which produces enormous quantities of ashy-grey spores. This stage is succeeded by the formation of small black sclerotia in the diseased tissues of the stems, leaves, and fruits. Naturally the fungus has been investigated time after time, but the researches of Istvanffi, published in this volume, have added a number of fresh facts to our knowledge of its life-history. In the first place, a series of laboratory investigations was made with the object of determining the conditions under which the fungus brought about the infection of the host-plant. The optimum temperature for the germination of the spores proved to be 25° C., whilst the spores were killed by exposure to a temperature of 38° C. to 41° C. The effects of drying the spores were then investigated. One day's drying over sulphuric acid at laboratory temperatures, either in light or darkness, was sufficient to kill 75 per cent. of the spores, and desiccation for thirty-six days was fatal to all of them. Spores previously germinated and exposed to this treatment suffered still more severely. The results of freezing were again seriously to diminish their germinating capacity.

The action of a number of the commoner fungicides on spores was then examined, with interesting results. Thus a 1 per cent. solution of Bordeaux mixture only prevented the germination of some 60 per cent., and a 10 per cent. solution about 10 per cent. Spores which were allowed to dry after soaking in Bordeaux mixture all failed to germinate. Others sown in drops on the foliage of the host-plant not only germinated, but infected the tissues below them. On examining the action of the constituents of this mixture, lime water proved to be singularly efficacious in preventing germination.

In the majority of these experiments the spores of Monilia and of Coniothyrium were exposed to the same conditions, with results, on the whole, similar to those already quoted. At the same time, the life-history of the fungus was traced in detail. Istvanffi succeeded in germinating the sclerotia, and has settled the point once for all that they do give rise to the apothecia of *Sclerotinia fuckeliana*. So many observers have failed to obtain this ascigerous stage that it is well to have this definite statement. The sclerotia retain their germinating capacity for at least twenty-one months. Another interesting point brought out in the course of this research is that the well known adpressoria of the fungus are the early stages in the development of the sclerotia. In addition to the microconidia observed by Brefeld and others, Istvanffi records the production of an oidial stage.

For further details, and for methods to be adopted for checking the spread of this pest, the original must be consulted. It is full of points of interest to the student of plant pathology, and makes one regret more and more that this country possesses no institute similar to the Central Ampélologique Royal Hongrois, where the pressing problems of plant disease can be adequately examined. Here we have to trust to the private individual for what investigations are made, and he all too rarely has opportunities to make them on the comprehensive scale possible at such an institution.

EARTHQUAKE ORIGINS.

AMONG the most interesting and important of the new ideas, which have been introduced into seismology, in late years, must be classed Major E. G. Harboe's notion of the nature of earthquake origins. Originally treated as a point, the focus of an earthquake has long been recognised as an area, but we are still in the habit of regarding it as restricted in size and small in comparison with the dimensions of the area over which the earthquake is felt. On this hypothesis the decrease in violence is correlated with increase in distance, and due to a gradual diminution of intensity as the disturbance travels from its origin; according to Major Harboe's conception, the focus of an earthquake is no longer restricted in size, but ramifies, with a varying degree of initial violence, over nearly the whole of the seismic area.

On the generally accepted hypothesis the coseismal lines should more or less correspond with the isoseismal, a decrease in violence being accompanied by an increase of time interval, but such is far from being the case, and we have been in the habit of attributing the irregularities to errors of observation; Major Harboe has now shown that another explanation is possible, and that the irregularities in recorded times almost disappear if his hypothesis of the nature of the origin is adopted. From the discussion of the records of earthquakes he reaches the conclusion that the true rate of propagation of the sensible shock is about 0·4 kilometre per second, the higher velocities obtained by other investigators being compounded of the rate of propagation of the disturbance along the origin, and that of the wave-motion set up by this disturbance.

This rate of propagation is that of the sensible shock, which can be felt by human beings, and not that of the large waves recorded by seismographs outside the seismic area proper; the latter, the rate of propagation of which is about 3 kilometres per second, are regarded as different in character, and propagated in the consolidated rock at some little depth below the surface, the sensible shock being due to quite superficial waves propagated through the more fissured and less coherent surface rocks.

One of the weightiest of the objections to this hypothesis was the value of $3{\cdot}28 \pm 0{\cdot}05$ km. sec. obtained by Profs. Sekiya and Omori in 1902 from the seismic triangulation started by Prof. Milne in 1884. This is dealt with in vol. viii., part iii., of Gerland's *Beitrage zur Geophysik*, where Major Harboe remarks that, in spite of the long period over which the observations extended, only four earthquakes seem to have given usable records from all the stations, three earthquakes at three stations, and one at two stations. Taking two of these earthquakes, for which records from a number of meteorological observatories have been published, he finds that the velocity and direction of propagation, deduced from the triangulation, lead to most discordant results at other stations, irregularities which disappear if a branch of the origin is supposed to have traversed the field of triangulation and the disturbance to have spread outwards to the stations.

Whether the hypothesis stands the test of future investigation or not, it seems to explain many previously inexplicable anomalies, apart from those of time. It appears to work out satisfactorily in the case of those earthquakes by which Major Harboe has attempted to test

it, but the only true testing must be left to investigators of the future, for it is to be feared that in the past seismologists have been inclined to reject, as bad, all records of time which failed to fit in with their preconceived ideas of the direction of propagation of the shock, though they might have fitted in with a less simple, though possibly truer, conception of the form and extent of the earthquake origin.

R. D. Oldham.

CURRENTS IN THE STRAITS OF MESSINA.

For our knowledge of the physical conditions at the bottom of the sea we are very largely beholden to the enterprise of submarine cable companies; indeed, it is difficult to imagine a more thoroughly satisfactory method of survey than that employed by them. Duties connected with the maintenance of cables have led to the discovery of details in the configuration of submarine gullies, of fresh-water outlets beneath the sea, and of alterations in the bed of the ocean itself, which would otherwise have eluded observation. Prof. Platania, of the Istituto Nautico of Catania, has directed attention to another rather surprising fact, namely, that in the Straits of Messina there are deep-water currents of sufficient velocity to cause the interruption of the cables joining Sicily with the mainland ("I cavi telegrafici e le correnti sottomarine nello stretto di Messina," reprinted from the *Atti della R. Accademia Peloritana*, vol. xx.). The period under observation covers the last forty years, during which time there have been twenty-six interruptions; neglecting two, nineteen occurred between November and April, and five between May and October. The strong currents cause a continual attrition by sand and pebbles. The rocks on the sea bottom are swept free of mud and sand, and their rough surfaces, thus exposed, have worn out the cables lying upon them. In one case a cable seems to have been corroded by a sulphurous spring. The surface currents attain a speed of five miles an hour. They have always been a danger to navigation, and the wrecks of two large vessels which were lying last summer upon the Sicilian shore show that Scylla and Charybdis have lost none of their power. The existence of correlated strong deep-water currents had been suspected. Biologists have long been attracted to Messina by the plentiful harvest of deep-sea animals which are occasionally brought up to the surface by a vast turmoil of waters, thus affording almost unique opportunities. M. Thoulet and others have repeated the classical experiments of our countryman, Captain Richard Bolland, made in 1675 in the Straits of Gibraltar, and have demonstrated the existence, at twenty fathoms, of an undercurrent flowing in a contrary direction to that on the surface, but these currents have not yet been as systematically studied as the importance of the subject demands. The tides, as is frequently the case in narrow straits, as, for instance, inside the Isle of Wight, are doubled.

A PERIODICAL FOR PALÆONTOLOGISTS.

This new venture in scientific literature,[1] which is to appear quarterly, and leads off with a double number, will be warmly welcomed by all palæontologists, for since the "Annales des Sciences Géologiques" ceased to exist, there has been no accredited journal for palæontology in France. The "Annales des Sciences Naturelles: Zoologie," it is true, has on occasion offered the hospitality of its pages, but the whole of its space is not too great for the living subject.

Material enough and to spare lies ready to hand at the Paris Museum in collections from all parts of France and its colonies, while it is further intended to carry on D'Orbigny's incompleted tasks begun in his "Paleontologie Française" and "Prodrome de Paléontologie stratigraphique universelle." The publication of illustrations of the yet unfigured types of the latter work, with reprints of the author's diagnoses, accompanied by notes and explanations, an undertaking of great merit, is begun in this first part.

As regards guiding principles, the editor, while not wishing in any way to dictate to his contributors, gently suggests in his introduction that he has preferences. On the one hand, he seeks memoirs on stratigraphical or purely systematic palæontology, in which the principal object will not be the multiplication of genera and species, holding as he does that *mieux valent des choses sans noms que des noms sans choses.* On the other, he inclines to papers having a philosophic bearing.

With his former predilection all must be in accord, while of the latter, the very first paper, one by the veteran Albert Gaudry, "Fossiles de Patagonie. Les attitudes de quelques Animaux," is an excellent example, where "attitudes" is used to express the comparative bearing, gait, and appearance, and not posture alone. The author points out that in Tertiary times in Patagonia Plantigrades and Rectigrades predominated over Digitigrades.

The editor and M. A. Thevenin give the first instalment of a series of memoirs on the palæontology of Madagascar, in which they deal with the molluscan fauna from newly discovered Upper Cretaceous beds on the eastern side of the island. Some of the species enumerated are identical with those found by the Rev. R. Baron in the northern and north-western districts, that were described by Mr. R. B. Newton in the Quart. Journ. Geol. Soc. for 1889 and 1895, a fact to which, however, allusion is not made. This fauna presents considerable analogy with that which lived during the same epoch in India.

The second contribution to the same series, by M. Douville, treats of some nummulitic beds in Madagascar.

M. Boule adds a memoir on "Les grands Chats des Cavernes," principally the lion, that takes the form of a popular review of current knowledge on the subject.

The part concludes with the opening portion of the descriptions and figures of D'Orbigny's types already referred to.

Altogether there are 100 pages of text, with nine phototype plates, besides abundant illustrations in the text, all the figures being most excellent, and veritable works of art.

There is, indeed, but one objection to raise, and that is against the adoption of dual pagination, each paper having its distinct pagination in addition to that of the volume, because the disadvantages of this system for purposes of citation far outweigh any possible benefits.

It is to be hoped that the glossy surfaced paper selected, so suitable for modern text illustrations, though not for type of the face employed, is not of that perishable description which we have been lately warned will deprive future generations of the fruits of our intellectual labours.

B. B. W.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—The special board for mathematics has put forward new proposals, both with regard to the mathematical tripos and the mechanical sciences tripos, which involve far-reaching changes. The first-named report points out that in the opinion of the special board the existing mathematical tripos is unsatisfactory as an examination. The special board proposes to substitute for the present part i. a new part i., which may be taken by a student either at the end of his first or second year. Part i. will not qualify for a degree without further examination. It is hoped that this part will be taken by many who propose to proceed later to study engineering or natural sciences. The board further proposes that for the existing part ii. a new part ii. be established, which must be taken at the end of the third year. The position of senior wrangler is abolished, but the class list of each part will contain three classes, the names in each class being arranged alphabetically. Schedules are published for each of the proposed new parts.

With regard to the report of the mechanical sciences tripos, the special board of mathematics suggests that part ii. of the tripos should be abolished, and it is proposed to modify part i. by the inclusion of a number of

papers on questions of greater difficulty or of wider range than the average of those now set. The other papers of this part are, however, to be made easier than the present average. The board hopes to include a paper on chemistry in the future. It is also considered to be desirable that the examiners should be empowered to take into consideration the laboratory and drawing-office work done by the student during his course; but perhaps the most important of the recommendations is that every candidate for the mechanical sciences tripos, unless he has obtained honours in one of the honours examinations of the University, must pass a qualifying examination in elementary mathematics and mechanics, which will be held twice a year.

The special board for biology and geology has renominated Mr. F. A. Potts, of Trinity Hall, to use the University table at Naples for four months from April 1. Applications for the use of this table and for that at the Marine Biological Association's laboratory at Plymouth should be sent in to the chairman of the special board (Prof. Langley) on or before May 24.

Dr. Haddon is giving a special course of lectures on magic and savage religion on Mondays during this term.

PROF. FRIEDRICH CZAPEK, of the Prague Technical High School, has been appointed professor of botany in Czernowitz University. Prof. Armin Tschermak, of the University of Halle, has been appointed professor of physiology and medical physics in the Veterinary High School, Vienna.

IT is announced by *Science* that Adelbert College, Western Reserve University, has received 30,000*l.* from the grandchildren of Mr. Joseph Perkins, formerly a trustee of the college. The money is to be used for a department of sociology and a chemical laboratory.

ON Commemoration Day at Glasgow University on April 18 the honorary degree of Doctor of Laws was conferred upon Mr. James S. Dixon, founder of the lectureship of mining in the University, and Mr. R. E. Froude, superintendent of the Admiralty experimental works at Haslar.

ALTHOUGH we are far behind other nations in governmental recognition of the claims of anthropology, the universities, the older ones leading the way, are following their Continental sisters in making it a subject of systematic study by providing courses of instruction and establishing diplomas and other distinctions. The Oxford committee for anthropology has just issued the regulations for the diploma and the list of lectures for the next two terms. It is pointed out by the committee that not only members of the university, especially those whose work will bring them in contact with native tribes, will benefit from the newly-established course of study, but also those already in contact with native races who feel the need of extending their anthropological knowledge during their "long leave." The schedule of lectures shows that although no provision can yet be made for systematic instruction covering the whole of the very wide field in even a summary manner, students who present themselves are sure of finding helpful and stimulating teaching in all the more important branches of the subject: the chief omission at present is the failure to include social organisation, usually a crux for missionaries and the untrained generally, among subjects on which aid may be sought. The secretary of the committee is Mr. J. L. Myres, Christ Church, from whom all information may be obtained.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 1.—"A Further Communication on the Specificity and Action *in vitro* of Gastrotoxin." By Dr. Charles **Bolton**.

An analysis in the test-tube of the gastric cytotoxin obtained by injecting the rabbit with guinea-pig's stomach cells has shown that it is a complex body. After a single injection there is a great increase in the hæmolysin normally occurring in the rabbit's blood, and after further injections an artificial hæmolysin makes its appearance. The artificial hæmolysin is distinguished from the natural hæmolysin, because the former can be complemented by guinea-pig's normal blood serum, whereas the latter cannot. There is also present in the immune serum a substance which agglutinates the red blood corpuscles. Closely associated with the appearance of this artificial hæmolytic immune body is that of an agglutinin which acts upon the gastric granules, and also that of a precipitin which acts upon the soluble proteids of the gastric cells. By repeating the injections these substances are found to be present in the blood for several months. Whether they are one and the same or distinct bodies has not yet been proved. After several injections, and not less than about five weeks from the first, a further substance appears in the blood, which possesses an action upon the intact gastric cells. In spite of repeated injections this substance disappears from the blood in about four months. It is probably of the same nature as a hæmolysin, but this point requires proof.

The hæmolytic factor is only active against blood. The actions of the agglutinin and precipitin are not confined to the constituents of the gastric cells, but extend to other proteids of the body. Whether there are separate agglutinins and precipitins for different proteids, or whether the same substances act upon all proteids, has not been determined; at all events, if the same bodies are concerned in all cases, their action upon the proteids of the stomach cells is probably greater than that upon other proteids. Whether the gastrolysin itself is truly specific remains to be proved.

The few experiments that have been undertaken in the case of the human stomach indicate that the human gastric cytotoxin is identical in constitution with that of the lower animals.

February 8.—"Explosions of Coal-gas and Air." By Prof. Bertram **Hopkinson**.

The explosion of homogeneous mixtures of coal-gas and air at atmospheric pressure and temperature is investigated by means of platinum resistance thermometers placed at various points in the explosion vessel. The vessel is of dumpy cylindrical form and 0·2 cubic feet capacity, and the mixture is fired by an electric spark at the centre. Each thermometer consists of a loop of bare platinum wire about 5 centimetres long and 1/1000th inch diameter, which is placed in series with a battery of constant potential and a reflecting galvanometer, of short periodic time, the deflection of which is recorded photographically on a revolving drum. On the same drum the pressure of the gas is recorded. The arrival of the flame at any wire is marked by a sharp rise in its resistance, and the rate of rise, when corrected for the time lag of the wire, gives a measure of the velocity with which the gases about it combine. It is found that with a mixture consisting of one volume of gas and nine of air the flame spreads from the spark in a somewhat irregular manner, but at a rate of roughly 150 centimetres per second. A thermometer placed near the spark shows a sudden rise of temperature to about 1200° C., after which the temperature remains nearly constant until the flame approaches the walls of the vessel. With the rapid rise of pressure which then occurs the adiabatic compression of the burned gas at the centre causes the temperature there to rise to about 1900° C., with the result that the wire of the thermometer generally melts. At a point near the walls the gas is compressed to near the maximum pressure before ignition, and the temperature consequently rises suddenly to 1200° C. or 1300° C., and as there is little subsequent compression there is not much further rise of temperature. Thus, in consequence of the different treatment of the gas at different points in the vessel, differences of temperature of 500° C. exist in the gas at maximum pressure after an explosion of this kind. That such differences must necessarily exist after an explosion even in a vessel impervious to heat does not appear to have been noticed hitherto. These differences are rapidly obliterated by convection currents, but their magnitude at the moment of maximum pressure is such as to make it impossible to obtain an accurate estimate of the specific heat from the pressure record after the manner of Messrs. Mallard and Le Chatelier. The work of these experimenters is not, however, open to the chief objection that has hitherto been urged against it, viz. that combustion was incomplete when they measured the specific heat. The experiments here described show that the combustion at any point is prac-

tically finished 1/40th of a second after it begins, and that 1/30th of a second after the attainment of maximum pressure the gas in the vessel may be regarded as a mixture of CO_2, steam, and inert gases in chemical equilibrium.

The pressure of the ignited gas at the centre of the vessel is increased during the spread of the flame from one atmosphere to six. During this time it loses no heat, and the rise of temperature observed is from 1200° C. to 1900° C. It follows that between these limits of temperature the average value of γ for these gases is 1·25.

With a weaker mixture containing one volume of gas and twelve of air the spread of the flame is very much slower, about $2\frac{1}{2}$ seconds elapsing before all the gas is burned. Owing to the slow propagation of the flame, convection currents play an important part during the process of ignition; the burned gases rise to the top of the vessel, and the last portion of gas to be ignited is not close to the wall, but immediately under the spark, and a short distance from it; but though the flame is propagated very slowly, the combustion of any given portion of gas, when once started, proceeds almost as rapidly as in the stronger mixture. There is no "after-burning" in the sense of the slow completion of a reaction already begun. Within 1/10th of a second before the time of maximum pressure some gas is still unburnt; within 1/10th of a second after all the gas is completely burned, and the mixture everywhere in chemical equilibrium.

Incidentally, the difference of temperature between a fine wire immersed in the gas and the temperature of the gas is determined by comparing the temperatures of two wires, one having double the diameter of the other, placed close together in the same explosion. The error due to radiation is thus found, and it is shown that if a wire 1/500th of an inch in diameter is getting hotter at the rate of 1300° C. per second, then it must be 200° C. colder than the gas surrounding it. The results are used to find the actual temperature of the gas from that of a wire 1/1000th of an inch diameter immersed in it, and the conclusion is drawn that the temperatures in a gas-engine cylinder cannot be obtained by the use of a wire thicker than this, except by applying corrections amounting to several hundred degrees centigrade.

The bearing of the results on the question of "after-burning" in the gas engine is discussed, and it is shown that the high specific heat of the products of combustion, together with some loss of heat during the passage of the flame through the compression space, accounts for all the peculiarities of the gas-engine diagram. The form of diagram obtained with weak mixtures is due simply to the very slow propagation of the flame, and not to any delay in the attainment of chemical equilibrium at a point which the flame has already reached.

March 15.—"A Discussion of Atmospheric Electric Potential Results at Kew, from selected Days during the Seven Years 1898 to 1904." By Dr. C. **Chree**, F.R.S.

The paper contains an analysis of atmospheric electricity results at Kew on selected fine-weather days—usually ten a month—from 1898 to 1904.

All days were excluded when rain fell or negative potential was recorded. All data are given in absolute measure (volts per metre). The diurnal inequalities for individual months and the year are represented by curves. These all show two distinct daily maxima and minima. The minima always occur near 4 a.m. and 2 p.m. The times of the maxima are more variable, the day interval between the two being longer in summer than in winter.

The highest mean potential gradient occurs in December. Whilst the amplitude of diurnal inequality is greatest in mid-winter, the ratio in which it stands to the mean daily value is then least. The diurnal inequalities for the several months are analysed in 4-wave Fourier series. The 12-hour term is, in general, the most important; the changes in its amplitude and phase angle throughout the year are comparatively small. The 24-hour term is much larger in the winter than in the summer months, and its phase angle varies greatly. Attention is also given to the phenomena of individual days. The difference between the highest and lowest hourly values averages two and a half times the amplitude of the regular diurnal inequality, and is fully larger than the mean value for the day.

Of various meteorological elements temperature is found to have much the most marked influence, high mean potential and large diurnal range of potential being associated with low temperature in every month of the year, except the hottest (July).

An appendix compares the diurnal inequalities of potential and barometric pressure. Diurnal inequalities were got out for each month of the year for the barometric pressure at Kew for an 11-year period. The similarity between the diurnal inequalities of the two elements is found to be confined to the 12-hour terms; the 24-hour terms present diametrically opposed phenomena in the two cases. The afternoon minimum and evening maximum of potential are in every month notably in advance of those of barometric pressure. If any relationship of cause and effect exists between the *regular* diurnal changes in the two elements, the pressure change would seem to be the effect, the potential change the cause.

Geological Society, April 4.—Mr. R. S. Herries, vice-president, in the chair.—A case of unconformity and thrust in the Coal-measures of Northumberland: Prof. G. A. L. **Lebour** and Dr. J. A. **Smythe**. The sections described occur on the coast north of the Tyne, near Whitley Sands, between Table Rocks and Briar-Dene Burn. The base of the "Table-Rocks Sandstone" is found to rest unconformably upon a series of alternating shales and sandstones, among which is a well-marked band of clay-ironstone crowded with *Carbonicola acuta*, one of those "mussel-bands" which are found to be perhaps the most remarkably persistent strata in the north of England Carboniferous rocks.—The Carboniferous succession below the Coal-measures in North Shropshire, Denbighshire, and Flintshire: Dr. Wheelton **Hind** and J. T. **Stobbs**. This paper opens with a critical account of previous research among the Carboniferous rocks of North Wales. Then follows a detailed account of the various beds, exposed in numerous quarries worked for road-metal, iron manufacture, lime, cement, chert, or building-stone. Fossil lists are given from each exposure of importance. A range table is given of the chief brachiopods and corals, and the palæontological sequence is compared with that occurring at Bristol and in the north of England.

Chemical Society, April 5.—Prof. R. Meldola, F.R.S., president, in the chair.—An improved apparatus for measuring magnetic rotations and obtaining a powerful sodium light: W. H. **Perkin**, sen. The improved apparatus consists of a short but very powerful coil carrying a powerful electric current. The coil is cased with steel, and has a 3-inch gun-metal tube through the centre, the interior of this being the position of the magnetic field. The glass measuring tubes are supported in this tube in a metal trough which can be kept at any required temperature. A method of obtaining a powerful sodium light was described, which consists in heating a platinum boat containing sodium chloride by a small oxygen-coal gas flame. This causes the sodium chloride to volatilise, and the vapour, passing into a flame produced by a large Bunsen burner, gives a very intense, yellow light, which can be maintained for a long time.—The rusting of iron: G. T. **Moody**. The explanation of rusting as a process involving the production of hydrogen peroxide, as advanced by Dunstan, is directly negatived by experimental evidence, which shows that atmospheric corrosion results first from the interaction of iron and carbonic acid, whereby ferrous salt is formed, and subsequently from the more or less complete oxidation of ferrous salt by oxygen. It is found, moreover, that the composition of iron rust is not fairly represented by the formula $Fe_2O_2(OH)_2$, as stated by the foregoing investigator.—The estimation of carbon in soils: A. D. **Hall**, N. H. J. **Miller**, and N. **Marmu**. The soil is treated with chromic acid, and the resulting gases passed over a short length of copper oxide. The carbon dioxide formed is absorbed by alkali and estimated by double titration.—Electrolysis of salts of $\beta\beta'$-dimethylglutaric acid: J. **Walker** and J. K. **Wood**.—Bromo- and hydroxy-derivatives of $\beta\beta\beta'\beta'$-tetramethylsuberic acid: J. K. **Wood**.—Some new *o*-xylene derivatives: G. **Stallard**.—A new solvent for gold, preliminary note: J. **Moir**. The author finds that gold-leaf dissolves fairly readily when floated on an acid solution of ordinary thiocarbamide, and solution

is accelerated by the presence of an oxidising agent. The gold compound produced forms brilliant, colourless, six-sided lozenges, and contains 45·4 per cent. of gold.—The molecular condition in solution of ferrous oxalate, a correction: S. E. **Sheppard** and C. E. K. **Mees.**—Acetyl and benzoyl derivatives of phthalimide and phthalamic acid: A. W. **Titherley** and W. L. **Hicks.**—The dynamic isomerism of phloroglucinol: E. P. **Hedley.** The following conclusions were established:—(1) that in neutral solutions phloroglucinol exists in both modifications, the enol being greatly in preponderance over the keto-form; and (2) that this equilibrium is undisturbed by the class of solvent.—Studies in asymmetric synthesis, v., asymmetric syntheses from *l*-bornyl pyruvate: A. **McKenzie** and H. **Wren.**—*l*-Methyl*cyclo*hexylidene-(4)-acetic acid: W. H. **Perkin,** jun., and W. J. **Pope.**—Condensation of benzophenone chloride with α- and β-naphthols: G. W. **Clough.** —The constitution of coerulignone (cediret), a preliminary note: J. **Moir.**—A comparative crystallographic study of the perchlorates and permanganates of the alkalis and the ammonium radical: T. V. **Barker.** On comparing the perchlorates with the permanganates, it is found that the effect of replacing an atom of chlorine by one of manganese is much the same as that induced by the substitution of sulphur by selenium, say, in the sulphates of the same metals. The crystallographic evidence for placing manganese in the seventh group of the periodic classification, so far as such evidence goes, is therefore of the strongest possible kind.—Contribution to the theory of isomorphism based on experiments on the regular growths of crystals of one substance upon those of another: T. V. **Barker.**—Constitution of salicin. Synthesis of pentamethylsalicin: J. C. **Irvine** and R. E. **Rose.** It is shown that salicin (and hence also helicin and populin) contains the same γ-oxidic linking as the methylglucosides and sucrose.—A product of the action of *iso*amyl nitrite on pyrogallol: A. G. **Perkin** and A. B. **Steven.** The main bulk of the product formed in this reaction has the composition $C_6H_4O_3$, and it appears likely that it may consist of hydroxy-*o*-benzoquinone.—A reaction of ellagic and flavellagic acids: A. G. **Perkin.** Ellagic acid is oxidised by sulphuric acid to a compound having the formula $C_{14}H_{16}O_{10}$. Flavellagic acid yields a similar oxidation product.—Some thio- and dithio-carbamide derivatives of ethyleneaniline and the ethylenetoluidines: O. C. M. **Davis.**

DIARY OF SOCIETIES.

THURSDAY, APRIL 26.

ROYAL INSTITUTION, at 5.—The Digestive Tract in Birds and Mammals: Dr. P. Chalmers Mitchell.

SOCIETY OF ARTS, at 4.30.—Seistan, Past and Present: Colonel A. H. McMahon.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Long Flame Arc Lamps: L. Andrews.

MATHEMATICAL SOCIETY, at 5.30.—Perpetuants and Contraperpetuants: Prof. E. B. Elliott.—(1) A Question in the Theory of Aggregates; (2) The Canonical Forms of the Ternary Sextic and Quaternary Quartic: Prof. A. C. Dixon.—On the Question of the Existence of Transfinite Numbers: P. E. B. Jourdain.—Some Theorems connected with Abel's Theorem on the Continuity of Power Series: G. H. Hardy.—On a Set of Intervals about the Rational Numbers: A. R. Richardson.—On Two Cubics in Triangular Relation. Prof. F. Morley.—On the Accuracy of Interpolation by Finite Differences: W. F. Sheppard.

FRIDAY, APRIL 27.

ROYAL INSTITUTION, at 9.—Ore Deposits and their Distribution in Depth: Prof. J. W. Gregory, F.R.S.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Petroleum Fuel in Locomotives on the Tehuantepec National Railroad of Mexico: Louis Greaven.

PHYSICAL SOCIETY, at 5.

AËRONAUTICAL SOCIETY, at 8.—The Use of the Balloon in the National Antarctic Expedition: Captain Robert Falcon Scott, R.N.—The Experiments of the Brothers Wright: Sir Hiram S. Maxim.—The Carrying Power of Aeroplanes: M. José Weiss.

MONDAY, APRIL 30.

INSTITUTE OF ACTUARIES, at 5.—Reversionary Securities as Investments: C. R. V. Coutts.

TUESDAY, MAY 1.

SOCIETY OF ARTS, at 4.30.—Social Conditions in Australia: Hon. J. G. Jenkins, Agent-General for South Australia

ZOOLOGICAL SOCIETY, at 8.30.—Additional Notes on Anthropoid Apes, with Exhibition of Specimens: Hon Walter Rothschild.—On Mammals collected in South-west Australia by Mr W. E. Balston: Oldfield Thomas, F.R.S.—On the Lepidoptera collected during the Recent Expedition to Tibet: H. J. Elwes, F.R.S., and Sir George Hampson, Bart.

WEDNESDAY, MAY 2.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Fourteenth "James Forrest" Lecture: Unsolved Problems in Metallurgy: R. A. Hadfield.

SOCIETY OF ARTS, at 8.—Submarine Signalling: J. B. Millet.

ENTOMOLOGICAL SOCIETY, at 8.

SOCIETY OF PUBLIC ANALYSTS, at 8.—The Estimation of Fat in Homogenised Milk: H. Droop Richmond.—Milk Analysis: H. Droop Richmond and E. H. Miller.—Note on the Composition of Saffron: A. E. Parkes.—On the Polenske Method for the Detection of Cocoanut Oil in Butter: Dr. S. Rideal and H. G. Harrison.—On the Presence and Detection of Cyanogen in Java and other Beans: R. R. Tatlock and R. T. Thomson.—On the Examination of Linseed, Olive and Other Oils: R. T. Thomson and H. Dunlop.

THURSDAY, MAY 3.

ROYAL SOCIETY, at 4.—Election of Fellows.—At 4.30.—*Probable Papers*: On a Static Method of Comparing the Densities of Gases: Prof. R. Threlfall, F.R.S.—The Stability of Submarines: Sir William H. White, K.C.B., F.R.S.—The Action on Bacteria of Electrical Discharges of High Potential and Rapid Frequency: A. G. R. Foulerton and A. M. Kellas. —The Action of Pituitary Extracts upon the Kidney: Prof. E. A. Schäfer, F.R.S., and P. T. Herring.

ROYAL INSTITUTION, at 5.—The Digestive Tract in Birds and Mammals: Dr. P. Chalmers Mitchell.

CHEMICAL SOCIETY, at 8.30.—The Relation between Absorption-Spectra and Chemical Constitution, part v.: The *iso*Nitroso-compounds: E. C. C. Baly, E. G. Marsden, and A. W. Stewart.—The Action of Tribromopropane on the Sodium Derivative of Ethyl Malonate, part ii.: W. H. Perkin, jun., and J. L. Simonsen.—Brazilin and Hæmatoxylin, part vii., Some Derivatives of Brazilein: P. Engels, and W. H. Perkin, jun.—Pipitzahoic Acid: J. M. Sanders.—The Constitution of the Hydroxides and Cyanides obtained from Acridine, Methyl-acridine and Phenanthridine Methiodides: C. K. Tinkler.—The Constitution of Ammonium Amalgam: E. M. Rich and M. W. Travers.—Action of Light on Potassium Ferrocyanide: G. W. A. Foster.

LINNEAN SOCIETY, at 8.—Origin of Gymnosperms (*Continuation of Discussion*): Dr. D. H. Scott, F.R.S.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Some Observations on Bacterial Tank Operations: Dr. W. O. Travis.
